SCIENCE, LITERATURE, AND ART.

VOL. III.

LONDON
PRINTED BY SPOTTISWOODE AND CO.
NEW-STREET SQUARE

A DICTIONARY

OF

SCIENCE, LITERATURE, & ART:

COMPRISING

THE DEFINITIONS AND
DERIVATIONS OF THE SCIENTIFIC TERMS IN
GENERAL USE, TOGETHER WITH THE HISTORY AND DESCRIPTIONS OF THE
SCIENTIFIC PRINCIPLES OF NEARLY EVERY BRANCH
OF HUMAN KNOWLEDGE.

NEW EDITION,

EDITED BY

W. T. BRANDE, D.C.L. F.R.S.L. & E.

LATE OF HER MAJESTY'S MINT

AND THE

REV. GEORGE W. COX, M.A.

LATE SCHOLAR OF TRINITY COLLEGE,
OXFORD.

IN THREE VOLUMES.

VOL. III.

LONDON:
LONGMANS, GREEN, AND CO.
1867.

ADVERTISEMENT

TO

THE THIRD VOLUME.

THE PUBLICATION of this Volume has been delayed, in part by difficulties inseparable from the vast range of the work, but chiefly by the lamented death of Professor BRANDE, under whose care the first edition of this Dictionary was published six-and-twenty years ago. In recording his sincere regret that Professor BRANDE was not permitted to see this edition carried through the press, the Editor expresses a feeling which will be shared by all who knew him. The singular clearness and energy of mind, which enabled him to continue his editorial labours at the age of eighty years, seemed to warrant the hope that he might live to see the reappearance of this work in a form suited to the more stringent requirements and the wider knowledge of the present time. Although this was not to be, he yet had the rare happiness of being able to carry on his work to the eve of his death.

Professor BRANDE had thus in great part revised the articles which relate to his own subjects; but his editorial duties have since his death devolved on the present Editor, who desires now to acknowledge gratefully the ability with which the contributors have performed each his allotted task. The fulness and accuracy with which they have treated their several subjects render it necessary only to express a hope that throughout the book, and especially in all controverted or doubtful matters, the articles may be found to exhibit a judicially strict impartiality, which, while stating indifferently the opinions maintained by conflicting schools or parties, leaves it to the reader to draw his own conclusions from the evidence of facts laid before him.

LIST OF CONTRIBUTORS.

General Editor	W. T Brande, F.R.S.L. and E., late of Her Majesty's Mint, and Honorary Professor of Chemistry in the Royal Institution of Great Britain.
Joint-Editor	The Rev. George W. Cox, M.A. late Scholar of Trinity College, Oxford.
Agriculture	John Chalmers Morton, Editor of the 'Agricultural Gazette,' &c.
Architecture, History, Language, Logic, Mythology, and General Literature	The Rev. George W. Cox, M.A.
Astronomy, Observational and Descriptive, and Meteorology	E. Frankland, Ph.D. F.R.S. Professor of Chemistry in the Royal Institution of Great Britain; and J. N. Lockyer, Esq.
Biological Sciences, comprising Anatomy, Physiology, Zoology, and Palæontology	Professor Richard Owen, F.R.S. LL.D. D.C.L. Superintendent of the Natural History Departments, British Museum; and C. Carter Blake, Ph.D. F.G.S. Foreign Associate of the Anthropological Society of Paris.
Botany and Gardening	John Lindley, F.R.S. F.L.S. late Emeritus Professor of Botany in University College, London; and Thomas Moore, F.L.S. Curator of the Botanic Garden, Chelsea.
Building and Engineering	G. R. Burnell, Architect and Civil Engineer, F.R.I.B.A. F.G.S. F.S.A.; and John Bourne, Civil Engineer.
General Chemistry and Physics	W. T. Brande, D.C.L. F.R.S.L. & E.; E. Frankland, Ph.D. F.R.S.; John Attfield, Ph.D. F.C.S. Director of the Laboratories of the Pharmaceutical Society of Great Britain; John Broughton, B.S. Assistant in the Chemical Laboratory of the Royal Institution; W. F. Barrett, Assistant in the Physical Laboratory of the Royal Institution; and Herbert McLeod, Demonstrator of Chemistry in the Royal School of Mines.
Geology, Physical Geography, and Hydrology	D. T. Ansted, M.A. F.R.S. F.G.S. &c. Hon. Fellow of King's College, London.
Law, History, and General Literature	Herman Merivale, M.A. C.B. late Fellow of Balliol College, Oxford.
Law	Arthur P. Whately, M.A. of Lincoln's Inn, Barrister-at-Law; late Student of Christ Church, Oxford.
Mathematics, Pure and Applied	T. A. Hirst, Ph.D. F.R.S. Professor of Mathematical Physics in University College, London.
Military Subjects	Capt. Henry Brackenbury, R.A. F.S.A. Assistant-Instructor in Artillery, Royal Military Academy, Woolwich.
Mineralogy	Henry William Bristow, F.R.S. F.G.S. Honorary Fellow of King's College, London; of the Geological Survey of Great Britain.
Music	Professor W. Pole, F.R.S. Mus. Bac. Oxon.
Naval Subjects	Denham Robinson.
Navigation	H. W. Jeans, F.R.A.S. Royal Naval College, Portsmouth.
Painting and the Fine Arts	Ralph N. Wornum, Keeper and Secretary of the National Gallery.
Political Economy	The Rev. James E. Thorold Rogers, M.A. Professor of Political Economy, Tooke Professor of Economic Science and Statistics in King's College, London.
Printing, Bibliography, &c.	R. J. Courtney, Superintendent at Messrs. Spottiswoode & Co.'s Printing Office.
Theology and Ecclesiastical Literature	C. Merivale, B.D. Chaplain to the Speaker of the House of Commons; and the Rev. George W. Cox, M.A.

DICTIONARY

OF

SCIENCE, LITERATURE, AND ART.

Poles and Polars. The locus of the harmonic centres of the $(n-r)^{th}$ order, taken with respect to a point or *pole* o, of the n intersections of a given curve C_n by a transversal which constantly passes through o, is called the r^{th} *polar* of o with respect to the given (*primitive*) curve C_n. It is itself a curve of the $(n-r)^{th}$ order [HARMONIC CENTRES], and possesses very important properties. Each point in the plane, therefore, has $(n-1)$ distinct polars of the orders $n-1$, $n-2$, . . . 2, 1, respectively. The last or $(n-1)^{th}$ polar is called also the *polar line*, and the last but one or $(n-2)^{th}$ the polar conic, or quadric, the $(n-3)^{th}$ polar the polar cubic, and so on. From the properties of harmonic centres it follows at once that any polar of a point o is itself a polar of the same point with respect to each of the systems of polars of higher order than itself. Thus the r^{th} polar of o with respect to C_n is at one and the same time the $(r-1)^{th}$ polar of the 1st polar of C_n, the $(r-2)^{th}$ polar of the 2nd, the $(r-3)^{th}$ polar of the 3rd, and so on. As a special case the polar line of o with respect to C_n, is at the same time the polar line of o with respect to all the other polars of C_n, considered respectively as primitive curves. From the properties of harmonic centres, too, it follows that the locus of the pole m whose r^{th} polar passes through a fixed point o is the $(n-r)^{th}$ polar of o. Thus the polar line of o is the locus of all points whose first polars pass through o, and further, the first polars of all points of a line constitute a pencil of curves of the $(n-1)^{th}$ order, passing through the same $(n-1)^2$ points; these are the *poles* of that line. When the primitive curve is a conic, each point in the plane has, of course, but one polar, the polar line, and each line but one pole; in this case, too, the polar is simply the locus of the harmonic conjugate of the pole with respect to the points of intersection of the conic by any transversal through this pole. The polar of a point on the conic itself is the tangent at that point; indeed, generally, the polars of a point o situated on the primitive curve C_n, all touch the latter in o, the common tangent being, of course, the polar line of o. The first polar C_{n-1} of any point ρ is the locus of the points of contact of all tangents drawn from o to the primitive curve; so that $n\,(n-1)$, or the number of intersections of C_n and C_{n-1}, is the maximum, and in general the actual number of such tangents; this number, therefore, indicates the *class* of the curve. Should the primitive curve possess multiple points, however, every first polar will pass through them, and the $n\,(n-1)$ intersections of the latter with C_n will not all be the points of contact of tangents from o. Thus if C_n has a double point at d, the 1st polar C_{n-1} of o will pass through it, and be there touched by the harmonic conjugate of $d\,o$ with respect to the two tangents to C_n at d. This point d, therefore, will count for *two* amongst the $n\,(n-1)$ intersections of C_n and C_{n-1}. If C_n have a cusp at c, C_{n-1} will not only pass through it, but will be there touched by the cuspidal tangent, so that c will count for three amongst the intersections of C_n and C_{n-1}. We thus arrive at the result that the class of a curve of the n^{th} order, which has d double points and k cusps, is $n\,(n-1)-2\delta-3\kappa$. This is the first of Plücker's well-known equations. [SINGULARITIES OF CURVES.]

The subject of poles and polars will be found treated algebraically in Dr. Salmon's *Higher Plane Curves*, and geometrically by Steiner in Crelle's *Journal*, vol. xlvii. 1854, and by Cremona, in his *Teoria geometrica delle Curve Piane* (Bologna 1862).

Poles and polars with respect to surfaces have a precisely similar definition. Their numerous and very important properties are treated with great ability by Dr. Salmon in his *An. Geom. of Three Dimensions*.

Pole-axe. A long axe much used as an offensive weapon in the middle ages. It ap-

pears frequently in the Bayeux tapestry. [BATTLE-AXE.]

POLE-AXE. In the Navy, a heavy hatchet having a handle fifteen inches long, and a sharp point bending downwards on the side opposite the blade. It is used in boarding or resisting boarders, for the purpose of cutting ropes or nettings, and as a weapon.

Pole-mast. A mast consisting of one piece of timber as opposed to a made-mast, which is built of several pieces ringed together.

Polecat. The *Putorius fœtidus* of zoologists. It is common in England, where its white variety (*P. fœtidus furo*) is often domesticated under the name of ferret. The ferret and polecat readily intermix to the production of a fertile offspring.

Polemarch (Gr. πολέμαρχος). A name applied by the Greeks to magistrates intrusted with the military affairs and expeditions of a state. Such offices are found in Sparta and some Bœotian cities; at Athens the polemarch was one of the nine archons. [ARCHON.]

Polemoniaceæ (Polemonium, one of the genera). The name of a natural order of perigynous Exogens referred by Lindley to the Solanal alliance. They are mostly herbs, some of them being ornamental garden plants, and are distinguished by having five free stamens, axile placentæ, and straight plano-convex cotyledons. It comes near *Hydrophyllaceæ*, but the placentation is different. Among the genera which are esteemed in gardens may be mentioned *Phlox* and *Polemonium* as herbaceous perennials; *Gilia*, *Leptosiphon*, *Collomia*, and *Ipomopsis*, as annuals and biennials; and *Cobœa* and *Cantua* as greenhouse plants. In *Collomia* the mucous covers of the seed consist of an infinite number of delicate spiral vessels, which form a kind of cloud around the seed when it is thrown into water, by their rapid uncoiling and extension.

Polemoscope (Gr. πόλεμος, *war*, and σκοπέω, *I view*). An instrument, imagined by Hevelius, for seeing objects which cannot be seen by direct vision. It consists of a mirror placed obliquely in a tube or box, having an opening in the side opposite the mirror, so that rays from any object falling on the mirror are reflected to the eye of the spectator. Hevelius chose the name of *polemoscope* because he thought the instrument might be applied, in time of war, to discover what was going on in the camp of the enemy, while the spectator remained concealed behind a wall or other defence, and therefore could not employ a telescope. Opera-glasses are sometimes constructed on this principle, for the purpose of enabling a person to see others on the right or left, while he appears to look straight forward.

Polenta (Ital.). Corn meal mixed with cheese and made into a kind of pudding forms a dish which the Italians call *polenta*. The article sold in London under the name of polenta is the meal of Indian wheat or maize.

Polhode (Gr. πόλος, and ὁδός, *a route*). A quartic curve of double curvature which may be defined as the locus of the point of contact with an ellipsoid of a tangent plane common to it and a concentric sphere. The curve owes its name to Poinsot, who employed it in his remarkably lucid exposition of the rotation of a body around a fixed point. [ROTATION.] It is a closed curve whose axis of symmetry is the major or minor axis of the ellipsoid, according as the radius of the concentric sphere is greater or less than the mean semi-axis. When this radius and the mean semi-axis are equal, the polhode degenerates into two equal ellipses whose planes intersect in the mean axis. The orthogonal projection of a polhode on the plane of the major and minor axis of the ellipsoid is always a hyperbolic arc, and of its projections on the other two principal planes, one is always an ellipse, and the other an elliptic arc. If a, b, c, h, represent, respectively, the semi-axes of the ellipsoid, and the radius of the sphere, the polhode is obviously represented by the two equations

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}+\frac{z^2}{c^2}=1,\ \frac{x^2}{a^4}+\frac{y^2}{b^4}+\frac{z^2}{c^4}=\frac{1}{h^2},$$

from which the above, as well as all other properties of the curve, may be readily deduced. For the associate of the polhode, in Poinsot's theory, see HERPOLHODE.

Polianite (Gr. πολιός, *grey*). A deutoxide of manganese, differing from Pyrolusite in its greater hardness and pale steel-grey colour. It occurs in short and vertically striated right-rhomboidal prisms, also in granular masses, in Bohemia, Saxony, Thuringia, Siegen in Prussia, and also in Cornwall.

Police (Gr. πολιτεία, *government*). This term is used to designate those minor but highly important functions of administration, by which protection is afforded to persons and property; crime and outrage are prevented, or, if not prevented, detected; and lastly, public wealth defended by sanitary and other regulations. The maintenance of these and other social advantages or necessities is a matter of police; though, in fact, the word is commonly employed in a narrower sense for the constabulary force, which, superseding the relics of the old manorial or parochial system, has been very effective in the performance of some among these functions.

The ancient police was the view of frankpledge, and the superintendence of the manor court. [MANOR.] When this system became obsolete, the constable or tything man, and the watchmen in towns, became the very inefficient conservators of the public peace. The author of the modern English police force was the late Sir Robert Peel, whose legislation in this direction has been stereotyped in the vulgar name given to the policeman, *peeler*. The police force is either open or secret. The ordinary policeman is dressed in a particular uniform, known to everyone, and his operations are limited to a particular region called his *beat*, and which has been handed down from the days of the watchmen. A secret police is one which is distinguished neither by dress nor demeanour from ordinary citizens, and its duty is to detect crime,

and if possible to prevent it, by obtaining all such information as could not be arrived at by any ordinary method. There is, of course, some danger lest a secret police should stimulate the crime which it is employed to prevent, and there is little doubt that in old days the detective was too often the master of thieves. A secret police employed for political purposes is the most odious form which the detective may assume, and that which is most likely to be turned to the worst ends.

The metropolitan police is under the general management of a public officer whose head office is in Scotland Yard. The city police is, however, controlled by the corporation, and a late attempt made to amalgamate the two forces has been baffled. The police in towns is generally under the control of the municipal authorities, while the chief officer of the county police is the chief constable of the county. The police system has been gradually extended over the whole country.

The police in Ireland is different from that in England, being armed, and generally of a military character. The apology for such a force, with duties divergent from those supposed to belong generally to civil officers, has been found in the disturbed state of Ireland, and the frequency of outrages. In 1862, the police force of the city of London was 628, of the rest of the metropolis 6,566, of the boroughs 6,286, of the counties 7,969, of the dockyards 712. Total for England and Wales, 22,161; and the cost was 1,596,994*l.* Towards this charge 385,701*l.* was contributed from the Treasury.

Policy. This word, as applied in Life Assurance, is in Mr. Wedgwood's opinion (*Dictionary of English Etymology*) a violent corruption of the Greek πολύπτυχον, sc. γραμματεῖον, *tablets folded into many leaves*, which were used when the Diptych was not large enough to contain the writing. The word is found in the transition forms *puleticum, polaticum, potlegium*. [Assurance.]

Polishing (Lat. polio, *I make smooth*). In Sculpture, the operation of giving a smoothness and gloss to any surface. The polishing of marble is effected by first rubbing the surface with freestone; after which it is wrought upon with pumicestone; and lastly with the finest emery powder, from which the glossy surface is obtained.

Polishing Slate. The *Polierschiefer* of the German mineralogists. A light slaty substance found abundantly at Bilin in Bohemia: it consists of the silicious shields of microscopic animals.

Political Arithmetic. In the works of the earliest economical writers, as Petty, Davenant, and Gregory King, this term was employed to designate the science which now goes under the name of *political economy* or economic science. In fact, the greater part of the theories alleged by these writers were founded on numerical calculations, and very few of their works contained the enunciation of principles, and the vindication of rules. In later times political arithmetic is identified with Statistics.

Political Economy. The science of those forces which operate upon the social faculties of man, in so far as the products of such faculties and forces are in demand, and may be estimated by some recognised measure of value. Political Economy is generally defined as the science of the laws which govern the production, distribution, and consumption of wealth; but most of the terms employed in this definition are ambiguous. Wealth is sometimes used for the sense of satisfaction felt by an individual in his ability to procure anything which he may desire; sometimes for the comparative capacity of nations stimulated to acquisition, not only by the impulse to individual gain, but by mutual rivalry. Again, wealth is sometimes used for a product, and is therefore limited to material objects, sometimes for a state, in which powers as well as products are reckoned. Again, the word *production*, though the least ambiguous of the technical terms which comprise the common definition, is variously interpreted; sometimes as containing mechanical labour only, sometimes as embracing the training of mechanical labour, rarely as including all the subsidiary processes, by which mechanical labour is rendered efficient, continuous, and trustworthy. The term *distribution* is also equivocal; it stands with economists for the portion which the several members of society receive as their share out of the gross produce, but it may also mean, and often does mean, the method by which the products of one kind of labour are exchanged against the products of another kind. And lastly, consumption is either productive or unproductive, the former being understood to mean that application of the profits of labour which is destined for future production, the latter such expenditure as is not so destined. But as rest is as essential to the continuity of labour as exertion itself, we can scarcely maintain (unless the expenditure be vicious or mischievous) that consumption, ostensibly unproductive, is not or may not be indirectly a means, and a necessary means, for future production. And thus it may be said, that although the definition commonly given by economists, is sanctioned by custom and authority; its exceedingly ambiguous character is continually provoking discussion as to the fundamental limits of the science, and involving the repetition of a number of cautions which need not be given, were the terms by which political economy is to be defined, rendered sufficiently distinct and clear.

Political economy is a science, i. e. it deals with laws uncontrollable by human volition, and with phenomena derived by inevitable sequence from these laws. In common language, we may speak of the violation of an economical law. By this we mean merely, that the occurrence of one course of action will give rise to certain phenomena, and the adoption of a contrary course will be followed by contrary phenomena. On the hypothesis of in-

dustry, i.e. of a desire for material improvement, the adoption of free trade will be followed by material prosperity, while every act which hinders the voluntary energies of men is pro tanto a bar to material progress. The rise follows the other as certainly as vegetation springs from light, heat, and moisture, and as the cessation of organic growth is the result of cold, darkness, and drought. Free exchange, in short, is a fundamental condition in political economy. We can indeed interpret, in the presence of limitation violently put on economical action, what will be the material consequences, but we cannot judge or predict the benefits of free action, unless we have experience of the results which ensue from its unshackled adoption. The real benefits of freedom can be understood only by its extension, and as yet the most advanced public policy has only entered upon the vestibule of its temple, and had experience of a part of its operation.

The elements with which economical action deals, are those which reside in materials bestowed by nature. If these elements are limited, as those of land in settled countries, water in motion, and the like, a demand may arise for them on their appropriation, from the very fact of their being limited, and this appropriation may take place, irrespectively of the quantity which may be used, by any municipal regulations which prevent occupation. If they are unlimited, their value is derived from the labour bestowed on their appropriation. Thus the force of wind, the power of steam, and the like are unlimited elements; but in order that they may be rendered available, labour must be bestowed upon their use, and thus they become valuable, not in themselves, but because they have become products of labour. The forces which stimulate the faculties to make such an appropriation, are partly personal and partly social; personal in so far as self-interest is the motive principle of all economical labour, social because the largest individual benefit is derived from the most complete reciprocity of services. Hence the true growth of economical principles leads to the fullest international association, and the closest identity of all such interests as can possibly be made of reciprocal benefit. Every man who wishes to exchange comes with a benefit to the other man with whom the exchange is to be effected; each person is a buyer, each a seller, and each values that which he receives at a higher rate than he values that which he bestows. If the object received be of no greater value than that which is offered, no exchange takes place; and therefore the doctrine that a foreigner's gain in trade with any country is a loss to the country trading with him, is a position as false as it is mischievous. In order that the object should be desirable, it must needs have had labour expended on it. No man will give of his own, in order to obtain some other thing which is as much in his possession as it would be in any other man's. Under certain circumstances, indeed, it does not follow that the individual's labour must be hard; it may be exceedingly slight; but the value of the article which he offers must be proportioned to the average amount of labour expended on its production. A man may procure, perhaps, by the mere labour of stooping to pick it up, a diamond worth 10,000*l.*, but it is worth so much, not because of the amount of labour which he has bestowed, but because it takes on an average ten thousand pounds' worth of labour in order to obtain a similar stone.

Furthermore, the utility or service or benefit, must be appraised by some standard. This is, as we know, familiarly, money. Not that money itself is useful to the individual; it is a pledge, taken because certain to be redeemed, that the future demands of the recipient can be satisfied with it. But the use of a measure (even though no money actually passes, but only a debt or credit in behalf of the seller is created) is necessary for commercial transactions. It may be doubted whether any progress can be made in civilisation without some such medium, that is, at least, without some habitual estimate of values by a recognised standard. At any rate, the existence of such a standard is discoverable in the earliest civilisation. Many services may be rendered to mankind, the value of which is immense, but the commercial estimate of which is necessarily wanting. No compensation can be made for wise statesmanship, for sound instruction in public and private duty, for rectitude and integrity of life, for the qualities which we venerate and trust. [LIBERTY.] Without them, the world would be a desert inhabited by a few savages; with them it becomes possible that the maximum number of the human race should subsist with the maximum of comfort and convenience. They are therefore postulates of the best economical state, but they are not appreciable values, because no measure of the service can be rendered in money or money's worth, because moreover they are not subsequent on any demand, but precede it, by the fact that they enlighten society as to the fundamental and permanent advantage of moral goodness. Truth, honour, and virtue cannot be taken into account by an economist, because, valuable as they are, they cannot be economically estimated; but no one except a doctrinaire would forget or ignore them.

Moralists are well acquainted with the influence of two coexistent springs of action: (1) that which lays down an external standard of action, which impels towards community of sentiment and action, which acts upon conscience and conviction; and (2) that which is a mere logical interpretation of objects according to the dictates of personal interest or convenience. To say that both are equally busied with the interpretations of personal utility is an abuse of terms, for the distinction between the two is fundamental in civilised thought and language. To say that they coincide in the best practice of human life is to admit what all would anticipate, the fact, namely, that natural impulses

are capable of mutual harmony. It is part, therefore, of the great analytical utility and the wide practical sagacity of Adam Smith, that while he developed an economical theory from the personal or selfish instincts of man, he framed an ethical theory of human nature by ascribing morality to the force of human sympathy. It is true that this theory seems and is one-sided, but taken in conjunction with the economical aspect of man's nature, it will be found to give a more coherent estimate of ethics than is commonly found.

Political economy is to history what logic is to morals—the analysis, namely, of the conscious process by which a nation or an individual thinks and acts. Hitherto, indeed, the economical interpretation of history has made but little progress, partly because materials have been wanting, partly because the habit of historical enquiry has tended rather, in so far as the philosophy of history has been developed, towards legal, military, and diplomatic researches. But to take a few examples, the great political position of the Italian republics in the middle ages was entirely due to their economical position, to the fact of their being the financiers of Europe. Their rivals, the popes of the same epoch, were capitalists, whose resources were freely used for purposes of personal ambition or of diplomatic influence. The trade of Europe with the East, passing partly through Egypt, and partly through the valleys of the Tigris and Euphrates, over the highlands of Armenia to Trebizond, or southwards to Licia (i.e. Seleucia) was monopolised by the Genoese and Venetians. All this supremacy passed away with the simultaneous discovery of the Cape passage and the New World; and the voyages of Vasco da Gama and Columbus, purely commercial in their beginning, tended as much to the Reformation and the downfall of the ancient diplomatic centres, as any theological speculations or political changes. Similarly, the great position occupied by this country during the thirteenth and early part of the fourteenth centuries, is to be assigned far more truly to economical causes than to the disintegration of the French monarchy, and the decline of Italian liberty. During the long and obscure reign of Henry III., great social progress had been made in England. The harsher features of villenage had been effaced; and in all likelihood a minute search among the abundant materials existent for the economical and social history of the century contained in the reigns of the three Edwards would fail to discover any trace of actual slavery in England, or, indeed, anything but fixed labour rents commutable for money, and coupled with permanent tenure. A contrast between the condition of the English peasants and the material of the population of France would be quite sufficient to account for the military preponderance of this country during the period adverted to. Between the insurrection of the Jacquerie in the middle of the fourteenth century, and that of the English peasants at its close, there was, though they are regarded as similar events by Hallam, only a slight external resemblance—the former having been the uprising of desperate misery, the latter the attempted revolution of a prosperous class. In consequence the French peasant was forced back into still more abject servitude; the English occupier, baffled for a time, achieved his independence by the election statute of Henry IV.

In modern times, the laws and maxims of political economy are gradually becoming the staple of legislative and administrative politics, the business of government being more and more persistently directed towards the progress of economical prosperity, and the gradual extinction of practical errors. It is true that partly in consequence of the difficulty of persuading interests whose prosperity is likely in appearance to be compromised by changes, partly by the inherent conservatism of all administrations, and especially of those which are most despotic, and therefore most timid, the progress made is comparatively small; but to have begun at all is of no small consequence, and the general ventilation of economical questions is evidence that changes, the benefits of which are manifest and uniform, cannot long be delayed. Still more satisfactory, in this country at least, is the fulness with which economical laws are interpreted by society at large. For example, the cessation of supply from the cotton-producing districts in the United States, consequent upon the four years' war, completely paralysed the industry of a tenth part of the people in this country, and injured all by raising the price of a necessary of life. It may be confidently stated, that twenty years ago a like cessation of supply would have been followed by such discontent among the sufferers, as would have induced insubordination and riot, and the country would have witnessed on a large scale, during the recent cotton famine, excesses similar to the agrarian outbreaks of twenty or thirty years ago. As it was, all classes bore testimony to the patience with which the suffering was endured. It was endured, because the parties most interested were aware that the deficiency was caused by circumstances with which all administrative or diplomatic skill would be perfectly incompetent to deal—because, in other words, they were generally acquainted with the economical conditions of supply and demand. It may be hoped that, hereafter, the same acquaintance with the true relations of labour and capital will put an end to the unjust and mischievous operation of trades' unions, and that protected labour will be seen to occupy as immoral and indefensible a position as protected capital.

The great advantage supplied by an acquaintance with the laws of political economy lies in the fact that it determines distinctly what must happen from a course of commercial or social policy which is consonant with its precepts, or repugnant to them. It is a science, because it can predict with certainty the phe-

nomena which will ensue from a particular line of action, in so far as it has been hitherto possible to analyse the elements from which the result will come, and interpret and account for all the forces which contribute to the event. Of course it has its problems, and it has been the subject of hasty and erroneous generalization. But its leading and accepted principles are as certain as any other natural laws, and are as little liable to suspension or modification. It is because it is thus rigid and precise that political economy has been censured as a harsh, or, as Mr. Carlyle has called it, a dismal science. But we may as well call physiology a dismal science, because it points out the necessary consequence of violating sanitary or dietetic rules. It is of the highest value to know what are the limits of voluntary action, and what is the inevitable result of a natural law. For the contrast between the laws of political economy and the averages of statistics, see STATISTICS.

The various terms employed by economists, as CAPITAL, EXCHANGE, LABOUR, PROFIT, RENT, TAXATION, WAGES, will be found treated under their proper heads. The remainder of this article will be devoted to a short history of the progress of political economy, and its position in ancient and modern systems of practical philosophy, and to a summary of the causes and conditions of comparative wealth.

It was not likely that this branch of social science would escape the investigation of the Greek thinkers. It was not likely that it would, except to a very limited extent, form a material for original thought under the despotism of the Roman empire, or even of the Roman republic. The Greeks did not, it is true, separate this portion of ethical and political science, and erect it into a distinct subject of enquiry. For, in the first place, the sphere of individual action, and that of political obligation, were far more closely identified by the Greeks than they are with us. [LIBERTY.] They held that man exists for the community, while we in modern times are far more disposed to hold that the community exists for the developement of individual purposes, and for the harmony of individual ends. Hence they controlled the conduct, the occupations, and opinions of men more severely than would be thought consistent with that liberty which we know to be the only guarantee of a true civilisation. And in the next place, the Division of Sciences, though commenced by Aristotle, was not, in the comparative scantiness of human information, ever carried out as it is now. Such a division of science, like the division of labour, is the result of accumulated information gathered from large and varied fields of enquiry. But the chief and most central axioms of political economy can be found in the works of these fathers of mental science. The magnificent romance of Plato, his ideal republic, is founded on the familiar economical law, that the best results are procured by a progressive division of occupations. The Politics of Aristotle contain some of the soundest definitions which can be found of some among the formulæ of political economy; as for instance, those of the functions of money and of the necessity of reciprocal benefit in all operations of exchange. The introductory chapter to this work might form an exordium to an economical treatise. The relations of credit to capital are determined with tolerable exactness in the Eryxias, a dialogue printed among the works of Plato, and generally assigned to the Socratist, Æschines. Not that the theories held by those ancient thinkers were one and all satisfactory and sound. They were totally unacquainted with the cardinal distinction between profit and wages, and hence held, in common with most ancient writers and politicians, the unlawfulness of interest.

The downfall of the Roman empire is traceable in no slight degree to the practical defiance of economical principles. M. Guizot, in his *History of Civilisation*, has shown how the fiscal regulations of the empire were fatal to the prosperity of the provincials, and we all know how wide-spread was the evil of slavery in the ancient world. It would seem, too, that any economical reform in the public policy of the Romans was dangerous in the highest sense to those who proposed and furthered it. The fate of the Gracchi and of the schemes which they furthered for the social improvement of Italy furnished a stern warning to all innovators. The authors of a necessary reform, and of a set of economical changes which were absolutely obligatory for the preservation of the national life, were murdered by the aristocracy, and by a most perverse destiny their names have been thenceforward identified with sedition, confiscation, and robbery.

In this country, the history of the science of political economy is one of a perpetual contest against administrative error. The earliest writing on the subject is perhaps the essay once ascribed to Shakspeare, but now known to be the composition of one Stratford, in which the high prices prevailing in England are discussed and traced to tamperings with the currency, as well as to a general rise in money values. The works of Mun, the author of the mercantile system, and long the great authority in that branch of political economy which deals with commerce and the exchanges, were directed against the unwise prohibitions on the exportation of the precious metals, the absolute inability of the enactments against those who were indifferent to breaking the law, and the vexatious and mischievous interference of the officers who succeeded to the functions of the king's exchanger. This great officer (the first, appointed by Edward III., being William de la Pole, an eminent merchant, and ancestor of those dukes of Suffolk who played so important a part in the civil broils of the fifteenth century) was regularly nominated by patent, and entrusted with the duty of prohibiting the export of the precious metals. The last who had a valid patent was Lord Burleigh, but he never

exercised his functions. Charles I. appointed the earl of Holland in 1628, but the goldsmiths petitioned against the appointment, and Selden in the House of Commons disputed the validity of the patent.

Mun was far from doubting the general truth of the popular theory, that wealth consisted in gold and silver, and that the only way in which communities which had no mines of the precious metal could become rich, was by taking care that an excess of payments in these metals should form the characteristic of successful trade. But his experience had taught him that trade with the East was impossible, unless permission were given for the exportation of specie. The East had always supplied, by an expensive and precarious route, those tropical commodities which the fashion of the time, and the hardships of social life in the middle ages, rendered in the greatest degree convenient, if not almost necessary. But the producing countries could be led to acts of exchange only by the offer of the precious metals, particularly silver, for India produces these metals in very small quantities, and has always absorbed a vast amount for purposes of currency, of display, and still more largely, in all likelihood, for hoarding. Thus Mun argued that the relaxation of these prohibitions, as far as the Indian trade was concerned, was not only essential to the trade with those regions, but also in the highest sense advantageous to the country, because the sale of these imported commodities in European markets would certainly procure a far larger amount of specie than had been previously exported. Hence Mun has been considered the author of the balance of bargains or mercantile system, in which it was admitted that the business of trade was to enforce and support the theory that the precious metals are wealth, though the means whereby this wealth should be secured were to be circuitous. At any rate, the theory was accepted, and for more than a century acted on.

The works of Petty, Davenant, and Gregory King are rather statistical than economical, and though the writings of the first and last of these authors are full of sagacious and practical observations, they can hardly be said to have contributed much to the progress of the science. The same criticism may be applied to the speculations of the various writers on banking and the currency, speculations which led, when sound, to such an establishment as the Bank of England, at Paterson's instance, and when unsound, to the wild schemes of Chamberlayn and Law, and the fraudulent jobbery of the South Sea scheme.

The true founder of the modern system of political economy was Adam Smith. The *Enquiry into the Nature and Causes of the Wealth of Nations* was published in 1776. It was aimed specially at the refutation of the mercantile theory, the protective system, the regulation of commerce by protective enactments, and the colonial theories then in full operation. Adam Smith was the first of modern economists to show what are the true functions of money, and what is the consequence of those errors which identify it with wealth; he proved incontestably that the protective method then and long afterwards supposed to be the only just and patriotic course of policy, was neither just nor expedient, that the notion of government being able to direct an individual's commerce or expenditure more discreetly than he ordinarily could himself, would be utterly absurd, if it were not exceedingly mischievous, and that by the system of colonial trade, which strove to execute the invidious and malignant project of excluding other nations as much as possible from any share in it, England had not only sacrificed a part of the absolute advantage which she, as well as every other nation, might have derived from that trade, but had subjected herself both to an absolute and relative disadvantage in every other branch of trade. Adam Smith was also the first to lay down a consistent theory of taxation, and to determine from an economical point of view the functions of government; and though it cannot be asserted that he was invariably right either in his principles or in his inferences from them, yet his work possessed not only the great merit of being the foundation of the most important and significant of the practical sciences, but also that of presenting the largest amount of novel but complete refutations of inveterate prejudices that ever perhaps had been collected in any single volume, together with the most lucid illustrations of the principles and inferences laid down and deduced. But among the other merits of this great work we must not lose sight of its geniality and warmth. It is true that the point of view necessarily taken by Smith was the existence and stimulus of personal and material interests. But he finds these interests not in a narrow and selfish satisfaction, but in the harmony and reciprocity of all men's good. It is in this way only that the science can be freed from those repulsive traits which have been made too prominent in its treatment by less comprehensive and generous minds. For unless the mutual service of men, and the mutual duty of all the units of which society is composed, be understood and enforced, there is no escape from that passion for personal advantage, that protection to particular interests, and that selfish and suicidal disregard for the good of others, of which the *Enquiry into the Wealth of Nations* is the happiest, the most energetic, and the most complete refutation. 'Adam Smith,' says one of the ablest and most profound of modern philosophers, Mr. Goldwin Smith, 'understood the value, moral as well as material, of property, but he also understood the relative value of property and affection.' (*Lectures on the Study of History*, 2nd edit. p. 162.)

Idle and crude as now seem many of the fancies which were exploded by the appearance

of Adam Smith's great work, it would be an error to imagine that the first refutation was unattended with difficulty. It costs very much to shake off prejudices in thought as well as it does to correct unseemliness or uncouthness in action. It needs great courage, complete abstraction, and cautious attention to meet and go counter to the current of popular opinion. The convictions of one generation commonly become, it is true, manifest errors to another; yet not less ingenuity is needed for the first refutation of a vulgar error, than for the discovery of a physical law or a mathematical method. We should measure the value of Adam Smith's labours not by a comparison between the results of his argument, and the shape into which his successors have put the science of which he was the author, but by contrasting the science as he left it, and the host of fallacies which, universally accepted before his time, were destroyed at once by his sagacity. Mr. Mill has done justice to the intrinsic power of his predecessor by acknowledging the great progress made by Smith, and the epoch which it forms in human thought.

Many systems of political economy have followed that of Adam Smith. We may mention among continental writers J. B. Say and Sismondi; while in England the first to carry on the enquiry into economical science were Malthus and Ricardo. But in this country, these and other writers have been rather distinguished as promulgating views more or less accurate on special points connected with the general subject, than for any fresh arrangement of the science itself. Thus, for a reason already adverted to—the fact, namely, that political economy has been developed more from a polemical than from a constructive impulse, and that its growth has been due more to assaults directed against real or supposed errors in practice, than to positive elaboration and synthesis—Malthus is distinguished rather as the author of the theory of population, Ricardo as an authority on the subject of rent and taxation.

It would be tedious to recount the names of the several persons who have handled with various success the general theory of the science, and still more difficult to enumerate those who have made large additions in detail to the several divisions under which the material is arranged, or have contributed cognate or auxiliary information and reasoning. Enquiries into subjects which have an economical value and are open to an economical estimate, are of great importance in the progress of the science, not only because they serve to elucidate and interpret the various and intricate problems which perpetually recur, and furnish material for debate and decision, but because political economy needs to be constantly illustrated, and (if need be) corrected by facts, while there is and probably will be a continual disposition to transport it into the domain of abstract theory, and thus very often to avoid the limitations and corrections by which a theory must be constantly attended. Mr. M'Culloch's work on the *Literature of Political Economy* is one of great value, and might be advantageously continued to the present time.

Mr. Mill has avowedly proposed in his valuable and important work to remodel the theory of Adam Smith, on the principle which clearly guided the first founder of the science; i. e. to unite abstract reasonings with abundant illustrations, and to associate the subject with social and political philosophy. We cannot here attempt any criticism of Mr. Mill's method or principles, nor would it be possible to enquire how far he has carried out the plan with which he prefaces his work. It is sufficient to say that the great and undoubted merits of this author have given him almost the position of an arbiter on economical questions, and have caused his authority to be eagerly appealed to in support of a course of temporary or permanent policy.

The Conditions and Causes of Comparative Public Wealth.—It is plain that wealth is not a quantity but a ratio. The wealth of mediæval Italy was great when compared with that of the decline of the Roman empire, and small when contrasted with the command possessed over the necessaries and conveniences of life by the poorest European nation at the present time. Similarly the wealth of no European state is comparable with that of England, and yet few European states possess less foreign trade and home manufacture than England possessed sixty years ago. And, again, wealth lies in the distribution, not in the appearance, of riches. One of the most coherent and long-lived delusions which has occupied the world, is the general impression of the wealth of India. Travellers and traders saw the accumulation of gold and precious stones possessed by the native princes and the wealthier classes, and concluded that the country was exceedingly rich. In fact, it is very poor, the great mass of the community subsisting on the smallest amount of the cheapest kind of grain. On the other hand, we have been continually informed by persons who have had no economical experience beyond European states, that the American government would inevitably collapse in consequence of the pressure of taxation and the drain upon the resources of the community by the enormous expenses of the war. Such critics have ignored the fact that wealth in the United States is very widely distributed, that the rate of wages and the rate of profit are very high, that the necessaries of life are abundant and cheap, and that therefore the margin of the income possessed by every one in excess of the requisite expenditure of the individual is wider perhaps than has ever been known at any other period of economical history in any state, and that therefore the means available for government expenditure were practically unlimited.

The first condition of wealth is personal freedom. There was great apparent wealth in ancient Rome; but wealth was in the hands of

a few, and the economical atmosphere was tainted with slavery. A slave-holding community never developes the mechanical arts, except to some small extent in the direction of military engines. And the reason is obvious. The most powerful cause towards the production of comparative wealth, is the impulse towards procuring the greatest possible results with the least possible expenditure of labour. But such a motive cannot be present when the mass of the community is deprived of all discretion over their labour and the fruits of their toil. Still more absolutely does a system of slavery prevent that division of labour by which labour is rendered most effective. Bad government differs from a state of slavery only in degree. The purpose of government, economically considered, is that of effecting certain services, which could not be rendered at all by individual action or voluntary combination, or could not by such action be effected so discreetly or so justly. If, however, a government transcends its functions, which are analogous to those of the division of labour, if it becomes one-sided, partial, negligent, or rapacious, if it fails to protect persons and property, and turns what activity it possesses to the interest of the ruler only and his dependents, all the evils of slavery ensue. Capital cannot be accumulated, the division of labour is prevented, the motives of production itself are ultimately destroyed, infinite moral and social evils ensue, and the community afflicted by such a scourge ultimately relapses into barbarism, and the country becomes a desert. Such is the history of the downfall of that prosperity which once characterised Asia Minor, the eastern parts of Central Asia, Egypt, and the coast of Northern Africa. Less in their effect, but similar, have been those interferences with private action which have characterised the policy of most modern governments. The trading monopolies of the time of Elizabeth and James I.; the privileges of corporate towns and guilds; taxes on occupations, restrictions upon adaptation—as are some patents; restrictions on localities or markets; taxes on articles of prime necessity with a view to furthering home production, and the whole machinery of protection and bounties; taxes on exports; hindrances put on the free circulation of capital and labour by usury laws and parochial settlements, and a host of other prohibitions and impediments, have seriously impaired, and will as long as they are persisted in seriously impair, the productive energies of those who are made subject to them.

Another condition is, that due security should be given to property. The right of enjoying and disposing of accumulations made by industry is manifestly one of the most powerful incentives to labour. No man will work unless security is given to him that he shall be able to appropriate freely the fruits of his labour; and there is nothing on which society is more sensitive and more easily alarmed than when any hindrance or limitation is put on the right of property, or any insecurity of possession threatened. But by parity of reasoning, all limitations laid by testament or grant of dead persons on the acts or powers of the living are hindrances to economical progress. They diminish the disposition towards improvement, because they diminish the fulness of the property possessed by individuals, as well as hinder alienation into the hands of those who have more capital with which to improve, and more inclination to do so.

A third condition is that the freedom of action should presume that individuals are the best judges of their own interests, and that therefore, as they ought not to be hindered, so they should not be helped. In other words, the rule of government should be in economical matters, *laissez-faire*. The reason is obvious. The inductions of the wisest government are generalities inapplicable to individuals, because circumstances are ever shifting, and therefore to be interpreted by an estimate of particular needs. Hence, primâ facie, the protection afforded to a nascent commerce by military display or force is radically bad, just as we now admit that the military defence of the colonies for the purpose of securing colonial markets was a delusion. Not indeed that the rule of *laissez-faire* is without exception. There are cases in which government is justified in interposing. An administration may tax a community in order to confer a great public benefit, as by making roads, or in order to secure large moral and material progress, as in compelling education, or to further the highest and best developements of art and science. But in these and similar cases, the defence of government interference is to be found in the facts that the voluntary association of individuals is incompetent to achieve these results, or that, the community not being yet alive to the worth of the service, and therefore exhibiting no demand, the government is justified in taking the initiative, and leaving the declaration of indemnity for such an invasion of private right to the subsequent judgment of a more enlightened and competent community.

The following appear to constitute the most powerful causes of comparative wealth: First, the division of labour. This cause of wealth was first commented on by Adam Smith, who showed that the distribution of employments induced greater dexterity in workmen, more unbroken continuity, and greater economy. This is the more manifest, when the division operates in the direction of aiding and supplementing industry by the addition of mechanical forces to human labour, or in some cases by the substitution of machinery for muscular efforts. Adam Smith, however, failed to recognise another very important result of the division of labour in cheapening the cost of production. If the whole process is done by one man, the cost of that portion of the work which needs the least skill is as great as that which needs the most, whereas by division it is possible to diminish the cost, by graduating the remuneration. And as the only limit to

the division of labour is the width of the market, it is clear that governmental regulations tending towards protection are in effect hindrances to the most powerful among the causes of comparative wealth.

Another cause is the accumulation of capital. It will be necessary to say a few words about capital and its functions, as this important term was passed over under its proper head with a very slight notice. The proceeds of labour are divided into three portions, that which is consumed for the enjoyment of the possessor, that which is employed for future production, and that which is reserved or hoarded for contingencies. In so far as the profits of labour are expended on mere enjoyment, i.e. on such gratifications as have neither directly nor indirectly any bearing on future production, the expenditure is mere consumption. The second kind of employment is, properly speaking, the function of capital; and the hoard or reserve, though not used productively, is an important resource when occasion arises. It is clear that all capital is the result of saving, i.e. it must consist of objects in demand, which are in excess of the wants or the desires of its possessor, and it is also clear, that in order to be effective, it must be consumed in some direction which shall be distinct from the immediate possessor of it. Further it must be consumed in the maintenance of labour, for the employment of capital is always with a view to profit, and profit, like every other kind of wealth, can be induced only by labour exercised upon materials and their properties. Hence the capital of a country represents all the saving which is employed in the maintenance of labour, and the increase of the capital of any country is relative to the amount which is annually accumulated over and above that which is expended in the maintenance of labour. If the expenditure were exactly tantamount to the charges incurred, so that an absolute balance were struck every year, the community would neither progress or retrograde; if it were in excess, capital would suffer diminution; if it were less, capital would accumulate. The absolute balance seems to have been almost struck in Holland at the close of the last century; the retrogression appears to have characterised Spain for the two and a half centuries following the reign of Charles V.; and the state of progress has been manifest in this country for the last 300 years, and is still more notably a feature in the growth of the United States. Capital, too, is divided into circulating capital and fixed capital. These terms are unfortunately rather ambiguous, but they are meant to distinguish those employments in which the capital changes its form and cannot be recovered in the same shape after it has discharged a single office, from those in which the same product is competent to perform a large number of operations. Thus the seed sown for a future crop is circulating capital, whereas the labour expended on the drainage of land or the building of houses is fixed. Money is a form of fixed capital, and the more thoroughly it is fixed, the larger will be the number of operations it is made to effect, or, in other words, the more will it circulate. Capital, moreover, is not, as we have seen before, money or even implements, but virtually food and necessaries for labour; i.e. money and implements are objects in which capital is fixed, and the former is a general credit, a power by which food and necessaries may be to a moral certainty attained, but it is clearly only as a purchasing power that it can be called capital; and instruments are capital embodied in a fixed form. The amount of capital possessed by a community, is the measure of the means by which the community can be stimulated to labour. Thus, as we have seen before [DEMAND], there may be an urgent call for the products of labour, but unless capital be present, in order that labour already existent may be called into activity, the demand will not be met by a corresponding supply; or, to quote Mr. Mill's adage, 'demand for commodities is not demand for labour.'

The effects of abundant capital on the progress of national wealth are, first, that it insures continuity of occupation; i.e. it enables producers to wait for the market. In countries where capital is scanty, and the mechanic or farm labourer is also the dealer, the price of commodities fluctuates largely, and yet is on the average high, because the producer has to take into account the suspension of his labour and the risks of the market. Such a state of things is inconvenient to both parties. It is an evil to the producer, because, while he is alternating between abundant employment and forced indolence, he is often obliged to suffer the loss of a forced sale. It is an inconvenience to the consumer, because he is exposed to great fluctuations in price, whereas nothing is more advantageous to both parties than the reduction of the oscillations of price to a minimum amount. Hence it is, or rather was, that when farmers occupied small holdings with scanty capital, they constantly lost all the benefit of the market from the necessity put upon them of selling in order to realise. When, however, a dealer is possessed of sufficient capital, he is able to tide over a bad time or low rates, and, by waiting for the market, to avoid loss and equalise prices. Again, the existence of abundant capital renders it possible that labour should cooperate. Great undertakings can be carried out only by large capitals, because the benefits of the division of labour, and with them of diminished cost of production, can be attained only by strictly apportioning the kind of work to be done to each labourer who can do it most cheaply.

A third cause of comparative wealth will become operative in the adjustment of the elements of production, and in the readiness with which they can circulate, i.e. be transferred to the centres in which they can be most profitably employed. These elements are labour and capital, and to these may be added,

under certain reservations, public and private credit. Labour may be in excess or defect, not, that is to say, temporarily, but permanently. When it is in excess, we have the state of overpopulation and the evils which can be remedied only by emigration on a vast scale, as in Ireland during the last twenty years. When it is in defect, there may be a great loss of capital. Such a loss occurred in the first colonisation of Western Australia, when it went under the name of the Swan River settlement. Here a vast amount of capital was exported, but in consequence of the fact that labour was deficient, and that no pains were taken by any municipal regulations to prevent the labour then present from being dispersed, the colony came utterly to ruin. At all times, indeed, labour moves more slowly than any other economical value, and therefore no legislative impediment should be put in its way. But in this country the motive energies of labour have been inconceivably crippled by the law of parochial settlement. Had it not been that the industry of the north of England always demanded more labour than was supplied, and that therefore immigration has gone on towards the manufacturing districts, unimpeded by alarms as to the contingency of pauperism, the degradation of the English labourer would have been complete. As it is, the manufacturing districts have formed a sort of half-way house to America and the colonies, and a means of relieving to some extent the excess of population. And though it will be long before the habitual helplessness of the agricultural labourer induced by the system of settlement is removed, there is reason to think that since the system is all but expunged from the statute book, labour will circulate with greater rapidity than before. [PAUPERISM.]

An excess or defect of capital may characterise the economical condition of a country. When capital is in excess, the problematical stationary state of economists is induced. We say problematical, for though there is no doubt that such a state of things marked the Dutch trade of the last century, the causes are manifestly to be found in the utter defiance of common sense which disfigured the commercial policy of Holland. In order to maintain prices, the Dutch curtailed the supply of such tropical products as were derived from their possessions. But they could not limit the competitors for a share in the profits of the business which they carried on, and they could not wholly prevent a trade carried on outside their monopoly. As a consequence, profits sank to a very low rate, so low indeed that capital could hardly be accumulated in proportion to expenditure. But when such notions are exploded, and it is understood that a low rate of profit on each sale may mean an aggregate high rate of profit by the extension of demand among consumers, it does not seem likely that such a state of things is near enough for anyone to find it worth speculating about.

Credit is not wealth, but a power by which wealth may be utilised. It is a moral force, operating in the fullest way and with the best results when it is justly accorded, by the fact that it enables the fullest use to be made of accumulations. The world will always possess borrowers and lenders. The more of both classes, the more trustworthy are the former. Again, it is impossible that all transactions, except at a great waste of power, should be simultaneously liquidated, and thus trade is impossible or scanty without mutual credit. This credit may be public or private. The credit of a government is the means by which it can negotiate loans, and depends entirely on the responsibility to which the executive is liable, and the fulness with which it is exposed to public opinion. Private credit is that of traders, and may be, indeed commonly is, far higher than that of administrations. Now as credit is measured by the rate of interest or discount, and as profit is the excess of price over the cost of production plus the rate of interest, it will be clear that deficient credit is an absolute bar to production, or at any rate to comparative profit.

A fourth cause of comparative wealth is found in the habitual standard of comfort which labourers enjoy, or, as Mr. Jones calls it, the habit of secondary wants. Demand is the stimulant to industry, other conditions being fulfilled. But demand will not be operative among the mass of the community unless they provide to themselves some standard of living from which they will not voluntarily depart. But a high standard of comfort indicates a progressive state, and a large margin of voluntary expenditure enjoyed by the working classes is at once evidence of their industrial capacity and a pledge of their procuring an increasing share in the distribution of profits. [POPULATION.]

A fifth cause lies in the spread of moral and intellectual education. The existence of a criminal population implies the subsistence of a certain class by a violent abstraction from property and profits. Not only is crime a loss proportionate to the injury inflicted, but it leads to insecurity, entails large expense in protection to persons and property, with the charges of legal procedure, and the maintenance of a large class of professional advocates. So in a less degree, but from similar causes, trades have been lost by the want of trustworthy persons, or by the frauds of producers; and the accumulation of capital is constantly checked by the want of safe objects in which the investment of profits may be made, and by the risk of peculation, embezzlement, or criminal negligence. So in common mechanical trades, overlookers are necessary in order to secure the employers of labour against fraud, and the expense of the product is enhanced by the need of watching against dishonesty. Again, the ignorance of fundamental economical laws is a serious hindrance to the productiveness of labour. The effect of imprudent marriages, of the consequent charge on the labour fund by the maintenance of the poor out of the rates, and of frequent strikes,

are illustrations of how ignorant working men are of the conditions which surround their calling in common with that of other men. At present there can be little doubt, that from one-half to one-third of the effectiveness of labour is lost by the regulations imposed out of apparent self-interest on the labour of operatives. It is certain that by far the greater part of the loss falls on themselves, in the deficiency of their habitations, and in the high rent which they pay for scanty accommodation. There can be, in short, only one legitimate way by which wages can be raised, by a diminution of labour itself, and by the search after a new market; and any indirect means by which attempts are made to raise the money rate are certainly unfair, and as certainly nugatory in the end. No one can object to any man setting a price on his labour and declining to work except at that price; but if his action under the circumstances leads him to coerce his fellow workmen, or to exact hard terms from the consumer of the commodity which he supplies, he will be sure to find that he will be among the first to suffer. Intellectual education is also a powerful cause of material progress, not only because it induces desires for a higher standard of comfort, but because it gives that capacity for adaptation and facility in invention and accommodation to circumstances, which makes labour more easily circulate, and find out its best market. The Germans, who are all subjected to primary education, are the most thriving among the American settlers.

Lastly, whatever extends the productive age of labour, is a means of increasing wealth. All the maintenance of children who die before the working age is a loss to the community, and such conditions as diminish human life when it becomes productive are of a similar character. Hence those sanitary regulations which make life longer, obviate the interruptions of sickness, and generally promote the health of the people, have a marked effect, other causes combining, on industrial prosperity. The progress which has been made in physiological enquiry, and the police precautions taken to insure health, are as powerful contributories to public wealth as any other cause. Ill-nurtured, ill-fed, ill-clothed, ill-trained labour is always dear, however nominal may be the rate at which it is remunerated.

It has not been possible in this slight sketch to give more than the leading features of a progressive state of wealth, or to do anything beyond pointing out the agencies, present and to come, which are the necessary causes of material prosperity. Some of the remaining points will be treated of in separate articles, in which it will be necessary to refer the reader to the best and most popular works on political economy. Among these, in addition to the works already named, although the writer cannot invariably agree with the conclusions arrived at, may be mentioned the useful and comprehensive manual of Mr. Henry Fawcett, the professor of political economy in the university of Cambridge; the works of Bastiat, some of which have been translated into English; and the essays edited by Dean Dawes.

Politics. Political science is that which treats of the theory and practice of government, and the subjects which it comprises have been arranged under the following heads: 1. Natural law; 2. Abstract politics, i.e. the object of a state, and the relations between it and individual citizens; 3. Political economy; 4. The science of police, or municipal regulation; 5. Practical politics, or the conduct of the immediate public affairs of a state; 6. History of politics; 7. History of the European system of states, being the only system in which the modern art of politics has received a practical development; 8. Statistics; 9. Positive law relating to state affairs, commonly called constitutional law; 10. Practical law of nations; 11. Diplomacy; 12. The technical science of politics, an acquaintance with the forms and style of public business in different countries. The ancient Greek writers treated the science of politics uniformly with reference to an imaginary perfect state, the constitution of which each philosopher propounded according to his own speculative views, and then proceeded to show in what respects existing governments differed from this ideal standard, together with the causes of these variations.

Poll. In Politics. [PARLIAMENT.]

Poll-tax (Dutch bol, *the crown of the head*). A tax levied on all members of the community, the very poorest excepted. These taxes have never been popular in this country, perhaps in consequence of the real or supposed connection of the great insurrection of the villains in 1381, with the imposition of such a levy. A poll-tax, however, had been enacted two years before the date of the insurrection, as well as in that year, the rates being graduated according to the rank and supposed wealth of the various persons assessed, and the tax being therefore fair in its incidence.

The hearth-money of the reign of William III. was virtually a poll-tax, and similarly unpopular; and in some of the states composing the American Union, a small tax of this kind is regularly imposed on all alike, as, for instance, a dollar on each adult in Massachusetts.

Pollard. A tree with the head, or poll, cut off at the height of ten or twelve feet from the ground, for the purpose of inducing it to throw out branches all round the section where amputation has taken place. The branches so thrown out are cut off periodically, when they attain the length of eight or ten feet, to be used as fuel, fence wood, or for other rustic purposes. Pollard trees are for the most part found in hedgerows, which they greatly injure by the dense shade produced by their branches on the plants below; and excepting when the round formal heads of the pollards enter into combination with overgrown hedge plants, or with large trees which have not been pollarded, they disfigure the landscape, from the monotony and meanness of their appearance as compared

with that of trees undecapitated and left in their native luxuriance. In the time of Evelyn the term *pollard* appears to have been applied chiefly to trees which were lopped or deprived of their side branches, excepting a few at top, leaving the tree standing like a naked pole. Examples of this kind of pollard are frequent among the hedgerow elms in the neighbourhood of London and in Devonshire. The decapitated tree, now called a *pollard*, was in Evelyn's time called a *dottard*.

Pollen (Lat. *fine flour*). In Botany, the pulverulent substance which fills the cells of the anthers of a plant, consisting of a multitude of hollow cases, of extreme minuteness, filled with a fluid holding very fine molecular matter in suspension. The latter is eventually discharged by the grains of pollen through their hollow tubes, and is supposed to be the spermatic fluid of a plant.

Pollen Tubes. The tubular processes emitted by the pollen when it comes in contact with the stigma of a plant, and which are supposed to conduct the impregnating matter down the style into the ovules through the foramen.

Pollux (Lat.). In Astronomy, one of the twins forming the constellation *Gemini*. [Castor.] Pollux is also the name of a star of the second magnitude in the same constellation.

Pollux. In Mineralogy, a rare mineral. A hydrated silicate of alumina, potash, and soda, remarkable for containing 34 per cent. of cæsium, according to recent analyses of M. F. Pisani. It is massive, colourless, and transparent, and like quartz in appearance. It is found in the granite of Elba associated with Castor.

Pollux. In Mythology. [Polydeukes.]

Polyadelphous (Gr. πολύς, and ἀδελφός, *a brother*). In Botany, this term is applied to flowers which have the stamens united into several distinct sets.

Polyandria (Gr. πολύς, and ἀνήρ, *a man*). The thirteenth class in the Linnæan system. It includes those plants the flowers of which have hypogynous stamens more than twenty in number.

Polyanthes (Gr. πολυανθής, *many-flowered*). A favourite cultivated flower, quite distinct from the Polyanthus. The genus *Polyanthes* belongs to the *Liliaceæ*, and its most familiar species is the Tuberose met with in our hothouses, and prized on account of the fragrance of its flowers. It is a perennial, with bulbtuberous stems, throwing up from the heart of leaves a tall flowering scape, which supports at top a short many-flowered spike of creamy-white highly fragrant flowers, the double forms of which are greatly prized. Large quantities are annually imported from Italy. It is recorded that in sultry evenings, after thunder, when the atmosphere was highly charged with electric fluid, the Tuberose has been observed to dart small sparks of lucid flame from such of its flowers as were fading.

Polyanthus (Gr. πολυανθής). An umbellate-flowered variety of the Primrose, *Primula vulgaris*, cultivated in gardens for its variously coloured gay-looking flowers.

Polyarchy (Gr. πολυαρχία). A word sometimes used by political writers in a sense opposed to monarchy: the government of many, whether a privileged class (aristocracy) or the people at large (democracy).

Polyargite. An altered form of Anorthite from Sweden.

Polybasite (Gr. πολύς, *many*, and βάσις, *base*). A sulphantimonite of silver, in which part of the silver is replaced by copper, and part of the antimony by arsenic. It occurs in short, tabular, six-sided prisms, which are striated parallel to their bases, opaque, and of an iron-black colour by reflected light, but cherry-red in thin slices when viewed by transmitted light. It is found in the mines of Durango in Mexico, Freiberg in Saxony, Schemnitz in Hungary, and Przibram in Bohemia. It has its name from the large quantity of silver present, compared with the other sulphides of that metal.

Polychrest (Gr. πολύχρηστος). A term applied by the old chemists to certain preparations which they regarded as possessed of multifarious virtues. *Polychrest salt* was the sulphate of potash.

Polychroilite (Gr. πολύς, *many*, χροιά, *colour*, and λίθος, *stone*). A silicate of alumina, with peroxide of iron and magnesia, from Krageröe in Norway.

Polychroite (Gr. πολύς, and χροιά, *colour*). A term applied to the colouring matter of saffron, from the variety of colours which it exhibits when acted upon by various re-agents.

Polychromatic Acid (Gr. πολυχρώματος, *many coloured*). A compound resulting from the action of nitric acid upon aloes. When used as a dye-stuff it yields a variety of colours.

Polychromy (Gr. πολύχρωμος, *many-coloured*). In Architecture and Sculpture, the art of decorating with many colours. It is now generally understood that the Greeks habitually coloured their architecture, the exterior of buildings as well as the interior; but that they also coloured their sculpture is not so generally admitted. That the practice, however, of colouring their statues was established among the Greeks of the most refined period, is quite certain. It is proved by passages in Plato, Pausanias, Lucian, Plutarch and other writers. Marble statues were coloured in encaustic, and statue painting was a distinct profession. The naked flesh itself was not commonly painted, but was stained with an encaustic varnish; the colouring was apparently generally confined to the hair, eyes, lips, the drapery, and the ornaments in general; sometimes the hair was gilded, and the eyes were not unfrequently of glass, with eyelashes of copper gilt. The celebrated Nicias was an ἀγαλμάτων ἐγκαυστής, or statue painter, in his youth: he coloured some of the statues of Praxiteles. It is to this practice that Pliny refers when he speaks of the *circumlitio* of Nicias as applied to the statues of Praxiteles.

(Wornum, *Epochs of Painting &c.* p. 103 ff.) The acrolithic and CHRYSELEPHANTINE sculpture was virtually polychromic. (Kugler, *Ueber die Polychromie &c.*; Semper, *Ueber bemalte Architectur und Plastik bei den Alten*; and Quatremère de Quincy, *Le Jupiter Olympien.*)

Polycotyledonous (Gr. πολύς, and κοτυληδών, *a seed lobe*). In Botany, this term is applied to those embryos which have more than two cotyledons.

Polycrase (Gr. πολύς, and κρᾶσις, *mixture*). A rare mineral occurring at Hitteroe in Norway, in black six-sided tables, which are of a brownish colour in thin splinters. It contains titanic and columbic acids, zirconia, yttria, peroxide of iron, protoxide of uranium, protoxide of cerium, a small quantity of alumina and traces of lime and magnesia. The name has reference to the many substances which enter into its composition.

Polydectes. [PERSEUS.]

Polydegmon (Gr. πολυδέγμων, *receiving many*). In Greek Mythology, a name given to Hades. [PERSEPHONÊ.] Another form of the name is Polydectes, the persecutor of Danaê and of her son PERSEUS.

Polydeukes (Gr. Πολυδεύκης). In Mythology, one of the Dioscuri (Διόσκουροι, *sons of Zeus*), the other being Castor. Of the birth and home of these heroes the legends give very contradictory accounts. In the *Odyssey* (xi. 298) they are sons of Tyndareus and Leda, and therefore brothers of Helen. [PARIS.] According to another tale, they with their sister were all children of Zeus, and sprang from the same egg. Another myth calls Polydeukes and Helen only the children of Zeus, and makes Polydeukes immortal, Castor, as son of Tyndareus, being subject to age and death like other mortals. The second part of the name Polydeukes is found in DEUCALION, and is probably another form of λευκός, *light*, or *brilliant*. The Dioscuri take part in the expedition of the Argonauts [MEDEA; MYSTERIES]; but according to the *Iliad* they had died or disappeared from the earth before the Trojan war. The name of Castor was associated especially with skill in the taming and management of horses, that of Pollux, with boxing. In the *Odyssey* (xi. 301) they are represented as coming to life on alternate days and enjoying an honour equal to that of the gods. [NEMESIS.]

Polydipsia (Gr. πολύς, *much*, and δίψα, *thirst*). Excessive thirst. This name has been given to a form of diabetes known as *diabetes insipidus.* It is characterised by the discharge of large quantities of urine of low specific gravity, and is a most dangerous malady. Pathologists incline to regard it as the result of nervous lesion.

Polygala (Gr. πολύς, and γάλα, *milk*). The typical genus of *Polygalaceæ*, very widely distributed and exceedingly various in character. A few species, as *P. cordifolia* and its allies, are handsome greenhouse shrubs. The most important, however, is *P. Senega*, the root of which is used as a stimulant diaphoretic and expectorant, especially in cases of chronic bronchitis. The active properties appear to depend upon an acid substance found principally in the rind of the root, and called *polygalic* acid, or sometimes *senegin*. This root was introduced into medical practice by Dr. Tennant, a Scotch physician residing in Pennsylvania, as a remedy for snake-bites. Several other species are described as having similar virtues. They seem to act as stimulant emetics, purgatives, and diaphoretics, and relieve the embarrassed breathing which occurs in such cases.

Polygalaceæ (Polygala, one of the genera). A natural order of irregular polypetalous Exogens of the Sapindal alliance, possessing tonic, astringent, and nephritic properties. The order is known by its complete irregular unsymmetrical flowers, its naked petals, its one-celled anthers opening by pores, and its carunculate seeds. The species are also sometimes cultivated for the sake of their beautiful flowers. They usually inhabit temperate climates, and are common at the Cape of Good Hope. Rhatany root, a powerful astringent, belongs to *Krameria*, a genus of this order.

Polygamous. In Botany, among grasses this term signifies that when one of the two flowers of which a spikelet consists is unisexual, the other is hermaphrodite, as in *Spodiopogon*, &c. Among other plants it expresses the presence in the same individual of male, female, and hermaphrodite flowers.

Polygamy (Gr. πολυγαμία, from γάμος, *marriage*). The custom of having several wives; a custom apparently common to all nations in remote antiquity, and common now to most of those in which the tie of marriage is recognised, and to which Christianity has not extended. It was admitted under the Mosaic dispensation (Exod. xxi. 10; Deut. xxi. 15); and Selden (*Uxor Hebraica*) has shown its prevalence among the Jews, without mentioning the extraordinary instances of sovereigns, such as David and Solomon. Some have supposed, from such passages as 1 Tim. iii. 2, that it was occasionally practised down to the apostolic age. The severer manners of Western nations seem to have repudiated it. The notion that the Athenian laws allowed of two wives (founded in part on a passage in *Athenæus*, xiii. i.) seems a mistake; but it appears to have been allowed to a citizen, in addition to his lawful wife, herself a citizen, to live in a kind of legitimate concubinage with a female not belonging to that class. Thus, if there is any truth in the story of the two wives of Socrates, his plague, Xanthippe, was the wife by right, while the softer Myrto was a wife only by courtesy. In republican Rome no such license was known; but under the emperors the practice of polygamy seems to have crept in from the East, though repudiated both by the moral sense and civil usages of the people. Valentinian I. legalised it by an edict. But the Christian ecclesiastics of the empire strenuously opposed it; and it gradually disappeared from Christendom after the

fall of the Roman empire. In the East it has continued to prevail. A few bold writers in modern times have raised the defence of polygamy, grounded on an alleged absence of express prohibition. Bernardus Ochinus, a well-known and able but unsteady theologian of the sixteenth century, who belonged by turns to the Roman Catholic and Protestant communions, is among the most remarkable. Lyserus (*Polygamia Triumphatrix*) adopted a still more decided view. The Rev. Mr. Madan, in his *Thelyphthora* (a work which excited extraordinary and very unfavourable sensation on its appearance), asserted that the injunctions in the Epistles to Timothy and Titus, restraining bishops and elders from having more than one wife, meaning one wife at a time, plainly demonstrated the lawfulness of the practice in all others. But a greater number of philosophical writers have sought for a justification of the practice in the East. Voltaire, Montesquieu, and others, defend it on the ground of the rapid decay of female beauty in those regions. Montesquieu also relies on the strange notion, that the number of females in Eastern countries is much greater than that of males. But the supposed fact on which these reasonings rest seems to be altogether imaginary. At all events, the *practice* of polygamy in the East is confined to so few that it can have little direct effect on manners, and none on population. Niebuhr says, that in Arabia the conduct of those who take more than one wife 'is blamed by all other men.' But it seems scarcely to have occurred to most reasoners that while polygamy itself is rare, its recognition is almost always accompanied with the toleration of concubinage by public morality. The man who is not rich enough to take two wives, or who does not choose to encounter the household disturbances which follow such an arrangement, falls entirely in with the public opinion of his class, in taking into his family a recognised concubine to dwell with his lawful spouse. Some curious remarks on the subject of polygamy may be found in Lady Duff Gordon's *Letters from Egypt*, and in the writings of Captain Burton, *Journey to the Great Salt Lake City*, &c. [MORMONISM.]

Polygastria (Gr. πολύς, and γαστήρ, *a stomach*). The name of the most minute and simple class of Infusories and of the whole organic kingdom. The Polygastrians have been characterised as animalcules devoid of spinal marrow, and of vascular and respiratory organs, with many stomachs, of an indefinite form, and androgynous, with spurious locomotive organs of various nature. They are all endowed with an organisation characteristic of the kingdom *Acrita*; and manifest such modifications of internal structure and external form that they could be divided into twenty-two families, of which eleven are naked and eleven clothed in a silicious case. They occur in all parts of the world, and differ according to diversity of climate, region, kind of water, &c. They are invisible to the naked eye; but, by their immense numbers, they can impart a distinct colour to the water in which they swarm, and are one of the causes of the phosphorescence of the sea. They enjoy the most extensive powers of reproduction; and through their faculty of spontaneous *fission*, the individual becomes constant, and, as it were, perpetually renews its youth. By virtue of the imperishability of their external cases the *Polygastria* have formed vast masses of rock, as at Bilin in Bohemia, where a single stratum, extending over a wide area, is no less than fourteen feet thick; and this consists exclusively of the cases of *Bacillaria*, *Gaillonella*, &c., united together without any visible cement. They sometimes so choke up water by their vast numbers as to cause the death of fishes contained therein. They appear never to sleep: they are very tenacious of life, and fall into a kind of torpidity by excess of dryness, heat, or cold. The more minute species are probably often suspended in the air. They act according to external circumstances, seemingly as the higher organised animals do. They are injuriously affected or killed by strong poisons, but can sometimes support great degrees of warmth and cold, and can live with or without light. Their motions are slow. Ehrenberg calculates that the *Monas punctum*, if it were to continue its ordinary rate of motion in a straight line, would traverse one mile of space in five years; while the *Navicula grandis* would require forty years to travel over the same distance. Their movements simulate the phenomena of consciousness and choice, and muscular power is significantly indicated by the strong maxillary apparatus with which many are provided.

Polyglot (Gr. πολύγλωττος, *many-tongued*). A word generally applied to such Bibles as have been printed with the text in various languages. The most ancient instance of this parallel representation of various texts is the work of Origen, known by the name of the *Hexapla*, in imitation of which several similar editions of the Scriptures have been published since the invention of printing. Of these the most important are: 1. *The Complutensian*, or edition of Cardinal Ximenes, printed at Alcalá in Spain, 1515, in four languages, comprehended in six vols. folio. 2. *The Plantin*, Antwerp 1572. 3. *The Polyglot* of De Sacy, Paris 1645. 4. *The English* or Walton's *Polyglot*, London 1657. These contain among them the Hebrew, Chaldee, Syriac, and Samaritan texts, with Latin versions of each; the Septuagint, the Greek of the New Testament, the Italic and the Vulgate; with some of the Hebrew and Chaldee paraphrases, and copious indexes and grammatical illustrations. 5. Hutter's *Polyglot*, Nuremberg 1599, contains twelve languages; the Hebrew, Syriac, Greek, Latin, German, Bohemian, Italian, Spanish, French, English, Danish, and Polish. (Hallam, *Literary History*, iii. 446.)

Polygon (Gr. πολύγωνος). A figure of many angles or corners. In *polygonometry*,

that branch of geometry in which the properties of polygons are investigated, the angular points are conceived to be situated either anywhere in space, when the polygon is termed *skew*; or on the surface of a sphere, when it is termed *spherical*; or in a given plane, which is the most frequently occurring case, and the only one we shall here notice.

The *complete polygon* of n angles has

$$\frac{n(n-1)}{1.2}$$

sides, which are the right lines joining all possible pairs of points. Thus, although a complete *trigon* has only three sides, a complete *tetragon* has six, and so on. [QUADRANGLE.] A complete n-gon comprises $3.4 \ldots (n-1)$ different *simple polygons*, each of which is formed by joining the n points in a *certain order*. Of such simple polygons, however, only those are contemplated in elementary geometry whose unproduced sides do not cut each other, and the latter are themselves divided into two classes; viz. *convex polygons*, the interior angles of which are all less than two right angles, and *concave polygons*, of which one (or more) of the interior angles exceeds two right angles. The angles of the first class are all *salient*, whilst polygons of the second class are distinguished by the possession of one or more *re-entering* angles. Although Euclid considers only convex polygons, the first corollary to his prop. 32, book i. (according to which all the interior angles, together with four right angles, are equal to twice as many right angles as the figure has sides), is also true for concave polygons. His second corollary, however, according to which the sum of all the exterior angles is equal to four right angles, is only true in the case of convex polygons.

Theoretically the simplest way of finding the area of an ordinary polygon is to take the sum of the areas of the triangles into which it may always be divided. Other elegant methods have been given by Gauss, in Schumacher's translation of Carnot's *Géométrie de Position* (Altona 1810), and by L'Huilier, in his *Polygonométrie* (Geneva 1789).

A polygon whose angles and sides are all equal, is termed *regular*. The corners, as well as the sides, of such a polygon are equidistant from one and the same point, the common centre of the inscribed and circumscribed circles. The problem, to inscribe a regular polygon in a circle by means of the ruler and compass alone, is not always solvable. Euclid has shown how to inscribe a regular trigon, tetragon, pentagon, and quindecagon in a circle, and by repeated bisection of sides, his solutions may easily be extended to polygons having 2^m, 3.2^m, 5.2^m or 15.2^m angles, where m is any number whatever. Gauss has shown, too, in his *Disquisitiones Arithmeticæ*, that we may consider as inscriptible all polygons the number of whose sides is equal to the product of some power of 2 by a prime of the form 2^m+1. The first two primes of this form are 3 and 5, corresponding to the values 1 and 2 of m. The value $m=3$ gives the number 9, which is not a prime; to $m=4$ corresponds the prime 17; and the next prime of the series is 257, corresponding to $m=8$. The inscription of the 257-gon has been examined by Richelot in Crelle's *Journal*, vol. ix.; that of the 17-gon has been treated by Gegenbret, in his *Élèments de Trigonométrie*; by Grünert, in Klügel's *Math. Wörterbuch*; by Staudt in Crelle's *Journal*, vol. xxiv.; by Mr. Lowry in Leybourn's *Math. Repository*, vol. iv.; as well as by several others.

Besides the ordinary regular polygons, there are also regular stellated polygons which are formed by drawing, without lifting the pen, diagonals of an ordinary polygon so as always to cut off the same number of sides, the number cut off being prime to the total number. For instance, 1 2 3 4 5 1 being a regular pentagon, 1 3 5 2 4 1 will be a stellated one.

Little need be added with respect to spherical polygons. The area of a convex spherical n-gon is

$$[\Sigma-(n-2)\pi]r^2$$

if Σ denote the sum of its angles and r the radius of the sphere.

POLYGON. In Fortification, a polygon is either *exterior* or *interior*. The exterior polygon is the figure formed by lines connecting the angles of the bastions with one another all round the work; the interior polygon by lines in prolongation of the curtains. [FORTIFICATION.]

Polygon of Forces. In Mechanics, the name given to a theorem, the discovery of which is attributed to Leibnitz. The theorem is this: If any number of forces act upon a point, and a polygon be taken, one of the sides of which is formed by the line representing one of the forces, and the following sides in succession by lines representing the other forces in magnitude, and parallel to their directions, then the line which completes the polygon will represent the resultant of all the forces.

Polygonaceæ (Polygonum, one of the genera). A natural order of herbaceous, rarely shrubby, apetalous hypogynous Exogens, inhabiting the whole world, and referred by Lindley to the Silenal alliance. They are distinguished from most other plants by the cohesion of the scarious stipules into a sheath, technically called an *ocrea* or *boot*, and by their triangular fruit. Sorrel on the one hand, and Rhubarb on the other, represent the general qualities of this order. While the leaves and young shoots are acid and agreeable, the roots are universally nauseous and purgative. *Rumex acetosa* contains pure oxalic acid, and many species of *Polygonum* are used in dyeing. The *Rheum* or Rhubarb, and *Rumex* or Dock, are well-known plants of this order; which is also sometimes remarkably astringent, as in the case of the *Cocoloba uvifera*, or Sea-side Grape of the West Indies, an extract of whose bark forms a kind of KINO.

Polygonal Numbers. In Arithmetic, the successive sums of the terms of an arithmetical

series beginning with unity. They are FIGURATE NUMBERS of the second order.

A very general and remarkable property of polygonal numbers was discovered by Fermat, though it has yet been demonstrated only in respect of the triangular and square numbers. It is this: Every number whatever is the sum of one, two, or three triangular numbers; the sum of one, two, three, or four squares; the sum of one, two, three, four, or five pentagonal numbers; and so on.

Polygram (Gr. πολύς, and γράμμα, *a line*). A figure consisting of many lines or sides. An ordinary polygram is the same as an ordinary POLYGON [which see]. It would be well, however, if the distinction between polygon and polygram were more strictly adhered too. A complete n-gram has $\frac{n(n-1)}{1.2}$ angular points or corners, whilst a complete n-gon has $\frac{n(n-1)}{1.2}$ sides. As an illustration, see QUADRANGLE and QUADRILATERAL.

Polygraph (Gr. πολύς, and γράφω, *I write*). In Bibliography, this term designates a collection of different works either by one or several authors.

Polyhalite (Gr. πολύς, and ἅλς, *salt*). A hydrous sulphate of lime, potash, and magnesia, with muriate of soda, found at Ischl, in Upper Austria, where it occurs in compact fibrous masses of a brick-red or flesh colour, and sometimes colourless.

Polyhedron (Gr. πολύς; ἕδρα, *a base*). In Geometry, a solid bounded by many planes or *faces*. Each face is bounded by three or more right lines or *edges*, and three or more faces by their intersection form a *corner*. The theory of polyhedrons, although studied by the ancients, is still incomplete and defective in many points; we shall merely mention a few of their most elementary and important properties.

If with respect to any sphere, we take the polar plane of every corner of a given polyhedron, we shall obtain a second having as many faces as the first has corners, as many corners as it has faces, and precisely the same number of edges. [POLES AND POLARS.] So that the *principle of duality* holds for all polyhedrons; that is to say, to every polyhedron corresponds its *conjugate*, which has as many n-angled faces as the first has n-angled corners.

If by taking away one face from an *incomplete* or *unclosed* polyhedron which has e edges, c corners, and f faces, we remove n corners, we shall necessarily diminish the number of edges by $n+1$, so that the number $c+f-e$ will remain unaltered by the operation, and consequently also by its repetition. Since this repeated subtraction, however, must ultimately lead to a single face with as many corners as edges, we see that for every unclosed polyhedron $c+f-e=1$. If we unclose any polyhedron, therefore, of E edges, C corners, and F faces, by removing a face, we shall obviously have $C+(F-1)-E=1$; i.e. $C+F=E+2$. This fundamental theorem, according to which *the number of corners, together with the number of faces, of every ordinary polyhedron, exceeds by two the number of its edges*, although known to Descartes, was rediscovered and first published by Euler in the *Nov. Comm. Petrop.* 1752. From it numerous consequences may be deduced. It can be shown, for instance, that there is no polyhedron of seven edges, and that some of the faces of every polyhedron must necessarily be either triangular, quadrangular, or pentagonal; hence also some of its corners must necessarily be triangular, quadrangular, or pentagonal. These are consequently termed the *essential* elements of every polyhedron. It can be shown, too, that there are but five distinct *regular polyhedrons*, or such as have equal regular polygonal faces and corners. In fact, if each face is a regular polygon of n sides, then obviously $2E=nF=mC$, if m be the number of plane angles that meet at every corner. It follows, therefore, from the fundamental relation, that

$$E=\frac{2mn}{2m+2n-mn}.$$

This can only be a whole number in five distinct cases, since neither m nor n can be less than three or greater than five. The name and nature of each of the *five regular polyhedrons*, or, as they are often called, *Platonic bodies*, is given in the following table.

Name	m	n	E	F	C
Tetrahedron or Regular Pyramid	3	3	6	4	4
Hexahedron or Cube	3	4	12	6	8
Octahedron	4	3	12	8	6
Dodecahedron	3	5	30	12	20
Icosahedron	5	3	30	20	12

The hexahedron and octahedron are conjugate, as are also the dodecahedron and the icosahedron. The tetrahedron is manifestly its own conjugate.

Besides the above, there are the *semi-regular polyhedrons* of Archimedes, the corners of which are equal and similar to one another, but formed by regular polygons of different kinds. Pappus (in the fifth book of his *Collections*) and Kepler enumerate thirteen distinct semi-regular polyhedrons. They omit two, however: one is a right prism, whose bases are equal regular polygons of any number of sides, and whose lateral faces are all squares; the other may be formed from the first by conceiving one of the two equal polygons to be first twisted, and each of its corners then joined to two of the other polygons, so that the lateral faces become equilateral triangles.

There are also *stellated regular polyhedrons*. These were first described by Kepler, and have been since studied by Poinsot and others. (*Journal de l'École Polytechnique* 1809, and *Comptes Rendus* 1858–9.) We may mention, lastly, that the theory of polyhedrons has been greatly extended in recent years by the researches of Kirkman, whose memoirs will be found in the *Phil. Trans. of the Royal Society*.

Polyhedron. In Optics. [Polyscope.]

Polyhydrite (Gr. πολύς, and ὕδωρ, *water*). A hydrated silicate of iron from Breitenbrun in Saxony. It is the same as the Hisingerite of Berzelius.

Polyhymnia (Gr. Πολυΰμνια). The muse who presided over lyric poetry. (Hesiod. *Theog.* 78; Hor. *Od.* i. 1.)

Polykrase (Gr. πολύς, and κρᾶσις, *combination*). A rare mineral occurring in black six-sided tables: it contains titanic and tantalic acids, zirconia, yttria, alumina, magnesia, lime, and the oxides of iron, cerium, and uranium. It is found at Hitteröe, in Norway.

Polylite (Gr. πολύς, and λίθος, *stone*). A variety of Pyroxene from Hoboken in New Jersey. The name has reference to the numerous constituents of which it is composed.

Polymignite (Gr. πολύς, and μίγνυμι, *to mix*; from the number of its components). A titanate of Zirconia, which occurs in long thin prismatic crystals with a brilliant submetallic lustre, in the zircon-syenite of Fredericksvärn in Norway.

Polynomial. [Multinomial.]

Polynomial Theorem. [Multinomial Theorem.]

Polyonymy (Gr. πολυωνυμία, *a multitude of names*). The description of the same object under several names. This practice marks one of the necessary stages in the growth of language, and furnishes the great source of Mythology. It is obvious that a common root may be used to describe different objects which agree in some special point: thus, a word denoting brightness might be applied to the morning, a fountain, or the spring-time of the year, which would thus be *homonymous*, or namesakes. But it is also manifest that the same object may be described by several characteristics. The sun may be called the child of the night, the destroyer of darkness [Perseus], the slayer of the dawn [Apollo], the husband of the morning [Eos], or of the dew [Procris]; and thus the sun would be *polyonymous* or many-named, while each name would supply the idea of a separate myth. (Max Müller, *Lectures on Language*, second series, viii.)

Polyoptron. In Optics, a glass through which objects appear multiplied, but diminished. It consists of a lens, one side of which is plane, while in the other are ground several spherical concavities. Each of these concavities becomes a plano-concave lens, through which an object appears diminished; and when there are a number of them together, the object will be seen through each, and thus multiplied.

Polypes (Gr. πολύπους). The name of an extensive group of radiated animals in the system of Cuvier, associated together by the common character of a fleshy body, of a conical or cylindrical form, commonly fixed by one extremity, and with the mouth situated at the opposite end and surrounded by more or less numerous arms or tentacles. Under this external form are masked various grades of organisation, of which three at least have been well defined by recent and minute anatomical researches.

The lowest grade of organisation is manifested by the fresh-water Polype (*Hydra*), and the compound marine corallines (*Sertulariæ*, *Tubulariæ*, &c.). The body here consists of a granular parenchyma, having a contractile power in every part, not requiring a distinct allocation and arrangement of muscular fibres. When it is defended, as in the Corallines, by a polypary, it can be retracted into its cell without being folded upon itself. The oral tentacles are not provided with vibratile cilia; the stomach is not distinct from the parietes of the body. The polypes thus organised have been termed *Dimorphæ* by Ehrenberg; *Hydrozoa* by Owen; and *Nudibrachiata*, or Hydriform Polypes, by A. Farre. In the second group of Polypes the body is distinctly membranous and fibrous, and the stomach forms a separate pouch suspended in its centre. The stomach has but one external orifice, which serves for mouth and vent; but posteriorly it communicates with the main cavity of the body. This is divided into several compartments by vertical partitions passing from the walls of the cavity to those of the stomach; and with the chambers thus formed the tubular arms surrounding the mouth communicate: these arms are not ciliated externally. This group of Polypes has been termed *Anthozoa* by Ehrenberg: it includes the Sea-anemones, Madrepores, Coral-polypes, &c. In the third and highest group of Polypes the parietes of the stomach are not only distinct from those of the body, but are continued into an intestinal tube, which is reflected forward and terminates in a distinct anal aperture near the mouth: the tentacula are provided with vibratile cilia. The Polypes of this division are aggregated or compound, and provided with flexible or calcareous cells: they have been termed *Bryozoa* by Ehrenberg, and *Ciliobrachiata* by Farre. All the groups of Polypes propagate by gemmation, and likewise by ova, which are first developed into ciliated and locomotive gemmules. In some *Ciliobrachiata* the sexes are distinct. The *Acalephæ* of Cuvier belong, metagenetically, to the *Hydrozoa*, while the *Bryozoa* have affinity with the compound *Ascidians*.

Polypetalous (Gr. πολύς, and πέταλον, *a leaf*). In Botany, a term applied to flowers in which the petals are separate, rather than to those in which they are numerous, as the name would seem to imply. It is used as the antithesis to *monopetalous*.

Polyphemus. In Mythology. [Cyclopes.]

Polypodiaceæ (Polypodium, one of the genera). The most comprehensive of the natural orders under which Ferns are arranged, including nearly all the species which are known. It is distinguished mainly by the presence in the spore-cases of an elastic jointed ring which nearly surrounds them, and by the contraction of which they seem to burst open when ripe. [Filices.]

Polyporus (Gr. πολύπορος, *with many pores*). A very extensive genus of Fungi, belonging to the pore-bearing division of that vast order. The pores vary much in size, being sometimes almost invisible to the naked eye. Some of the species are of a brilliant scarlet, others lilac, yellow, orange, &c., but the predominant colours are tints of brown. A few of the species, as *P. ovinus*, afford a grateful food, but in general they are coarse, tough, and indigestible. *P. tuberaster*, which springs from the Fungus Stone [Pietra Fungaja], is esteemed in Italy, and a species is raised from pollard hazels by roasting them gently before the fire and then keeping them properly irrigated. *P. fomentarius* supplies the best Amadou of commerce, though inferior kinds are produced from other species, as *P. igniarius*. *P. officinalis* was once a celebrated drug, but it is now little used, though still to be obtained in the herb-shops; it grows almost exclusively on Larch. *P. destructor* and some others are the pest of wooden structures, while the spawn of *P. hybridus* is the dry-rot fungus of oak-built ships. *P. betulinus* forms excellent razor-strops.

Polyptychodon (Gr. πολύς; πτυχή, *a fold*; and ὀδούς, *tooth*). A genus of Sauropterygian reptiles (equalling *Pliosaurus* in size), in which the teeth have a strong conical crown with a subcircular transverse section, the longitudinal ridges of the enamel being set close all round the crown, whence the name of the genus; such teeth may be distinguished from the teeth of *Mosasaurus* or *Pliosaurus* by the absence of the smooth, almost flattened faces of the crown, which surface, in those genera, is divided by two longitudinal ridges from the rest of the crown. The teeth are implanted in distinct sockets, as in *Plesiosaurus*.

Polypus (Gr. πολύπους, *many-footed*). In Surgery, a fleshy tumour, which is occasionally formed in the nostrils: the same term is also applied to a fleshy tumour of the uterus.

Polysarkia (Gr. πολυσαρκία). Corpulency. [Obesity.]

Polyscope (Gr. πολύσκοπος, from σκοπέω, *I look*). In Optics, a lens plane on one side and convex on the other; the convex side being formed of several plane surfaces, or *facettes*, so that an object seen through it appears multiplied. The reason of the multiplication of the image is this: When the opposite sides of a thick piece of glass are not parallel, an object seen through it appears out of its true place on account of the refraction; consequently, if a lens is ground so that portions of its convex surface are differently inclined to its plane side, the object will appear in different places at the same time. The polyscope may be used to collect the images of several dispersed objects into a single point, or to collect parts of the same object represented in different places, so as to form a single image. The instrument is a mere toy, and used only for the purpose of amusement.

Polyspaston (Gr. πολύσπαστος, *drawn by many cords*). A term used by some of the old writers on Mechanics to denote an assemblage of pulleys for raising heavy weights.

Polysphaerite (Gr. πολύς, and σφαῖρα, *a sphere*; from its occurrence in roundish masses). A variety of Brown Lead-ore [Pyromorphite] containing phosphate of lime, and a certain quantity of fluoride of calcium. It is of a brown or yellow colour, slightly darker than Pyromorphite, and has a radiated structure internally. It is found near Freiburg in Saxony.

Polystyle (Gr. πολύστυλος, *many-columned*). In Architecture, an edifice in which there are a great number of columns.

Polytechnic School (Gr. πολύτεχνος, from πολύς, and τέχνη, *art*). This establishment was founded in 1794, at Paris, by a decree of the National Convention. Its object is to instruct youth in the mathematical, physical, and chemical sciences. Napoleon, who introduced various modifications into its constitution, gave a military turn to its discipline. It prepares pupils for the artillery service, and civil and military engineering. The number of students is about 350. Youths selected by competitive examination are admitted between the age of sixteen and twenty, or, if in the army, twenty-five, and the course of study lasts two years. It is now regulated by a series of laws passed from 1852 to 1856. In the lists of its professors have been included the illustrious names of Lagrange, La Place, Monge, Berthollet, &c.; and from the ranks of its pupils have proceeded, almost without exception, all the mathematicians and philosophers of France who have attained to eminence during the last half-century.

Polytelite (Gr. πολυτελής, *valuable*). A name for the varieties of Grey Copper-ore which contain silver and quicksilver.

Polythalamaceans (Gr. πολύς, and θάλαμος, *a chamber*). A name applied by De Blainville to an order of Cephalopods, including those which have many-chambered shells. Like all divisions founded merely on external or dermal characters, it contains animals of different degrees of organisation, which cannot be grouped together in the same order in a natural system. Thus *Spirula* and *Belemnites*, for example, are joined with *Ammonites* and *Nautilus*. [Tetrabranchiates.]

Polytheism (Gr. πολύς, and θεός). A belief in many gods, in contradistinction to Monotheism, or the belief in one God. In the absence of historical documents, the evidence of language alone can furnish grounds for definite conclusions on the origin and growth of polytheism. That evidence shows that human thought had already passed through several stages, before the idea of God was embraced by the mind [Language]; but other influences were simultaneously at work, which could not fail to modify that idea. Ignorant of the nature of his own life, and knowing nothing of the nature, origin, and properties of other objects, man could only attribute vaguely to all visible things the same kind of existence as that which belonged to himself. This existence involved

simply the notion of consciousness, for the distinction between consciousness and personality was of later growth. Thus the sun, moon, and stars, would all be living beings; and their influence, in the lack of any idea of a natural order, would be seen in the working of the material world, and in all the accidents of human life. Their action would appear either beneficent or malign; and hence these beings would be invested each with their special character. As being beyond human control, and as affecting the condition of men, they would be loved or feared; and with the growth of the idea that they might be propitiated or appeased, the system of polytheism would be complete. But as long as the names applied to the sun or other objects were understood in their original sense as names for those objects, the number of the deities would be but small. When, as a consequence of dispersion, the meaning of these names was either in part or wholly forgotten, all the words which had described some visible object became a name for an independent being. [POLYONYMY.] The sun as the destroyer of night became PERSEUS; as the lord of light, Phœbus; as the king of day, Kephalos (Cephalus); as sinking to sleep, ENDYMION. The same process went on with all other names, and the result was an infinite multiplication of mythical beings; or, as objects of worship, gods. This developement may be distinctly traced in the fundamental Brahmanic and Zoroastrian myths. In the former, Indra is the sun-god who fights with and conquers his adversary VRITRA, the dark power of night; but the introduction of an ethical sentiment is manifest even in Vedic hymns which speak of Vritra as the enemy of man. On the Iranian soil this moral element altogether excluded the physical; and Vritra became Ahriman, who is engaged in an everlasting struggle with ORMUZD. Thus the great principle of Zoroastrian religion [DUALISM] is no suggestion of human experience or philosophical reflection, but an inevitable result of phrases employed to denote the phenomena of day and night. But although dualism is essentially polytheistic, the two great contending powers remained rather conceptions of the mind than beings of a recognised shape and form. The anthropomorphic tendency would show itself chiefly in less speculative races, and hence would be specially powerful among the Greeks, for whom the king of Olympus and the lord of light became beings of the same form and of the same passions with himself.

The worship of animals has been traced by many to a supposed universal worship of nature. Of this worship the episode of the cattle of Helios, in the *Odyssey* (xii.), is taken by many as furnishing some evidence. (Gladstone, *Homer and the Homeric Age*, ii. 412; Dasent, *Popular Tales from the Norse*, Introduction, xix.; Max Müller, *Comparative Mythology*, 53, 81; Cox, *Tales from Greek Mythology*, 118; *Gods and Heroes*, 68.) But although in Egypt some animals may have been regarded with special veneration, we have no proof of any such idolatry among the Greek or other tribes of the Aryan races. But their mythology supplies abundant illustrations of the way in which such a worship might be suggested. In the Vedic hymns, Indra has his cattle, which are daily driven to their pastures in the fields of the sky; his chariot is drawn by a bull, the same bull which bears EUROPA across the sea. Indra, again, has his horses, the Harits, which by the Jews (2 Kings xxiii. 11), as by other nations, were worshipped in that form, but which in the hands of the Greeks were transformed into the beautiful CHARITES. The animal worship thus suggested might be indefinitely extended, while it might also be degraded into the fetichism which imputes a virtue to inanimate and inorganic matter. The same process of developement would be seen in the idea of sacrifice, and the presentation of simple gifts would be followed by the surrender of the most costly treasures or the most precious life. In the early Vedic religion the horse, sacred to the sun, is also sacrificed to him; and the phrases which represented the death of the solar brides as following close on that of their lord, issued in the practice of SUTTEE.

But all these developements, although in the minds of the multitude they might almost extinguish a monotheistic belief, would not necessarily obscure it for men of deep and earnest thought. The Zeus to whom Achilleus prays in time of real trouble is not the Zeus who recounts the number of his earthly loves, but the Zeus to whom Æschylus appeals as incomprehensible yet perfectly just and righteous, and of whom Sophocles speaks as the father of the unfailing laws of purity and truth. In other words, polytheism began not with a conviction or belief, but from the necessities of human language, and as such it obtained a power over men proportionate to the degree in which they submitted themselves to the tyranny of words, and regarded names as something more than arbitrary titles attached to outward objects for the common purposes of life.

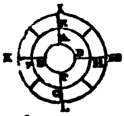
The theory of polytheism has been discussed in such works as Stillingfleet's *Origines Sacræ*; Kames, *Sketches of the History of Man*; Cudworth's *Intellectual System*; Vossius, *De Origine Idololatriæ*; but these writers had not before them that evidence on the earliest phases of human thought which has been more recently furnished by the results of philological science.

Polyxene (Gr. πολύξενος, from πολύς, and ξένος, *a stranger*). A name given by Hausmann to the ore of Platinum, as indicating the many new metals which are associated with it.

Polyzoa (Gr. πολύς, and ζῶον, *animal*). A class of compound animals resembling the Sertularians in their organs of support, but in their internal organisation approaching nearly to the compound Ascidians. The term is synonymous with the *Bryozoa* of Ehrenberg, to which the most extended currency is given.

Polyzonal Lens (Gr. πολύς; ζώνη, *zone*). The name given by Sir David Brewster to a burning lens constructed of several zones or

rings, each of which may be again composed of separate segments. In the annexed figure, A B C D is a central lens formed of one piece



of glass; E F G H is a middle ring, or zone, composed of four separate pieces; I K L M is another ring composed of eight segments, and surrounding the former. The number of zones, and of parts in each, may be as great or as small as we please.

This method of forming lenses is attended with several important advantages. The difficulty of procuring flint glass of sufficient purity to render it fit for the construction of a solid lens of large dimensions is removed, and the expense greatly diminished. If impurity exist in any of the spherical segments, or if an accident happen to any of them, it can easily be replaced. Another advantage attending the construction is, that it enables us to correct, very nearly, the spherical aberration, by making the foci of each zone coincide. Lenses of this kind are now made in great numbers by Messrs. Chance of Birmingham, and are extensively used both in French and English lighthouses.

Pomaceæ (Lat. pomum, *an apple*). That division of the natural order *Rosaceæ* to which the Apple, Pear, Quince, and Medlar belong. It differs from *Rosaceæ* proper in having an inferior ovary.

Pomegranate (Lat. malum granatum, so called from being full of grains). The fruit of the *Punica Granatum*, the pulp of which is acid and the rind highly astringent. The dried flowers, which are also astringent, were formerly used in medicine, under the name of Balaustine flowers.

Pomelloes. The name under which the smaller sized specimens of Shaddock, also designated Forbidden Fruit, are often sold in this country.

Pomœrium (Lat.). In Roman Antiquities, a space of ground, both within and without the walls of a city, kept free from buildings and consecrated by a religious ceremony. (See a memoir of D'Anville on the extent of ancient Rome, *Mém. de l'Acad. des Inscr.* vol. xxi. p. 206; and Dyer, *History of the City of Rome.*) When it was found necessary to extend the limits of any city, a new *pomœrium* was formed, and the former one desecrated.

Pomona. The Italian goddess of fruit-trees. At Rome the flamen pomonalis sacrificed to her every year for the preservation of the fruit. For the story of Pomona and Vertumnus, see Ovid, *Met.* xiv. 623. The name is derived from poma, *fruits*.

Pompholyx (Gr. πομφόλυξ, *a bubble*). An alchemical term for oxide of zinc.

Pompholyx. In Medicine, a vesicular eruption upon the skin.

Pompoleon. One of the names for the Shaddock, and in this country especially applied to the large-sized specimens. It is called Pampelmouse by the French.

Pomum Adami (Lat. *Adam's apple*). The protuberance in front of the neck formed by the thyroid cartilage and gland is so called.

Pond. An artificial excavation in the soil, or a natural hollow dammed up for the purpose of detaining water, generally made in fields in order to supply drink to pasturing animals. The essential difference between a pond and a lake is, that the former is artificial, the water being often ponded, or impounded, by a bank of earth thrown across a natural gutter, hollow, or bourne containing a stream. In Gloucestershire, Kent, and other counties where the soil does not abound in springs, the formation of ponds in the fields is as essential to the business of farming as the building of farm offices. In Berkshire and generally on the chalk downs impervious basins termed *dewponds* are made for the collection of rain-water for the use of sheep. And in dry countries where no springs exist, and where the supply of water is dependent very much on the collection of surface runnels, the formation of ponds connected with the land drainage of the neighbourhood has become a matter of great importance for the use of villages and hamlets. A pond in a garden, when of a round form, is termed a *basin*; and when of some length, with parallel sides, a *canal*.

Pone (Lat.). In Law, a writ which lay to remove actions out of the old common law courts of inferior jurisdiction, such as the Hundred Court, &c., into the superior courts at Westminster. It has fallen into disuse together with the jurisdictions which it was intended to control.

Pongamia (Malabar, pongam). *P. glabra*, an Indian tree, yields from its seeds an oil called Kurunj or Poonga oil, which is much used for mixing with lamp oil. It becomes solid in a temperature below 60° Fahr. The tree belongs to the great Leguminous family.

Pongo. This term was used to define the large adult form of the Orang-outan (*Pithecus satyrus*), which was supposed even in the time of Cuvier to be a distinct species; the term *pongo*, borrowed from Africa, being applied to denote the great anthropoid ape of the Malay Archipelago.

Pons Varolii. The bridge of Varolius An arched eminence of the medulla oblongata, formed by the crura of the cerebellum becoming flattened, and passing over the crura of the cerebrum.

Pont Volant (Fr.). [Bridges, Military.]

Pontee. In Glass Manufacture, an iron instrument by which the hot glass is taken out of the glass-pot.

Pontia (Gr. *of the sea*). A genus of butterflies, of which the common white or cabbage butterfly (*Pontia brassicæ*) is a well-known native species.

Pontifex (Lat.). The highest Roman sacerdotal title. Numa is said to have instituted four pontifices, chosen from the patricians; to which were added, long afterwards, four plebeians. Sylla increased their number to fifteen

The college was divided into two classes, distinguished by the epithets *majores* and *minores*; but it is not certain whether this difference of title marked out the patricians from the plebeians, or the more ancient members from the seven added by Sylla. The pontifices judged in all causes relating to sacred things, and inspected the conduct of the inferior priests. They were a self-elected body down to the latter ages of the republic, when the power of election was sometimes held by the people. It was finally vested in the emperors, who added as many to their numbers as they thought fit. The chief of the pontifices was called the *pontifex maximus*, and was always created by the people, being generally chosen from those who had borne the first offices in the state. His station was one of great dignity and power, as he not only had supreme authority in religious matters, but, in consequence of the close connection between the civil government and religion of Rome, exercised considerable political influence. The title of pontifex maximus being for life, Augustus never assumed it till the death of Lepidus, after which it was always held by himself and his successors to the time of Theodosius. The insignia consisted of the toga prætexta, and a conical woollen cap with a tassel (*galerus*). (*Mém. de l'Acad. des Inscr.* vols. xii. xv. xxiv. xxxvii.) From this word the title of pontiff in modern Europe is derived. *Supreme pontiff* is a common style of the pope.

Pontoons (Fr. ponton; Lat. pons, *a bridge*). A Military term, denoting portable floating vessels, forming the supporting part of the bridge equipment of an army. The Continental pontoons are of a flat-bottomed boat shape, and made of sheet-iron or wood. Our service pontoon is of tin, cylindrical, with hemispherical ends: the large one is 22 feet 3 inches long, and 2 feet 8 inches in diameter; the small one 14 feet 9 inches long, and 1 foot 7 inches in diameter.

Pony (Mr. Wedgwood connects this word with the Polish konik, the diminutive of kon, *a horse*, as the English poll answers to the Old Norse kollr, *the head*: *Dictionary of English Etymology*). The small variety of horse which is found in the northern regions of Europe. The ponies of Norway occasionally possess streaks on the hinder legs, like the quagga of Southern Africa.

Poonahlite. A variety of Scolecite occurring in slender rhombic prisms and radiating fibrous masses, resembling Needlestone. It is found at Poonah in Hindustan, where it forms large white kidney-form masses, with a pearly lustre, in amygdaloid.

Poop (Fr. poupe, Lat. puppis, *a ship*). A partial deck extending from about the mizen mast close aft, above the complete deck of the vessel. It is rapidly disappearing from modern ships, as a useless cause of leeway and a mark for an enemy's shot. A sea coming over the stern is said to *poop* the vessel.

In the vessels of the ancient Greeks and Romans, the highest part of the poop had a fan-shaped ornament, called by the former ἄφλαστον, and by the latter *aplustre*, which rose over the head of the steersman and served to protect him from wind and rain. On the column of Trajan a lamp is suspended from or before the helmsman. The aplustre was the ornament corresponding to the acrostolium which decorated the prow.

Poor Laws, England. The leading statute on this subject is that of Queen Elizabeth, 43 Eliz. c. 2, 'out of which' (says Dr. Burn) 'have arisen more litigation, and a greater amount of revenue, with consequences more extensive and more serious in their aspect, than ever were identified with any other Act of Parliament or system of legislation whatever.' Under this statute and those which followed grew up the system under which every *poor* person was entitled to relief from that parish in which he possessed a Settlement. The great abuses to which this law ultimately led are now matter of history. It was in order to reform them that the Poor Law Amendment Act of 1833 was passed (4 & 5 Wm. IV. c. 76), which is now (though amended by many subsequent statutes) the governing law. The administration of parochial funds was placed under the superintendence of the central board of poor law commissioners. The parishes were consolidated into unions, each administered by a board of guardians, partly elective and partly ex officio. The right of relief was maintained; but the mode of administering it was left under the control of the guardians, subject to the general rules of the poor law board. Several kinds of *settlement* known to the old and complicated law having been abolished, it can now be obtained only: (1) By birth, which is the primâ facie settlement of every one. (2) By parentage; or (3) by marriage; all legitimate children taking the last settlement of the father, and, after his death, of the mother, until *emancipation* (by full age, marriage, &c.), and illegitimate of the mother until sixteen. A woman also acquires her husband's settlement by marriage. (4) By renting a tenement under certain conditions. (5) By apprenticeship. (6) By holding an estate. (7) By payment of public taxes. A poor person also, though not acquiring a settlement, becomes *irremovable* from his place of abode after a certain period of residence. By the Union Chargeability Act of 1865 the cost of the relief of the poor has been thrown on the unions instead of the parishes, as formerly; and questions arising on the law of settlement may be expected to be less frequent than heretofore.

Poor Laws, Ireland. Until the present reign, the poor in Ireland had no legal right to relief; while the system of voluntary assessment, so extensively established in Scotland, hardly existed. In the first year of Victoria the general system of the English poor law was introduced; and by 10 & 11 Vict. c. 90, a board of commissioners for administering the law for relief of the poor in Ireland is established, distinct from that of England.

Poor Laws, Scotland. The Poor Law Amendment Act of Scotland was introduced in 1845 (8 & 9 Vict. c. 83). It establishes a *board of supervision* of ten members (one paid), with power to make rules and regulations; *burghal parishes*, or combinations of parishes with boards of *managers of the poor*, with power to raise funds by compulsory assessment; and gives the *destitute poor* a right of relief in the parish to which they *belong*, the settlement being obtained by reference. Prior to this statute, the relief of the poor was effected by voluntary assessment: and in 1854, 194 parishes still retained this system, while 689 had adopted the *compulsory*.

Poor Rates. [PAUPERISM.]

Pope (Lat. papa). This word, signifying father, was in earlier times applied indiscriminately to all bishops and presbyters; but in the Western church the term has long been confined to the bishop of Rome, who is also designated by Roman Catholics as the Holy Father. In the Greek church it is still the title of all priests. [PAPACY.]

Poplar (Fr. peuplier, Lat. populus). The common name for the trees of the genus *Populus*. These trees are of rapid growth, and consequently their timber is soft, light, and of a loose texture; they are remarkable for a greater or less amount of tremulous motion in the leaves, occasioned by the length and slenderness of the leafstalk, which, instead of being flattened horizontally, or in the same plane with the leaf, as is the case with the generality of trees, are compressed vertically, so that the plane of the leaf and that of the stalk form a right angle with each other. The Lombardy Poplar, *P. fastigiata*, is the formal cypress-shaped tree with perpendicular slender branches common in suburban gardens, but scarcely ornamental except when its taper-head rises above a mass of round-headed trees and breaks or relieves a too continuous horizontal line. Its timber is of little use, except for packing-cases. The Black Italian Poplar, *P. monilifera*, is the fastest-growing of all the species, and sends up a remarkably straight stem. The timber of *P. alba*, the White Poplar or Abele, is of little value; but that of the Grey Poplar, *P. canescens*, a tree of slower growth, is used by the carpenter, turner, and millwright for many purposes. In *P. tremula*, the Aspen, the leaves are especially liable to the tremulous motion peculiar to the family. *P. balsamifera*, the Tacamahac, is remarkable for its fine foliage in early summer, and for the pleasant balsamic odour of its buds and leaves.

Poplin. A kind of fine woven stuff, made of silk and worsted.

Popliteal (Lat. poples, *the ham*). Relating to the posterior part of the knee-joint or *ham*.

Poppets. Timbers used as shores to support the cant-bodies of the bow and stern on the bilgeways preparatory to the launching of a ship.

Poppy (A.-Sax. papig, Lat. papaver). The name commonly applied to the species of PAPAVER. The Opium Poppy, which is the most important species, is *P. somniferum*.

Population. In Political Economy and Statistics, the number of persons occupying the soil of any given country, and maintained by its produce. Enquiries into the amount and distribution of the population in various civilised communities have always a great interest, and are eminently illustrative of important economical principles. The theory of rent, the cost of producing utilities, the laws which govern prices, the circumstances which facilitate or thwart human industry, the stimulants and consequences of emigration, and many other similar subjects, are connected with the facts of population, and the law of its increase.

The population of every settled or ancient country, as contrasted with the population found on such sites as are not yet fully occupied, is the whole number that subsists on its produce. The amount, therefore, and the character of the food habitually required by the people of any given country, is one factor contributing to the total, the rate of production is another, and the power of purchasing and carrying supplies from foreign regions is a third. Whatever may be collected from these elements will, except under peculiar and anomalous circumstances, tend to the aggregate population of the country. Nor does this apply to countries only, for exactly the same causes will be found to govern the growth of cities. When the operation of the causes mentioned above is disturbed or weakened, it is not possible that cities should be large and increasing; but when these causes are fully operative, there is no necessary limit to the aggregation of mankind and the growth of towns. A little further explanation will serve to show the significance of these coefficients.

The first-named cause has not been sufficiently recognised by economists. If the mass of a community demands habitually a high standard of living, and will not, except under temporary pressure, submit to a lower rate, population will not increase in the same ratio as when an inferior or low standard is accepted. For instance, from the earliest recorded times, the staple food of the people of England has been wheaten bread. Now wheat is not only relatively, i.e. by virtue of the demand for it, but absolutely, i.e. by the cost of cultivating it, the dearest of all grain crops. It takes more labour to grow a bushel of wheat than it does to grow a bushel of any other kind of grain. Hence the population, being accustomed to this food, and never voluntarily using any other, cannot become larger than the number which can be maintained on the wheat grown and purchased for the use of food. On the other hand, the Irish subsist generally on potatoes, the Scotch on oatmeal: the one being the cheapest food that can possibly be procured; the other, bulk for bulk, the cheapest kind of grain. Hence there is a tendency among these nations to increase up to the average amount which can be procured of these kinds of food, and, equal amounts

of labour being devoted to cultivation, to multiply in excess of a nation which subsists on wheaten bread, by all the difference between the produce of the one and the produce of the other kind of labour. Nor is this the only consequence. When a dear kind of food is consumed, it is possible on the occurrence of a temporary scarcity to take refuge in an inferior kind; but when a cheap kind is accepted, no such opportunity is afforded. In other words, when a nation lives on wheat, it may suffer dearth, but hardly famine; when a nation lives on potatoes or oats, it is always within danger of famine. [FAMINE.]

By the rate of production is meant the aggregate quantity of food which agricultural science can extract from the soil. In a previous article [LAND] it was stated that this, taking *all* produce into account, is from ten to twelve times more than was procured by the skill and toil of the mediæval agriculturists. It does not seem, however, that the number of persons employed in agriculture has greatly increased, for much of this larger measure of production is due to judicious selection, continuous cultivation, and considerable outlay of capital in permanent improvements. If, however, greater produce is procured at less cost, a continuously increasing number of persons, engaged in other than agricultural pursuits, can be maintained out of the gross produce; and in case every facility be given to production, by the removal of obstacles to the fullest employment of all the powers which exist in the soil or can be induced upon it, it seems likely that the rate of production would be considerably increased. There must be, of course, a limit beyond which production could not be extended; but at present the energies of labour have not nearly reached this limit.

But the whole amount of food needed for the maintenance of labour in densely populated countries is not produced from the soil of these countries, any more than the food of the inhabitants of towns is got by cultivating the land within the boundaries of the town. It is procured by exchange from abroad. The industrial population of a town is engaged in producing articles which may be exchanged advantageously to both parties for the products of agricultural labour, or in importing foreign produce for distribution among the mass of the community. In the same way, if a country is favourably situated for manufacture and trade, it may stand to other parts of the world in the position of a town to the rural region around it; and just in the same way as it would be a grievous hardship to the inhabitants and a serious hindrance to the prosperity of a town, if the municipal magistrates put any impediment in the way of the introduction of food into it, so it is a mischievous policy which puts any difficulty in the way of the importation of food from foreign countries. Many ages, indeed, must elapse before the population of the world becomes so large that its agricultural regions will have no surplus beyond the supply of their own wants, or the cessation of imports from such regions may be induced by the fact that their domestic manufactures will supply them as well as foreign countries do now. Meanwhile, the facilities of transit keep pace with the extension of the area from which supplies are procured. The creation of a railway through a tract of the Western States of the American Union, may be a means by which wheat and other kinds of grain may be exported in quantities sufficient to supply all that may be needed by this country in excess of its own production, although the rate produced by the acre may be very low. It appears, then, that the alarms expressed by many economists as to the narrow margin from which future supplies of food can be obtained, the natural outlets, namely, of rivers, and the sea coast, are not warranted by facts, since we must add to these means of transit the equally important agency of railroads. Furthermore, the cost of freight is diminishing, and seems likely to diminish. Some sanguine persons have anticipated, that in case the supply of coal in this country should fail, it might still be possible to maintain special manufactures by the importation of this necessary from the Pennsylvanian fields; much more, therefore, should we be able to depend upon abundant supplies of wheat and other grain.

There may be, therefore (by the extension of foreign trade, by the manufacture of commodities which command by their cheapness and utility an extended market, by the cultivation of amicable relations between communities, and the abandonment of those jealousies, suspicions, and rivalries, which have been in past times so mischievous to all the interests of mankind, by the adoption of systems of mutual law, and by the practical acknowledgement that for the purposes of mutual benefit all civilised communities have common duties and a common being), an increase of population in certain regions favourably situated for manufacture and commerce, which shall be at once far in excess of any density with which we have yet been acquainted, and far more healthy and satisfactory than even the most favourable instances that have occurred. Much of the anxiety which has been justly expressed as to the social consequences of a redundant population, has been occasioned by the acts of that policy—now, it is to be hoped, exploded—which saw in the growth and prosperity of one community a menace to another, and strove to insulate, or at least to control, instead of harmonising, the commercial action of different states.

The Law of the Increase of Population.—Most governments have encouraged, either by direct privilege or by penalties on celibacy, or at least by social and religious sanctions, the growth of population. In Rome there was a tax on celibates, and a privilege accorded to those who had three children. The dense population of India and China, despite frequent wars and famines, is due in great measure to the religious obligation of marriage. The birth

of a male child is one step to heaven in the Brahmanical catalogue of good works, and a Chinese who has no male offspring is looked on as the victim of a serious misfortune, for he is thus deprived of that posthumous worship which, under the name of honour due to departed ancestors, forms, it would appear, the most fundamental tenet of faith among the Buddhist laity. So, again, the heaviest charge brought against the monks of the pre-Reformation epoch was the fact that by their celibacy they did not contribute to the growth of the people. Marriages were encouraged among the poor under the old law of relief by the allowance system, and until lately a relic of the ancient theory of population was to be found in the exceptional tax levied on bachelors who kept male servants.

Mr. Malthus, in an *Essay on Population*, written and published in 1798, in answer to a work of Mr. Goodwin's entitled *Political Justice*, has the merit of having been the first to discover and expound the principles on which the growth of population is effected, and of having shown that the policy hitherto pursued of encouraging early marriages among the working classes was unwise and dangerous. It must be remembered, in connection with the publication of this theory by Mr. Malthus, that the epoch in which he wrote was one of an exceptional character. The nation was engaged in a war more vast and exhausting than any in which it had ever been engaged. Beyond its own unprecedented military expenditure, it was subsidising its foreign allies. Cash payments were suspended at the banks, and the taxes levied, in utter defiance of all economical maxims, inflicted the maximum loss on the community, at the minimum gain to the state. Nor was there at the time either manufacture or trade by which the scanty supply of home produce could be supplemented from foreign sources.

Mr. Malthus stated his theory in the following formula. Population increases in a geometrical, food in an arithmetical ratio. The children of one generation are the parents of the next, and the number of persons born of each marriage being on an average double or treble the number of the parents, the growth of population would, if unchecked, go on according to the progression of 2, 4, 16, &c. Increased quantities, however, of the necessaries of life can be attained only by increased labour. Thus, were there no external checks, population would soon outrun the means of subsistence, and these checks Mr. Malthus found to be vice, misery, and moral restraint. Stated so nakedly, the theory seems exceedingly repulsive, and it was in fact so unpopular, that the term *Malthusian* was commonly used to denote a harsh and unfeeling view of human life. Nor was it difficult, for those who were offended at the conclusions gathered, to show that the premisses were overstated. It does not follow that all marriages are fertile; on the contrary, it is notorious, as is learnt from the records preserved of particular families, that many are not prolific; and if families are by any circumstances so separated as to be precluded from additions external to them, it is found, that, however numerous they are at first, they rapidly die out. It is very doubtful whether, supposing a nation were kept free from foreign immigration, its numbers would notably increase, and it is probable that the ordinary conditions and habits of modern civilisation are not by any means favourable to fecundity. It is alleged that the circumstances under which population increases most rapidly, at any rate where the births are in great excess, are those rather of hardship than of plenty; and this so remarkably, that Mr. Doubleday has made it the foundation of a theory of population, extravagant perhaps, but still plausible, in which the leading feature is that human beings are more fertile when, as in late marriages, they are least likely to be represented in their offspring, because they are near the time in which the reproductive functions cease; just as (to use Mr. Doubleday's language) a fruit-tree which is failing puts out its largest crop just before it ceases to bear any more. That marriages are more fertile when the parents are exceedingly poor and driven to great straits in order to procure subsistence, was seen by Adam Smith; that the danger, therefore, of excessive population lies in the pre-existent misery of parents, has been urged by many opponents of the doctrine of Malthus. Again, it may be doubted whether invention and adaptation in agricultural science may not invert the characteristic which Malthus thought he discovered in the rule of the production of food. It is probable that, since the time in which Malthus wrote, the rate of production has been doubled, and this at no greater charge for labour. It is certain that, in the developement of modern civilisation, in the abandonment of international jealousies, and in the slow but certain influence now exercised by the best interests of humanity against the selfish fears of administrations, the state of things in which any country makes itself voluntarily like a beleaguered city in its seclusion from the reciprocities of trade, is getting more and more remote. The value of the theory which Mr. Malthus announced lay, first, in its instant application to the social practice of his day, and in the truth which it contained; its error, a natural error, lay in the fact that at that time it could hardly be expected that a better and wiser course of international policy would lead men to understand that the interests of humanity were far more powerful than those of a miscalled patriotism.

The risks of over-population, to which Malthus called attention, are therefore, we believe, remote in the present time, partly because the area from which the supply of food can be procured is so extensive and so extensible, partly because the customary food of the people of England is found in the most costly kind of grain. That the condition of many who live by wages in this country, and especially in

agricultural districts, is one of great poverty, is doubtless true; but it must be remembered that this distress is being lightened by a real rise in wages; the average earnings, even of agricultural labourers, having considerably increased, and the power of purchase, owing to free trade in corn and the reduction of taxation, being far greater than twenty years ago. Nor can there be a doubt, that, if agricultural and other labourers would exercise the same prudence in postponing their marriage which is practised in every other condition of life, by abstaining from marriage till such time as they were possessed of some capital, and were, comparatively speaking, independent of the common casualties of their calling, their condition, even if they had subsequently as many children as now, would be infinitely bettered. As it is, they clog themselves in the very beginning of their industrial life, lose the power of moving from place to place, and with this inability abandon all hope and energy towards improving their prospects. In Cumberland and Westmoreland, the average rate of agricultural wages is 16*s.* a week, and the labourers will sooner emigrate than take less. That they may be able to do so in case the necessity arises, they take care to be possessed of some savings.

It does not follow, as some persons have rather hastily argued, that a slow increase or stationary position of the population in any one country is a sign of greater prudence on the part of its inhabitants. The people may be in such countries close upon the margin of subsistence. To discover whether this be the fact, we must take the ordinary earnings of the poorer classes, whether they be small proprietors or labourers for wages, and compare the amount with the price of the necessaries of life. Great stress has been laid, for instance, on the prudential habits of the French, and some among the Germans. But if it be found that the average means of subsistence possessed by these people is scanty, and much below that, for instance, of the English labourer, the condition of over-population is reached already. It must be observed, also, that where legislative arrangements prevent marriage, there is, in ordinary cases, sure to be a great increase of bastardy. In Munich, for instance, where regulations prohibiting marriage exist, and a system which has been incautiously praised is in full force, the illegitimate births are nearly as numerous as the legitimate, and the industrial energies of the community are of the lowest order. On the whole, we may conclude, that if the working classes in this country possessed a little more prudence in delaying marriage, they might secure to themselves a larger measure of independence, and ultimately a larger rate of wages, than they have ever yet experienced.

The subjoined table gives the population of the principal European communities, with that of the United States, and as far as possible the decennial percentage of increase:—

States	Date of Census	Population, 000 omitted	Area sq. miles	Population per sq. mile
Belgium	1856	4,530	11,313	401
Netherlands	1861	3,373	10,905	309
Great Britain and Ireland	1861	29,071	119,924	242
Italy	1864	21,777	98,784	221
German States	1861	18,071	95,347	189
France	1861	37,382	211,852	176
Switzerland	1860	2,534	15,233	157
Prussia	1861	18,497	107,300	156
Austria	1857	35,019	236,311	148
Denmark	1860	1,600	14,493	110
Portugal	1858	3,585	36,510	98
Spain	1857	16,302	182,758	90
Turkey in Europe	estimate	15,500	203,628	76
Greece	1861	1,329	19,340	68
Russia in Europe	1858	65,845	2,043,399	32
Sweden and Norway	1861	5,351	291,903	18

Density of Population on the Globe.

	Population, 000 omitted	Area, 000 omitted	Population, sq. mile
Europe	280,000	3,701	75
Asia	780,500	17,805	44
Africa	80,000	11,475	7
America	79,000	15,840	5
Australasia	1,500	2,582	1

Populin. A crystallisable substance separated from the bark of the poplar-tree, *Populus tremula.*

Porcate (Lat. porca, *a ridge*). In Entomology, when a surface has several parallel elevated longitudinal ridges.

Porcelain. [POTTERY.]

Porcelain Clay. [KAOLIN.]

Porcelain Spar. A silicate of alumina, lime and soda, with chloride of potassium; found at Obernzell in Bavaria.

Porcellanite or **Porcelain Jasper.** Clay altered by heat, so as frequently to resemble jasper.

Porch (Fr. porche). A small building erected to shelter the entrance of a church, or other edifice. Porches had frequently a chamber over them, used as a chapel or a muniment room.

Porcupine (Ital. porcospinoso). The name of a genus of Rodents (*Hystrix*) distinguished by the developement of free and voluntarily movable spines amongst the hair. They are found throughout Southern Europe, and allied generic forms exist in North America. [HYSTRICIDÆ.]

Porcupine Wood. The hard outer portion of the trunk of *Cocos nucifera.*

Pores (Gr. πόροι). In Astronomy. [SUN.]

PORES. In Natural Philosophy, the small interstices between the particles or molecules of matter which compose bodies. There are many considerations which prove that all bodies, even the densest, are composed of molecules, not in absolute contact, but separated from each other by intervals, which, though so small as to be inappreciable to the senses, have nevertheless a magnitude con-

siderable in respect of the molecules themselves; and it has been inferred that gold has more pores than solid parts; whence any substance of the specific gravity of water must have many times more pores than solid parts.

Porifera (Lat. porus, *a pore*, and fero, *I carry*). A name invented and applied by Mr. Hogg to a group of Polypes, including the genera *Cellepora*, *Millepora*, and *Tubulipora*: also used by Dr. Grant to designate the class of organised beings including the marine and freshwater sponges.

Porism (Gr. πόρισμα, from πορίζω, *I supply*). In Geometry, this word is defined by Prof. Playfair to be 'a proposition affirming the possibility of finding such conditions as will render a certain problem indeterminate, or capable of innumerable solutions.'

The following may serve as an example of a porism:—

A triangle being given in position, a point in it may be found such that any straight line whatever being drawn through that point, the perpendiculars drawn to this straight line from the two angles of the triangle which are on one side of it, will be together equal to the perpendicular drawn to the same line from the angle on the other side of it.

According to Pappus, the porisms constituted one of the eight subjects which formed the ancient geometrical analysis. Euclid composed a treatise on porisms in three books, of which no trace now remains, except some obscure hints preserved in the mathematical collections of Pappus. From the manner in which the porisms are mentioned by Pappus, it is evident that the ancients set a high value on this class of propositions; but the description which he has given of them is so vague, that geometers were long unable to divine his meaning, or to discover the peculiar circumstances in respect of which a porism differs from an ordinary problem. The subject, indeed, baffled the ingenuity of the most eminent mathematicians, until it was taken up by Dr. Simson, of Glasgow, who at length succeeded in restoring a great number of Euclid's porisms, together with their analysis. The propositions thus restored form a part of his posthumous works, published in 1776, at the expense of Earl Stanhope. It still remained, however, to enquire into the probable origin of the porisms, or the steps by which the ancient geometers had been led to their discovery; and also to point out the relations in which they stand to other classes of geometrical truths. This was accomplished by the late Professor Playfair, in an admirable paper 'On the Origin and Investigation of Porisms,' published in vol. iii. of the *Transactions of the Royal Society of Edinburgh*, and afterwards in the third volume of his collected works, Edin. 1822.

The most recent and perhaps the most valuable work on the subject is by M. Chasles, and is entitled, *Les trois Livres de Porismes d'Euclide rétablis pour la première fois, d'après la Notice et les Lemmes de Pappus et conformément au sentiment de R. Simson sur la forme des Énoncés de ces Propositions*, Paris 1860.

Porosity. A property of matter, in consequence of which its molecules are not in absolute contact, but separated by intervals or *pores*. The quantity of matter in a body is inversely as its porosity; whence the ratio of the porosity of one body to another may be determined from their weight. [Pores.]

Porphyry (Gr. πορφύρα, *purple*). A term in common use among geologists, to signify any rock in which crystals are embedded in an earthy or compact base. Thus granite in which crystals of felspar and mica are embedded in crystalline quartz, but not with crystals of quartz, is a porphyritic rock, and a mass of felspar with crystals of quartz and mica would be spoken of under the same general term. It will be evident, therefore, that the term is extremely *inclusive*, perhaps too much so to admit of a good definition. Many of the varieties of porphyry are named from their base, as greenstone porphyry, hornstone porphyry, &c.

The original meaning of porphyry is connected with the colour (red) which characterised the syenites of Egypt; but the use of the term is now altogether technical, and quite independent of colour.

The ordinary kinds of porphyry used in the arts are grey, red, and purple, the latter including a great variety of tints. They are not worked on a large scale, except in Russia and Scandinavia, where the raw material is obtained from large boulders lying on the surface of the ground.

The difficulties involved in the manipulation render the work of cutting and polishing so costly, that the objects manufactured are rather imperial presents than objects of commerce.

It has been supposed that in former times there were greater facilities for working porphyry than now exist, but this is not probable. Like all stones, the material was no doubt much softer when recently taken from the quarry than when obtained from boulders exposed for centuries to the air; but it was chiefly the small value of labour, and the indifference to the time needed for the work, that enabled the ancient Egyptians to cut and polish the magnificent vases and columns so common in the museums throughout Europe.

Porpita (Gr. πόρπη, *a buckle*). The name of a genus of sea-nettles (*Acalephæ*), characterised by an internal circular flattened disc of a calcareous and horny texture.

Porpoise (Fr. porc-poisson). [Phocæna.]

Porrect (Lat. porrectus, part. of porrigo, *I extend*). In Zoology, when a part extends forth horizontally, as if to meet something.

Porrigo (Lat. *scurf*). The ringworm, or scald-head.

Port. The canals or orifices provided for the passage of fluids in machinery are called *ports*; thus *steam-ports, water-ports, gas-ports*, are commonly mentioned.

The Latin words porta and portus, the former meaning *a gate*, the latter *a haven*, are probably akin to the Greek πύλη, περάω, and the English *ford*. [FRITH.]

PORT. [HARBOUR.]

PORT. The opening or embrasure in the ship's side for a gun. The ports of the lower deck are defended, when at sea, by strong covers hanging from hinges; the ropes by which these are held up or open are called *port lanyards*, and consist of a pendant passing through a leaded hole in the side with a tackle.

PORT. In Navigation, the modern term for *larboard*.

Port Royalists. The name popularly given to the members of the celebrated convent of the Port Royal des Champs. It was founded about 1204 by Matthieu de Marli, on the eve of his departure for the Holy Land; and it gradually acquired such importance as to secure for it a prominent place in the history of Europe. For the details of its varied fortunes, and the religious controversies which it carried on in the seventeenth century, the period of its greatest importance, we refer the reader to the learned work of Reuchlin (*Geschichte von Port Royal*), and to Sainte-Beuve's *Histoire du Port Royal*. It was abolished by Louis XIV. as a nest of Jansenists and heretics. Among the distinguished names connected with the Port Royal are those of Lancelot, Pascal, Arnauld, Nicole de Sacy, and Tillemont. The school books which were published for the use of that institution were translated into all the languages of Europe, and maintained their reputation long after its abolition; and though they are now fallen into disuse, the following deserve especial mention: 1. *Nouvelle Méthode pour apprendre la Langue Latine*; 2. *Nouvelle Méthode pour apprendre la Langue Grecque*; 3. *Grammaire Générale, &c.*

Port-fire. In Artillery, the *common port-fire* consists of a paper case about sixteen inches long, driven with a composition which burns at the rate of rather more than one inch a minute.

The *slow port-fire* consists merely of paper impregnated with saltpetre, and rolled into a solid cylinder about sixteen inches long, which will burn from two to three hours.

Portal (Lat. porta, *a gate*). In Anatomy, this term is applied to a system of veins that ramify like arteries, and send the blood from trunks to branches in the substance of the liver. The portal system is derived in mammals from the veins of the abdominal organs of digestion, which form a common trunk, called *vena portæ*. This subordinate kind of circulation in the liver is called the *portal circulation*, and the blood it transmits is called the *portal blood*. The blood of the portal veins differs from other venous blood in being of less specific gravity, darker, and incapable of being rendered bright by the contact of salt or oxygen; in containing only about half the ordinary quantity of fibrin, and in containing less albumen, but more red globules, and nearly twice the usual amount of fatty matter.

PORTAL. In Architecture, the lesser of two gates, when they are of two dimensions, at the entrance to a building.

Portcullis (Fr. portecoulisse). In Fortification, a sliding frame of wood or iron, shaped like a harrow, and formerly hung over the gateway of a fortified place, to be let down in a vertical groove, if the outer gate should be forced.

Porte, The Sublime. The official title of the government of the Ottoman Empire: said to be derived from a gate of the palace at Broussa, the original metropolis of that empire, called Bâb Humayoon, *the sublime gate*.

Porter (originally called *porter's beer*). A liquor brewed from malt, part of which has been more highly dried than that which is used for ale. It is hopped in the same way as ale; and its deep colour is finally given to it by roasted or parched malt. Porter was first brewed in 1722. The malt liquor previously drunk consisted of three kinds—ale, beer, and *two-penny*; and a mixture of either of these kinds was a favourite beverage under the name of *half-and-half*; or a mixture was drunk called *three threads*, consisting of equal portions of each of the above kinds of liquor, for a draught of which the publican had to go to three different casks. About 1722, Harwood, a London brewer, commenced brewing a malt liquor, which was intended to unite the flavours of ale and beer, or ale, beer, and *twopenny*; and having succeeded, he called his liquor *entire*, or *entire butt*; a name intended to intimate that it was drawn from one cask or butt only. A mixture of ale or porter, drawn from different casks, is very commonly drunk in London at the present time. Harwood's liquor obtained the name of porter from its consumption by porters and labourers. From 1722 to 1761, the retail price of porter was 3*d*. per pot, when it was raised to 3½*d*., at which it continued till 1799; it has never been higher than 6*d*., nor during the present century lower than at the present time, when the price is 4*d*. Since the abolition of the beer duties in 1830, the price has been 33*s*. per barrel. [TAXATION.]

Portico (Lat. porticus). In Architecture, a place for walking in under shelter, occasionally raised after the manner of a gallery with arches. Sometimes the portico is vaulted, sometimes it is covered with a flat ceiling. The most usually recognised application of the word is to the projection supported by columns placed before a building, and in this case it may be tetrastyle, hexastyle, octostyle, decastyle, and so forth, according to the number of its columns.

Portion (Lat. portio). In Anatomy, a term applied to two branches of the seventh pair of nerves; the *portio dura*, or hard portion, and the *portio mollis*, or soft portion: the former is the facial nerve, the latter the auditory or acoustic nerve.

Portion, Disposable (Fr. quotité disponible). In French Law, that portion of his property which a person may leave by will to

whom he pleases: amounting to a fourth where the testator has three or more children; a third, where he has two; half, where he has one child, or no child, but relatives capable of succession on the side both of father and mother; three-fourths, where he has relatives only in one ascending line.

Portite. A silicate of alumina, magnesia, and lime, found in the gabbro rosso of Tuscany, and named after M. Porte.

Portland Powder. A medicine consisting of equal parts of the roots of *Aristolochia rotunda* and *Gentiana lutea*.

Portland Stone. An important building material obtained from the upper part of the oolitic series of rocks, and chiefly quarried in the island of Portland. It is perhaps the best building stone in England when well selected, but it is heavy and dear, and there are very bad portions that must be carefully avoided. The best bed is near the top, and is from three to eight feet thick. Other inferior but still excellent beds are much worked. St. Paul's Cathedral and Greenwich Hospital are both excellent specimens of Portland that has resisted the attacks of time and weather in a London atmosphere.

Portland Vase. A celebrated cinerary urn or vase, long in the possession of the noble family of the Barberini at Rome (whence it was called the Barberini vase). From the Barberini it passed into the possession of the Portland family, who deposited it in 1810 in the British Museum. This beautiful specimen of ancient art was found in the tomb of the emperor Alexander Severus and his mother Mammæa. It is described by Montfaucon (*Antiq. Expliqué*, tom. v.), who was evidently mistaken in representing it as formed of a precious stone. The substance is said to be of glass, or composition; it is of a deep blue or violet colour, and the figures in the scene depicted on it are white. The subjects are mythological, but have been very imperfectly explained. (See two memoirs upon it, by Dr. King and W. Marsh, in the 8th volume of the *Archæologia*, and one by Dr. Darwin in the Notes to his *Botanic Garden*.) The late Mr. Wedgwood made a mould of this vase, and took from it a number of casts wrought with the greatest skill, and perfectly resembling the original.

Portrait (Fr.). In Painting, strictly the picture of any object taken from nature, or generally the representation of an individual, or, more strictly speaking, of the human face, painted from real life. Portraits are of full-length, half-length, kit-cat size, and three-quarters, &c.; and are executed in oil or water colours, in crayons and in miniature. Whole lengths and half-lengths vary in size; the kit-cat, so called from the size chosen by the old club of that name, from Christopher Cat, the master of the house in which the club was held, was a yard in height, by three-quarters of a yard in width.

Portraits are almost coeval with the earliest efforts in painting; they were not uncommon among the Egyptians. The Greeks exhibited iconic figures of their generals, in their public buildings, shortly after the Persian war, the Romans painted their portraits upon their shields, and these were sometimes dedicated in the public temples after the death of the owners. They also placed portraits of writers in the public libraries, over the cases containing their works; and the upper classes preserved wax portraits of their ancestors, which were carried in the funeral procession, when any distinguished member of the family died. These were the *imagines majorum*, the possession of which constituted a proof of nobility, as none but those families who had borne some curule magistracy had the privilege of having their portraits [Jus]; families boasted of their smoky images, *fumosæ imagines*, to show the antiquity of their houses.

Among great portrait painters are most conspicuous, Apelles, John van Eyck, Leonardo da Vinci, Raphael, Titian, Tintoretto, Moroni, Sebastian del Piombo, Jacopo da Pontormo, Bronzino, Velazquez, Holbein, Rubens, Vandyck, Rembrandt, Reynolds, Gainsborough, &c. (Wornum, *Epochs of Painting, &c.* 1864.)

Portreeve or **Port Greve** (A.-Sax. gerefa). The principal magistrate in Anglo-Saxon ports and maritime towns. According to Camden, this was the ancient title of the officer who was afterwards called mayor of London.

Portulacaceæ (Portulaca, one of the genera). A small order of hypogynous Exogens of the Silenal alliance, known by their consymmetrical flowers, their amphitropal ovules, and alternate leaves without stipules. The typical genus is *Portulaca*, one species of which, *P. oleracea*, under the name of Purslane, was formerly cultivated as a potherb.

Poseidon. In Greek Mythology, a son of Kronos and god of the sea, standing to Nereus in a relation corresponding to that of Phœbus to Helios. [Zeus.]

Posidonia Schist. A somewhat important bituminous shale belonging to the lias, and very extensively distributed over Europe. The *Posidonia* is a flat bivalve shell. It appears often in incredible abundance, almost composing a mass of black shale, but mixed up with so large a quantity of carbon in the form of bitumen, that it is valuable for distilling. There are now several establishments in Germany where the Posidonia schist of the lias is worked for distillation.

Position (Lat. positio, from pono, *I place*). A rule in Arithmetic, called also the rule of supposition, or *rule of false*. It consists in assuming a number, and performing upon it the operation described in the question, and then comparing the result with that given in the question, in order to discover the error of the assumption. Writers on arithmetic divide the rule into two parts, *single position* and *double position*; the former comprehending those questions in which the results are proportional to the suppositions, and where, consequently, only one assumption is required;

the latter those in which the results are not proportional to the suppositions, and where two suppositions are necessary in order to deduce the true answer. To simple position belong such questions as the following: What number is that from which, if a third and a fourth of itself be subtracted, the remainder is 60? Double position comprehends questions of this sort: What number is that which, being multiplied by 6, the product increased by 18, and the sum divided by 9, the quotient shall be 20? It will be observed that both these questions are immediately solved by a simple algebraic equation. Position is also called the *rule of trial and error*, and is sometimes employed with good effect in approximating to the roots of numerical equations.

Position. In Painting, the placing of the model in the manner best calculated for the end in view by the artist.

Position, Angle of. In Astronomy, the angle made by one or more components of a double or multiple star with the primary, referred to the direction of the diurnal motion. It may also indicate the direction of a comet's tail, &c.

Positive Electricity. [Electricity.]

Positive Quantity. In Algebra, this term denotes an affirmative or additive quantity, which character is indicated by the sign +, called, in consequence, the *positive sign*. The term is used in contradistinction to *negative*; negative quantities being such as are subtractive, and marked by the sign —, which is called the *negative sign*. [Sign.]

Positivism. This word is commonly used to designate the system of philosophy maintained by M. Comte, who is vaguely supposed to have originated a method unknown to philosophers before his time. Like most popular notions, this is a mistake. M. Comte certainly strove to systematise the whole field of knowledge; but the ground on which he raised his gigantic fabric is that on which all philosophers who have really promoted the advance of science, have commonly worked. His fundamental doctrine, in his *Cours de Philosophie Positive*, is that we have no knowledge of anything but phenomena, and that our knowledge of phenomena is relative, not absolute, i. e. that we know not the essence or the real mode of production of any fact, but only its relations to other facts in the way of succession and similitude. This doctrine is practically that of Galileo, Bacon, and Descartes; and to this conclusion, that the only knowledge accessible to us is that of the successions and sequences of phenomena, we owe the whole progress of science during the last four centuries. But the distinguishing characteristic of M. Comte's philosophy was the hypothesis that all human conceptions pass through three stages, the theological, the metaphysical, and the positive. The nomenclature is his own, and although it is open to many objections, his conceptions cannot be adequately unfolded except in his own terminology. The theological stage of thought he again subdivided into Fetichism, Polytheism, and Monotheism, 'the successive transitions being prepared, and indeed caused by, the gradual uprising of the two rival modes of thought, the metaphysical and the positive, and in their turn preparing the way for the ascendency of these; first and temporarily of the metaphysical, and lastly of the positive.'

This doctrine, which takes no account of anything but an ascertained order of phenomena, is not unfrequently charged with atheism. M. Comte apparently rejected the idea of the dependence of nature on an Intelligent Will; but the adoption of his principle of experience, which is the principle of Bacon and of Newton, by no means necessarily involves his conclusion. The positive theory merely throws back the question of an Intelligent Will, instituting the cosmos, to the origin of all things. 'The laws of nature cannot account for their own origin. The positive philosopher is free to form his opinion on the subject, according to the weight he attaches to the analogies which are called marks of design, and to the general traditions of the human race.' It is compatible with M. Comte's system to believe 'that the universe was created, and even that it is continuously governed by an intelligence, provided we admit that the intelligent Governor adheres to fixed laws, which are only modified or counteracted by other laws of the same dispensation, and are never either capriciously or providentially departed from. Whoever regards all events as parts of a constant order, each one being the invariable consequent of some antecedent condition or combination of conditions, accepts fully the positive mode of thought, whether he acknowledge or not a universal antecedent on which the whole system of nature was originally consequent, or whether that universal antecedent is conceived as an intelligence or not.'

M. Comte has been also charged with repudiating metaphysics; but it is a mistake to suppose that he interdicted himself 'from analysing or criticising any of the abstract conceptions of the mind,' although with all his strength he opposed the ideas which regard mental abstractions as real entities. His crusade against these realistic theories, which the Baconian philosophy professes utterly to eschew, led him into an elaborate and masterly survey of the developement of human thought and knowledge, the result of which showed that fetichism preceded polytheism, and that the exhaustion of the latter prepared the minds of all genuine thinkers for the reception of a monotheism such as that of Christianity, 'which has persisted to the present time in giving partial satisfaction to the mental dispositions that lead to polytheism by admitting into its theology the thoroughly polytheistic conception of a devil.' This tendency to monotheism was the result of a practical feeling of the invariability of natural laws; but for many centuries the monotheistic creed so introduced

was belief in a God 'flexible by entreaty, incessantly ordering the affairs of mankind by direct volitions, and continually reversing the course of nature by miraculous interpositions.' Here, again, according to M. Comte, the influences which led to the decay of polytheism had a further field for action. The increased assurance of a natural order gradually excluded the idea of such interferences; and the metaphysical stage, which followed this exclusion, has given way or is yielding to the positive mode of regarding all phenomena in the one aspect of sequence or succession.

On these principles M. Comte undertook the Herculean task of arranging all sciences according to the degree of the complexity of their phenomena, so that each science shall depend on the truths of all those which precede it with the addition of peculiar truths of its own. But for further details of his plan and of the method in which he carried it out, and for a more complete examination of his philosophy in its earlier and later aspects, we must refer the reader to the elaborate articles in which Mr. J. S. Mill has analysed the merits and defects of M. Comte as a philosopher and a sociologist. (*Westminster Review*, April and July, 1865; these articles have since been republished.) On a subject so vast, and so encumbered with controversy, we have confined ourselves to giving, as nearly as possible, in Mr. Mill's words, a brief account of his primary doctrines, which may serve to give a true, although necessarily inadequate, idea of his system. We refer the reader also to an article entitled 'Comte and Positivism,' in *Macmillan's Magazine*, March 1866), in which Dr. Whewell maintains that the history of every science would reveal to us how baseless is the notion that there is a good positive stage of science which succeeds a bad metaphysical stage.

Posology (Gr. πόσος, *how much*; and λόγος, *description*). In Medicine, that which relates to the doses or quantities in which medicines should be administered.

Posse Comitatus (Lat. cum potestate comitatus). In Law, the power of the county, which the sheriff is empowered to raise in case of riot, possession kept on forcible entry, rescue, or other force made in opposition to the king's writ or execution of justice. It is said to include all knights and other men, above the age of fifteen, able to travel within the county. Justices of the peace may also raise the posse in order to remove a force in making entry into or detaining lands.

Post (Lat. positus, part. of pono, *I place*). In Public Economy, a messenger, courier, or conveyance travelling at stated periods, and generally with more than ordinary speed, to convey letters or other despatches, whether of government or individuals. [POST OFFICE.]

Post Mortem (Lat. *after death*). In Anatomy, the technical phrase signifying the inspection and examination of the dead body in order to determine the cause of death: it is also applied to the appearances presented, and more especially to some phenomena which are constantly noticed shortly after death. Thus, the muscles retain their property of contracting under the influence of stimuli applied to them, or to their nerves, for some time after death; and when they have lost this irritability, they spontaneously pass into a state of contraction, producing a general stiffening of the body, which is called *post-mortem rigidity*, or *rigor mortis*.

Post Obit (Lat. post obitum, *after death*). A bond given for the purpose of securing a sum of money on the death of some specified individual.

Post Office. A place for the reception and distribution of the letters and despatches that are to be or that have been carried by the post; where the duties on them are paid, and where the various departments connected with the business of the post are conducted or superintended.

The conveyance of letters by post is one of the few industrial undertakings which are certainly better managed by government than they could be by individuals. It is indispensable to the satisfactory working of the post office that it should be conducted with the greatest regularity and precision; and that all the departments should be made subservient to each other, and conducted on the same plan. It is plain that such results could not be obtained in any extensive country otherwise than by the agency of government; and the interference of the latter is also required to make arrangements for the safe and speedy conveyance of letters to, from, and through foreign countries.

The organisation of the post office supplies one of the most striking examples of the advantages resulting from the division and combinations of employment. 'Nearly the same exertions that are necessary to send a single letter from Falmouth to New York will suffice to send 50,000. If every man were to effect the transmission of his own correspondence, the whole life of an eminent merchant might be passed in travelling, without his being able to deliver all the letters which the post office forwards for him in a single evening. The labour of a few individuals, devoted exclusively to the forwarding of letters, produces results which all the exertions of all the inhabitants of Europe could not effect, each person acting independently.' (Senior *On Political Economy*.)

Posts appear to have been established for the first time in modern Europe in 1479, by Louis XI. of France. They were originally intended to serve merely for the conveyance of public despatches, and of persons travelling by authority of government. Subsequently, however, private individuals were allowed to avail themselves of this institution for forwarding letters and despatches; and governments, by imposing higher duties or rates of postage on the letters and parcels conveyed by post than are sufficient to defray the expense of the establishment, have rendered it productive of a

considerable revenue. Nor, while the rates of postage are confined within reasonable limits, and do not materially affect the facility of correspondence, is there, perhaps, a less objectionable tax.

The post office was not established in England till the seventeenth century. Postmasters, indeed, existed in more ancient times; but their business was confined to the furnishing of post horses to persons who were desirous of travelling expeditiously, and to the despatching of extraordinary packets upon special occasions. In 1635, Charles I. erected a letter office for England and Scotland; but this extended only to a few of the principal roads; the times of carriage were uncertain; and the postmasters on each road were required to furnish horses for the conveyance of the letters at the rate of 2½*d.* a mile. This establishment did not succeed; and, at the breaking out of the civil war, great difficulty was experienced in the forwarding of letters. At length a post office, or establishment for the weekly conveyance of letters to all parts of the kingdom, was instituted in 1649, by Mr. Edward Prideaux, attorney-general for the Commonwealth; the immediate consequence of which was a saving to the public of 7,000*l.* a year on account of postmasters. In 1657, the post office was established nearly on its present footing, and the rates of postage that were then fixed were continued till the reign of Queen Anne. (Black. *Com.* by Stephens, vol. ii. pp. 576–8.)

From the establishment of the post office by Cromwell, down to 1784, mails were conveyed either on horseback, or in carts made for the purpose; and instead of being the most expeditious and safest conveyance, the post had become, at the latter period, one of the slowest and most easily robbed of any in the country. In 1784, it was usual for the diligences between London and Bath to accomplish the journey in *seventeen* hours, while the post took *forty* hours; and on other roads the comparative rate of travelling of the post and stage coaches was in about the same proportion. The natural consequence of such a difference in point of despatch was, that a very great number of letters were sent by other conveyances than the mail: the law to the contrary being easily defeated, by giving them the form of small parcels.

Under these circumstances, it occurred to Mr. John Palmer, of Bath, comptroller-general of the post office, that a very great improvement might be made in the conveyance of letters, in respect of economy, as well as of speed and safety, by contracting with the proprietors of stage coaches for the carriage of the mail; the latter being bound to perform the journey in a specified time, and to take a guard with the mail for its protection. Mr. Palmer's plan encountered much opposition, but was at length carried into effect with the most advantageous results. The use of mail-coaches speedily extended to most parts of the empire; and, while letters and parcels were conveyed in less than half the time that had been required under the old system, the coaches by which they were conveyed afforded, by their regularity and speed, a most desirable mode of conveyance for travellers. Mr. Palmer was the author of several other improvements in the economy of the post office; nor is there any individual to whom the department owes more. (Macpherson's *Annals of Com.* anno 1784.)

Within the last few years, however, the construction of railways between most of the great towns of the empire has gone far to supersede the use of mail coaches on the principal lines of road, and has added prodigiously to the facilities of correspondence and travelling. The journey from London to Liverpool, which had been accomplished by the mail in about twenty or twenty-two hours, is now accomplished, by railway, in nine or ten hours; and on other roads in the same proportion. The great expense of the post office consists, in fact, not so much in the conveyance of letters from place to place, as in their previous collection and their distribution after they have been conveyed to their destination. This necessitates the establishment of a vast number of subordinate offices in the remoter parts of the kingdom, many of which do not defray their expenses. Much of this expense, however, has been obviated of late years by economy in the means of collection, especially by the establishment of pillar letter boxes in substitution for offices in town and village shops.

Up to 1839, the rates of postage levied on the carriage of letters were exceedingly high, amounting, it is said, to a fraction above 7*d.* on each letter. The post office was treated practically as a tax on private correspondence, for the monopoly of the post was cautiously guarded by penal clauses inflicting heavy fines on any person who made use of any method of transmitting letters besides that provided by government. These penal clauses were probably inoperative, or, if they had any operation, must have affected only the inexperienced and unwary. It is certain that, notwithstanding the great growth of foreign and home trade, the revenue of the post office remained almost stationary for twenty years; in other words, its provisions were evaded. Under such circumstances some remedial measure became absolutely necessary. This was discovered, or at least elaborated, by the secretary of the post office, Sir Rowland Hill, and the scheme suggested by him was, in its leading features at least, carried out by the government.

The fundamental principle of the new Post Office Act, was that the rate paid should be uniform, on the ground that the charge levied was not for carriage, this being in so light a matter as a letter unimportant, but for collection and distribution. The rate at which the service should be appraised was not, it appears, so essential a consideration; though it was felt that, on the whole, government, acting in the carriage of letters as a trader, should not seek to obtain an exorbitant rate of profit

for the service rendered. However, after a short period, during which the maximum rate was 4*d*., the uniform sum of 1*d*. was imposed, and the weight suffered to pass at this rate was fixed at half an ounce. Another feature in the new postal system was that of enforcing the prepayment of letters by levying a fine of one hundred per cent. as the postage on unpaid letters. The advantage of this regulation is obvious: it saves the labour of collection and distribution to a great extent. An attempt, indeed, was made to insist still more urgently on the necessity of prepayment, by issuing a regulation to the effect that unstamped letters would not be forwarded. We are not informed as to the amount of loss consequent upon the collection of double rates for unpaid letters; but when the above-mentioned regulation was issued, the opposition to it, due, as far as it can be interpreted, to selfish and sentimental motives, was so strong that the rule was withdrawn. Previous also to the new Post Office Act, members of parliament had the privilege of sending free a certain number of letters daily. The privilege was abused, no doubt. It was abolished by the Act, and no letters are sent free except petitions intended to be presented to the houses of parliament, and bearing evidence of their nature. Even the public offices, though they send official letters which are unstamped, and practically unpaid, are debited with the postage, the aggregate amount due from each office forming part of its annual expenses.

Many persons objected strongly, at the time of passing the new Act, to the rate at which the postage would be levied for the future. The most powerful argument brought forward by the objectors, was that of the loss likely to accrue to the revenue; and it cannot be denied that the prediction was verified, the office having only lately returned annual profits equal to those obtained before the alteration was made. But the moral advantages of a cheap postal system are far more important than the mere question of the revenue derived from the post office; and beyond question the commercial benefits which have ensued from providing the means of cheap and ready communications have helped the revenue indirectly by returns infinitely in excess of that which could have been obtained under the old system. Any tax on correspondence is a great bar to exchange, a serious hindrance to trade, and therefore a damage to the gross revenue derivable, as all revenue must be, from the profits of production and commerce. It is true that as long as the profit is in excess of the charge at which letters are collected and delivered, the rate is of the nature of a tax; but as long, on the other hand, as the government system provides means of communication at a rate lower than that at which joint-stock enterprise could do the same service, it is a gain to the public, and in so far as it represents a profit upon the capital employed in the labour, it is an advantageous method by which a nation trades on its own account. Nor is it to the purpose to compare the taxation of the old system, with a tax upon any convenience of life, as sugar or tea. Once paid, the taxes levied on such commodities as these have ceased to have any effect. But a heavy tax levied upon an act necessary for the purposes of trade produces far more loss than its first and immediate incidence. It hampers and hinders other operations, and in effect does what the worst tax does—costs a community far more than it gets for the revenue.

The post office has extended its operations in certain directions unknown and indeed impossible under the old régime, but now of great advantage to the nation, and in some cases of great profit to the government. First, it acts as a common carrier in the transmission of books and papers at low rates. The system of taxing newspapers was to some extent compensated by their exemption from the old postage rates. This, which was originally a mere act of reciprocity, has been since the reduction and ultimately the abolition of the stamp duty, continued on payment of the lowest stamp rate, or, supposing the newspaper to be below a certain weight, on a prepayment by a penny stamp. The advantage accorded to newspapers has since been on reasonable grounds extended to all printed matter and such writing as is not of the nature of a letter. Next, it has afforded a means by which additional security is afforded to letters of value. The post office has never been liable to the law of bailment, i.e. to the conditions attached to the function of a common carrier of compensating the owner of property intrusted to such a person for loss, damage, or delay. There are, indeed, obvious reasons why a government office should be exempted from such a general liability. By means of registration, however, a security is afforded to valuable letters and enclosures which is practically equal to the provisions of the law of bailments in the case of a common carrier. Thirdly, by means of post office orders the government has taken upon itself some of the functions of a bank. The rates at which this service is rendered are still probably too high, and amount in the transmission of small sums to a very heavy percentage, falling with undue weight on such of the poorer classes as are likely to transmit these small amounts. But, on the whole, the adoption of the government orders is of great public utility. And, lastly, it has been made the channel by which government has given the advantages of savings-banks at a moderate rate of interest, and with absolute security, to the public. This last scheme is only in its infancy; but it is very likely that hereafter it may be a very important means for dealing with a considerable portion of the public debt.

The postal system in this country has been, to a small extent, imitated by foreign governments. They have, for instance, all adopted stamps, and this even in the most remote regions. But very few of these communities have

adopted a rational postal system, or taken anything more than the superficial features of the English method. The arrangements, too, for the simplification and economy of international posts, are far from complete; and the difficulties put in the way of such arrangements as would facilitate communications between the inhabitants of various countries, are part of the barbarism which still attaches to modern administrations. Some progress, however, has been made, and more no doubt will be made, as communities learn to apprehend more clearly their real and abiding interests. In short, Sir Rowland Hill is one of the few fortunate persons who, having initiated a great reform, has not only lived to see it generally adopted, but has had the rarer satisfaction of seeing it generally approved by all enlightened and sensible persons.

Of late years a demand has been made for the reduction of postages between this country and others, especially between Great Britain to and from the colonies and the United States. Considering the importance of the trade between this country and those regions, and taking also into account that they are of the same origin with ourselves, and have very similar political, social, and even domestic interests, it seems to be a matter of the highest policy that communications between Great Britain and the Anglo-Saxon races should be facilitated to the greatest extent possible. We may repeat, that the gain and loss to the revenue in the establishment of ready means for commercial and social intercourse by no means represent the true gain accruing to the administration in the extension of trade, and to the communities themselves in the growth of mutual knowledge, intimacy, and kindly feeling.

Postage stamps perform, to a very large extent, the office of a minor form of paper currency in this country. They are not a legal tender: it may be doubted whether the transfer and sale of postage stamps, which is in effect the meaning of their use as currency, be not a violation of the stamp laws; but it is almost needless to observe, that public convenience is rarely hindered by such an innocent breach of fiscal regulations. In the United States, during the late civil war, postage stamps were made a legal tender for sums below a certain amount, and were, on the same principle and with similar limitations, receivable in payment of taxes. It is, perhaps, impossible at present to interpret the political and fiscal necessities which led to the Legal Tender Act of Congress; it is well known that a state paper currency has been a favourite expedient with the United States' government, and it is entirely premature to predict the period at which the resumption of cash payments will be made, and the injury inflicted on the recipients of fixed incomes by the Legal Tender Act redressed. It is quite clear, however, that the mischief of a forced paper is always proportioned in extent to the lowness of the denomination which is thus put into circulation.

Post Position. In Music, a retardation of the harmony, effected by placing discords upon the accented parts of a bar not prepared and resolved according to the rule for discords.

Posts. In Military operations in the field, *advanced posts* are placed at a distance from the main body. These for their own safety push forward *outposts*, which are supported by strong *pickets*. *Patrols* keep up the communication.

Post-abdomen. The name applied by Latreille to the five posterior segments of the abdomen of Hexapod insects; and to the tail of Crustaceans, which consists of homologous but more numerous segments.

Postage. The rate of charge levied on letters or other articles conveyed by post. [POST OFFICE.]

Postea (Lat.). In Law, the return of the judge before whom a cause is tried, after verdict, of what was done in the cause, which is endorsed on the back of the nisi prius record.

Postern (Fr. posterne, now written pôterne, Ital. postierla, Low Lat. posterula). In Architecture, a small door, or gate, at the back of a building.

POSTERN. In Fortification, a vaulted passage underneath a rampart, leading from the interior into the ditch, and closed by a gate.

Postill (said to be from Lat. post illa, *after them*). A title sometimes given in ecclesiastical language to a homily or sermon delivered *after* and upon a lesson or text taken from Scripture.

Postliminium or **Jus Postliminii** (Lat.). In National and Civil Law, the right by virtue of which persons taken in war return to their former state of freedom, with their former rights and property, on its termination; and property so taken reverts to its former owners.

In the middle ages the term also denoted the process by which a citizen, going to a foreign country, claimed for himself the rights of a subject and citizen of the land which he was leaving, so that on his return he was reinstated at once into his former condition.

Postscenium (Lat.). In Architecture, the back part of the theatre behind the scene, furnished with conveniences for robing the actors, and depositing the machinery.

Postulate (Lat. postulatus, part. of postulare, *to demand*). In Geometry and Logic, something to be assumed, or taken for granted. Euclid has constructed his *Elements* on the three following postulates: 1. That a straight line may be drawn from any one point to any other point. 2. That a terminated straight line may be produced to any length in a straight line. 3. That a circle may be described from any centre at any distance from that centre. (Playfair's *Euclid*.)

Pot Metal. An alloy of copper and lead. The term is also sometimes applied to glass as it comes from the glass-pots.

Potash. The saline matter obtained by lixiviating the ashes of wood. When purified by calcination it is termed *pearlash*, and is in that

state an impure *carbonate of potassa*. The production of potash is carried on upon a large scale in Russia and America; it can be thus obtained only in countries where there are vast natural forests, and where the value of timber is little more than that of the labour of felling it. [POTASSIUM.]

Potassa. [POTASSIUM.]

Potassium. This metal, represented by the symbol K, *kalium*, was discovered by Davy in the year 1807, and was one of the first fruits of his electro-chemical researches. Its properties were so remarkable, that it was for a time doubted whether it could with propriety be placed among the metals; but the progress of discovery removed all difficulty upon that point, by making us acquainted with other metallic substances with properties intermediate between those of potassium on the one hand, and the common metals on the other. The specific gravity of potassium is ·865 at the temperature of 60°; it is solid at the ordinary temperature of the atmosphere; at 80° it becomes soft, and at 150° is liquid; at 32° it is brittle, and has a crystalline texture. In colour and lustre it much resembles mercury. Its affinity for oxygen is such that it immediately loses its brilliancy on exposure to air; when heated in the air, it burns with a purple flame. The equivalent of potassium is 39, and that of *protoxide of potassium* is 47. When potassium is heated in oxygen it absorbs a larger quantity of that element and becomes a *peroxide*, which, however, is immediately converted into protoxide by the action of water. Protoxide of potassium exists in the state of *hydrate* in what is called *caustic potash*, which is a compound of ·47 potassa + 9 water. This substance fuses below a dull red heat; it is very soluble and deliquescent, and acts powerfully on almost all animal textures. It is the *lapis causticus* of old pharmacy. Dissolved in water, it forms *soap ley*, or the *liquor potassæ* of the *Pharmacopœia*. This solution is obtained by pouring water upon a mixture of equal parts of quicklime and carbonate of potassa; the lime abstracts carbonic acid from the carbonate, and becomes converted into an insoluble carbonate of lime, whilst the evolved potassa is taken up by the water. This solution is powerfully alkaline, and soon absorbs carbonic acid when exposed to air. Free potassa is recognised, when in solution, by its alkaline reaction upon test-paper, and it is distinguished from soda by adding to it excess of tartaric acid, when it yields a white granular precipitate of bitartrate of potassa. When potassa is in combination, as, for instance, when its salts are dissolved in water, they are detected, if the solution be not too dilute, by a strong solution of chloride of platinum, which causes a yellow precipitate of potassio-chloride of platinum.

When potassium and sulphur are heated together, they combine and form a sulphuret of potassium. With the acids potassa forms a variety of useful salts; such as nitre, or nitrate of potassa, with nitric acid; sulphate of potassa with the sulphuric acid; and carbonate of potassa with the carbonic acid. The latter is a very important salt; it forms the greater part of the residuum or ash of burnt wood, from which it is obtained by lixiviation. It is brought to this country from Russia and America, under the names of *pearlash* and *potash*, and consists of 47 potassa + 22 carbonic acid; it is deliquescent, and has an alkaline reaction. When carbonic acid is passed through a solution of this salt, it becomes converted into bicarbonate of potassa, composed of 47 potassa + 44 carbonic acid. Potassium burns with great splendour in chlorine, and forms chloride of potassium; it also combines with iodine, bromine, and fluorine, and with many of the metals.

Potato. The common name for the tubers of the *Solanum tuberosum*.

Potato Disease. This formidable malady, which first appeared in Great Britain in 1845, and is marked by the rapid putrescence of the leaves and haulm of the Potato plant, is now referred, and apparently with good reason, to the attack of a little fungus or mould called *Peronospora infestans*, which preys upon the tissues, spreading rapidly in every direction, so that the tubers become affected with brown spots both on their surface and within their tissue, and decay with greater or less rapidity. The mould would appear to be the primary cause; but as it attacks the tissues before it appears externally, it is almost impossible to apply a remedy. The two most important plans which have been adopted, though far from infallible, are the powdering of the sets with flowers of sulphur, and early planting The removal of the haulm as soon as the mould appears has also been found beneficial. The disease has been equally bad in the wettest and hottest seasons, and was in many districts as virulent in 1860 as on its first appearance, the worst year perhaps being 1846, when its sudden inroad produced a fearful famine in Ireland, which resulted in the death of thousands of the population, and led to the repeal of the corn laws.

German authors distinguish two forms, the wet and dry rot. It is, however, to be observed that these diseases, which are characterised not only by the peculiar condition of the tubers, but by the presence of *Fusisporium Solani tuberosi*, were prevalent in this country before 1845. The brown mottled appearance of the tubers, and the presence of *Peronospora* on the leaves and the exposed tissues, was previously unknown. (Berkeley, *Treasury of Botany*.)

Potency of a Point. The potency of a point, with respect to a circle, is the rectangle under the segments into which that point divides any chord of the circle which passes through it. The potency is clearly the square of half the shortest chord through the point, when the latter is within the circle, and the square on the tangent, when the point is without the circle. The term *potenz*, of which *potency* is Prof. Cayley's translation, was introduced by Steiner. (Crelle's *Journal*, vol. i.) The points of equal potency with respect to two circles lie in a right line, called by Steiner

the *line of equal potency*, by Magnus the *axis of collineation*, by Plücker the *chordale*, and by Gaultier the *radical axis*. The last name is the one now generally used. [RADICAL AXIS.]

Potential. In the Calculus of Attraction, the potential of a body, or system of bodies, relatively to a given point M, whose rectangular coordinates are x, y, z, is a certain function of these coordinates whose three first partial differential coefficients give, to a constant factor près, the three components of attraction or repulsion on a material particle placed at M. When the law of attraction is that of the inverse square of the distance, the potential may be defined as the sum of each mass-element of the attracting body divided by the distance of that element from the attracted point. It is expressed, therefore, by

$$V=\int\frac{dm}{r},$$

where the integration is to be extended to all the elements of the body. Calling R the resultant attraction on a material particle of the mass μ, situated at M (x, y, z), and X, Y, Z the components of attraction in the directions of the coordinate axes, we have

$$X=-\mu\frac{dV}{dx},\ Y=-\mu\frac{dV}{dy},\ Z=-\mu\frac{dV}{dz},$$

and hence

$$\frac{R}{\mu}=-\sqrt{\left(\frac{dV}{dx}\right)^2+\left(\frac{dV}{dy}\right)^2+\left(\frac{dV}{dz}\right)^2}.$$

An important property of the potential is expressed by the following differential equation:

$$\frac{d^2V}{dx^2}+\frac{d^2V}{dy^2}+\frac{d^2V}{dz^2}=-4\pi\rho,$$

where ρ represents the density of the attracting body *immediately around* the attracted point. When the latter is external to the attracting mass, therefore, the above sum vanishes, as was first shown by Laplace. In the above more general form the equation is due to Poisson.

The points relatively to which the potential has the same value, lie on the so-called *equipontial* or *equilibrium surface*, which is everywhere normal to the direction of the resultant, i.e. to the *lines of force*.

Legendre, Lagrange, Laplace, Poisson, and Gauss, were among the first to introduce the potential into mechanical investigations. The name, however, was originated by George Green, whose *Essay on the Application of the Mathematical Analysis to the Theories of Electricity and Magnetism*, Nottingham 1828 (reprinted in vols. xliv. and xlvii. of Crelle's *Journal*), together with Gauss' *Memoir on General Theorems relating to Attractive and Repulsive Forces varying inversely as the Square of the Distance* (*Result aus den Beob. des mag. Vereins*, Leipzig 1840, translated in Taylor's *Scientific Memoirs* 1842, and in Liouville's *Journal* 1842), are classic works on the subject. Chasles, too, has written several geometrical papers treating of the same matter; one of these will be found in the *Connaissance des Temps* for 1845. The works of Dirichlet, when collected, will probably contain the far-famed lectures on the calculus of attraction, delivered by him periodically at the university of Berlin, wherein the properties of the potential are fully developed.

Potential Energy. In Mechanics, a bent spring, a raised weight, or compressed air, &c. is said to possess *potential energy*, because it is in a condition to do work if allowed. Potential energy is measured by the work done in bringing the body to the condition in question. It is an important theorem in modern science that in a system of bodies, subjected solely to mutual actions, *the sum of potential and actual energy* (*vis viva*) *is always constant*. (Helmholtz *On the Conservation of Force*, Berlin 1847, and *Scientific Memoirs*, 1853; Rankine in *Phil. Mag.* 1853 and *Edin. Phil. Journ.* 1855; Tait and Steele's *Dynamics of a Particle*, &c.)

Potential Mood (Lat. potentia, *power*). In Grammar, that mood of the verb which expresses an action conceived as *possible*; denoted in English by the auxiliary verb *may* or *might*.

Potential Qualities. In Scholastic Philosophy, such qualities as are supposed to exist in a body *in potentia* only.

Potentilla (Lat. potens, *powerful*). A very showy genus of garden flowers, yielding numerous hardy herbaceous perennials of an ornamental character. It also contains several native species, mostly of a weedy aspect. The genus belongs to the *Rosaceæ*, and somewhat resembles the strawberry, to which it is allied.

Poterium (Lat.; Gr. ποτήριον, *a drinking cup*). A native English plant, the leaves of which resemble the fruit of the cucumber in flavour. It is, however, an agrarian weed, often troublesome in crops of saintfoin, and probably in such cases attributable to mixed or foul seed having been sown.

Potitii. Roman priests of Hercules, said to have been appointed by Evander. The myth of Hercules and Cacus furnishes the institutional legend. The two families of the Potitii and Pinarii performed the rites of Hercules about the ara maxima, the former being admitted to the feast while the latter were only allowed to minister at the sacrifice; or, according to another version, the Potitii were regaled on the entrails of the ox, the Pinarii being confined to the other parts of the animal. According to others, the word *potitii* had reference to the privilege of that family, the name *pinarii* being connected with the Greek πεινᾶν, *to hunger*, because they came too late for the banquet. Later legends said that Appius Claudius, when censor, induced the Potitii to transfer their functions to public slaves, whereupon the families of the gens Potitia died within the year, or, according to another account, within thirty days. (Sir G. C. Lewis, *Credibility of Early Roman History* i. 293.)

Potstone. A coarsely granular variety of Steatite or Soapstone, which on account of its tenacity, infusibility, and the ease with which it may be turned in the lathe, is frequently made into culinary vessels, especially in Italy, Corsica, Germany, France, and the island of Sark.

Pottery and Porcelain. The better kind of pottery, called in this country *Staffordshire ware*, is made of an artifical mixture of alumina and silica; the former obtained in the shape of a fine clay, chiefly from Devonshire and Dorsetshire; and the latter consisting of chert or flint, which is heated red-hot, quenched in water, and then reduced to powder. Each material, carefully powdered and sifted, is diffused through water, mixed by measure, and brought to a due consistency by evaporation: it is then highly plastic, and formed upon the potter's wheel and lathe into various circular vessels, or moulded into other forms, which, after having been dried in a warm room, are enclosed in baked clay cases resembling bandboxes, and called *seggars*; these are ranged in the kiln so as nearly to fill it, leaving only space enough for the fuel; here the ware is kept red-hot for a considerable time, and thus brought to the state of *biscuit*. This is afterwards glazed, which is done by dipping the biscuit-ware into a tub containing a mixture of about 60 parts of litharge, 10 of clay, and 20 of ground flint, diffused in water to a creamy consistence; and when taken out, enough adheres to the piece to give a uniform glazing when again heated. The pieces are then again packed up in the seggars, with small bits of pottery interposed between each, and fired in a kiln as before. The glazing mixture fuses at a comparatively moderate heat, and gives a uniform glossy coating, which finishes the process when it is intended for common white ware.

The patterns upon ordinary porcelain, which are chiefly in blue, from the facility of applying oxide of cobalt, are generally first printed off upon paper, which is attached to the plate or other article while in the state of biscuit; the colour adheres permanently to the surface when heat is properly applied: other mineral colours, such as the oxides of chromium and manganese, are also occasionally employed in the same way.

The manufacture of PORCELAIN is a more refined branch of art; the materials are selected with the greatest caution, it being necessary that the compound should remain perfectly white after exposure to heat: it should also endure a very high temperature without fusing, and at the same time acquire a semi-vitreous texture, and a peculiar degree of translucency and toughness. These qualities are united in some of the Oriental porcelain, or *China*, and in some of the old Dresden; but they are rarely found coexistent in that of modern European manufacture. Some of the French and English porcelain, especially that made at Sèvres and Worcester, is extremely white, and duly translucent; but it is more apt to crack by sudden changes of temperature; more brittle, and consequently requires to be formed into thicker and heavier vessels; and more fusible than the finest porcelains of Japan and China.

The colours employed in painting porcelain are the same metallic oxides used for colouring glass, and in all the more delicate patterns they are laid on with a camel's hair pencil, and generally previously mixed with a little oil of turpentine. Where several colours are used, they often require various temperatures for their perfection; in this case those that bear the highest heat are first applied, and subsequently those which are brought out at lower temperatures. This art of painting on porcelain, or *in enamel*, is very delicate: much experience and skill are required in it, and with every care there are frequent failures; hence it is attended with considerable expense. The gilding of porcelain is generally performed by applying finely divided gold mixed with gum-water and borax; upon the application of heat the gum burns off, and the borax vitrifying upon the surface causes the gold firmly to adhere: it is afterwards burnished.

In the manufacture of various kinds of pottery employed in the chemical laboratory, and especially in regard to *crucibles*, many difficulties occur; and many requisites are necessary, which cannot be united in the same vessel. To the late Mr. Wedgwood we are indebted for vast improvements in this as well as in other branches of the art. Crucibles composed of one part of pure clay mixed with about three parts of coarse and pure sand, slowly dried and annealed, resist a very high temperature without fusion, and generally retain metallic substances; but where the metals are suffered to oxidise, there are few which do not act upon any earthen vessel, and some cause its rapid fusion, as the oxides of lead, bismuth, &c. Where saline fluxes are used, the best crucibles will always suffer; but platinum may often be employed in these cases, and the chemist is thus enabled to combat many difficulties which were nearly insurmountable before this metal was thus applied. Whenever silica and alumina are blended, as in the mixture of clay and sand, the compound softens, and the vessel loses its shape when exposed to a long-continued white heat, and this is the case with the *Hessian* crucibles: consequently, the most refractory of all vessels are those made entirely of clay, coarsely powdered burnt clay being used as a substitute for the sand. Such a compound resists the action of saline fluxes longer than any other, and is therefore used for the pots in glass furnaces. A Hessian crucible lined with purer clay is rendered much more retentive; and a thin china cup, or other dense porcelain, resists the action of saline matters in fusion for a considerable time. Plumbago is a very good material for crucibles, and applicable to many purposes; when mixed with clay it forms a compound not easily fusible, and is protected from the action of the air at high temperatures: it is well calculated for small table furnaces. [EARTHENWARE; GLASS.]

Pouch (Fr. poche). In Military equipment, a leather case, lined with tin, to carry a soldier's ammunition.

Poudrette (Fr.). A manure composed of night soil mixed up with clay, dried and formed into cakes.

Poulp (Fr. poulpe). The generic name of the eight-footed dibranchiate Cephalopods (*Octopi*), which have a double alternate row of suckers on each foot.

Poultry (Fr. poule, Lat. pullus, Gr. πῶλος, the *foal* or young of animals). Different kinds of birds reared for the production of eggs and feathers, and for the use of their bodies as animal food. The domestic poultry in common use in Britain are the common domestic fowls, or cock and hen, the turkey, the duck, and the goose; to which may be added, as occasionally reared, the guinea fowl and the peacock. The most generally useful kind of poultry is the common domestic fowl, which, though a native of India, accompanies man through all climates, but which produces an abundance of eggs only when well fed and warmly lodged. All poultry houses, therefore, when not built adjoining an apartment in which fire is kept, or over a stable or cowhouse, where they may benefit by the heat generated by the larger animals, ought to be furnished with flues, or some other means of generating heat artificially during winter and spring. Without some mode of effecting this, poultry will seldom yield a good supply of eggs in cold weather, particularly in the colder parts of Britain. On this account, in Scotland, the common hen is allowed to roost in the same room in which the cottager lives; and the poultry-house of the small farmer is a loft either over his kitchen, or over his cow-house. In the management of poultry it is essential that they should have not only the necessary food and warmth, but also ample space for exercise. This space should always contain living plants of various kinds, and some gravelly, calcareous, or sandy soil; because worms, snails, and insects, as well as grass and herbage occasionally, form a part of the food of poultry; and sand or gravel is swallowed by them for the purpose of promoting digestion. Hence, no healthy poultry can ever be reared in towns, however much the natural food may be imitated by the supply of animal matters, herbage, and sand: the want of exercise in poultry so circumstanced will soon become evident from the appearance of the fowls, and from the soft shell of their eggs.

Some breeds seem, however, to require less liberty than others. We add a list of the breeds now known and cultivated in this country.—*Grey, Silver Grey, Speckled, and White Dorkings*—Excellent farmyard fowls. Good layers and sitters. Very good mothers. Not calculated for confinement. Unequalled as a table or market fowl. Very large. *Brahma Pootra*—Excellent layer, perfect sitter, and mother; so hardy it may be hatched and reared in any weather. Two varieties: one pencilled; the other white, with black flight and tail, and striped hackle. These birds bear any confinement. As winter layers the Brahma Pootras excel all other birds. *Spanish*—Very handsome black birds. Lay larger eggs than any other breed, and in great numbers. Thrive in any locality, however confined. Do not sit. Their colour suited for any atmosphere. *Cochin Chinese*—Seem to prefer a very limited space; capital layers; very hardy; seldom or never out of condition. Good sitters. Chickens very easily reared. Pullets hatched in spring are good winter layers. *Crevecœurs*—Hardy birds, and most profitable layers, producing an unusual number of very large eggs during the autumn when most birds are deep in moult. They are excellent table birds, do not sit, and thrive well in stable yards, small homesteads, and confined places. *La Flèche*—The finest fowl known in France, a very handsome upstanding bird of jet black plumage; the comb is in the form of two upright horns. A delicious table fowl of great size; an excellent layer. Thrives well on a good run, or farm yard. *Game*—Hardy and capital birds. Good layers, good mothers, excellent for the table. Will do well in confinement. Suited to every soil and climate. Varieties: Black and Brown-breasted Reds, Duck-wings, Black, White and Piles. *Hamburgs*—Very handsome birds, unusually good layers, bear moderate confinement well. Do not sit. *Polands*—Remarkably handsome birds, very good layers, but non-sitters. Fit for the paddock, but not for confinement. Varieties: Golden and Silver Spangled, and Black with white top-knots. *Houdans*—A recent introduction from France, where they are considered a very good table fowl. They are large, of a speckled colour, with top-knots. *Malay*—Hardy and prolific birds, will do well where all others fail; good layers, and well adapted for towns.

Poultry-houses. Structures in which poultry are kept in the night time; they should be so arranged that each kind of bird shall be separately lodged, and that all shall have access to an ample field, containing a pond and a heap of gravel. [POULTRY.]

Pounce (Fr. ponce, from Ital. pomice, Lat. pumex, *a pumice stone*: Wedgwood). A powder to prevent ink from spreading upon paper, after erasures: it is either sandarach (resin of the juniper) in powder, or the powdered bone of the cuttle-fish. The term *pounce* is also applied to coloured powders used by pattern drawers for sprinkling over pricked papers.

Pound (Ger. pfund; Lat. pondo, *in weight*). A measure of weight. In England two different pounds are used; the *pound avoirdupois*, and the *pound troy*. The pound avoirdupois weighs 7,000 grains troy, and the pound troy 5,760 grains. The former is divided into 16 ounces, and the latter into 12. [WEIGHT.] Pound is also a denomination of money; the pound sterling being equal in value to 20 shillings, or 240 pence. Anciently 240 pence were equivalent to a pound of silver; hence the origin of the term.

Poundage. An ancient ad valorem duty of five per cent., payable on all foreign goods imported into the kingdom, and occasionally on exports. It has been held that these duties were paid, time out of mind, on the plea that the king was by these means compensated for the cost of keeping up harbours and havens, and of defending merchants from pirates, and that the payment is part of the common law. This tax is, however, known to have had its origin in an Act of the first Parliament of Edward I. Poundage was at first granted for a limited period, then for the life of the king, generally among the Acts of the monarch's first parliament. The parliaments of Charles I. refused to make the grant, but those of his three legal successors were more complaisant. The need of providing larger means for the public service led the parliaments of Anne to mortgage this custom for the payment of the public debt, and poundage has been lost in the general imposition of customs duties.

Poupart's Ligament. The tendinous attachment of the external oblique muscle of the abdomen to the superior and anterior spinous process of the os ilium and os pubis.

Pourpoint (Fr.). In ancient armour, the quilted coat, worn next the body, otherwise often known as the gambeson or doublet. Sometimes an outer pourpoint was worn between the surcoat and the body armour.

Pourpresture or **Purpresture.** In Law, an ancient term to denote anything done to the injury of the king's tenants, by way of nuisance or hurt to the king's highways or demesnes, by enclosing, &c. Pourpresture may also be by tenant against lord of the fee, or by one neighbour against another.

Poursuivant. [PURSUIVANT.]

Powder Hose. A tube of strong linen, about an inch in diameter, filled with powder, and used for firing military mines.

Power. In Algebra, this word denotes the product arising from the continued multiplication of equal numbers or quantities. Thus a, aa, aaa, which for brevity are written a, a^2, a^3, denote respectively the first, second, and third powers of a. The small numbers in the above abbreviated expressions are termed the *indices* or *exponents* of the several powers. Powers of the same quantity are multiplied by adding, and divided by subtracting their exponents. Assuming the relation $a^m a^n = a^{m+n}$ to hold for all values of m and n, we are led to the conception of *negative* and *fractional powers*. The first are the reciprocals of the corresponding positive powers, thus $a^{-2} = \frac{1}{a^2}$; and the second are roots of powers or powers of roots; thus $a^{\frac{2}{3}} = \sqrt[3]{a^2} = (\sqrt[3]{a})^2$. Since $a^m a^0 = a^{m+0} = a^m$, we learn that a^0 must be regarded as a general symbol for unity whatever value a may have.

POWER. In Law, an authority given to a person enabling him to do some act with respect to property of which he is not the owner or not the absolute owner. Thus, for example, in an ordinary strict settlement of real property, it is usual to insert powers for the tenant for life to grant leases and to give a jointure to his wife or portions for his children, and for trustees to sell the property, or manage it during minorities and the like; and corresponding powers of investment, of appointing funds to particular children, of advancement and maintenance of minors, &c., are usually inserted in settlements of personal property. Again, in a mortgage the mortgagee has usually a power of sale to enable him to realise his security. Powers for the most part are strictly construed, and the courts are very vigilant in preventing their use for any purpose but that for which in the particular case they were intended; as, for instance, if a man having a power to appoint a fund among his children appoints it to one of them upon an understanding that he himself is to derive some private advantage, the appointment will be bad. There are many technical divisions of powers as they arise at common law, or under the Statute of Uses or some other statute, or are mere equitable authorities, affecting property vested in trustees or mortgagees, and the learning with respect to them forms one of the principal branches of Property Law. The introduction of lengthy powers is one of the principal causes of the bulk of English legal instruments, but this again arises from the great unwillingness always shown by the courts to extend by implication the authority over property of one not absolute owner of it to any cases not expressly provided for, so that it becomes necessary to provide by an appropriate clause for every occasion which is considered at all likely to arise. Some efforts have been recently made by the legislature (stats. 19 & 20 Vict. c. 120, 23 & 24 Vict. c. 145, &c.) to provide that certain powers should in specified cases be implied as of course.

POWER. In Mechanics, this term denotes a force which being applied to a machine tends to produce motion. A *mechanical power* denotes one of the six simple machines; viz. the *lever*, the *inclined plane*, the *screw*, the *wheel and axle*, the *wedge*, and the *pulley*.

Power of Attorney. In Law, an instrument by which a party empowers another to perform certain acts for him, either generally, or for a particular purpose; such as to accept and negotiate letters of exchange, to receive dividends, &c. An instrument by which a party authorises his attorney to appear and plead for him is termed a WARRANT OF ATTORNEY.

Powers, Great, of Europe. In the language of modern diplomacy, Great Britain, France, Austria, Russia, and Prussia, are so called.

Power-loom. [WEAVING.]

Poyning's Law, otherwise called the **Statute of Drogheda.** An enactment of the Irish parliament in 1495. It contains a variety of provisions to restrain the lawlessness of the Anglo-Irish within the pale (for to no others could it immediately extend), and to confirm the royal sovereignty. The article by which it is

principally known provided that no parliament should in future be holden in Ireland till the king's lieutenant had certified to the king under the great seal the causes and considerations, and all such acts as ought to be passed thereon, and such be affirmed by the king and his council, and his license to hold a parliament be obtained. Any parliament holden contrary to this form and provision should be deemed void. Thus by securing the initiative power to the English council, a bridle was placed in the mouth of every Irish parliament. (Hallam.) A practice, however, grew up afterwards of framing bills in either house of the Irish parliament under the denomination of *heads for a bill or bills*, by which the provisions of Poyning's law were in some measure evaded. (Goldwin Smith, *Irish History and Character*.)

Pozzuolana. Fine volcanic ashes mixed with about one fifth part of oxide of iron and a little lime form a natural hydraulic cement, which hardens under water and answers the purpose of Roman cement. It is much used in Italy instead of mortar, and has received its name owing to the fact of its being shipped from Pozzuoli. [CEMENTS; MORTAR.]

Praam. A sort of lighter used in Holland and the Baltic.

Practical Geology. [ECONOMIC GEOLOGY.]

Practice (Fr. pratique, Span. practica, from Gr. πρακτικός). A rule in Arithmetic for expeditiously solving questions in proportion; or, rather, for abridging the operation of multiplying quantities expressed in different denominations, as pounds, shillings, and pence; yards, feet, and inches, &c.

Præcordia (Lat. from præ, and cor, *the heart*). The fore part of the chest.

Præfect (Lat. præfectus). The title of several Roman functionaries. Of these the most important were: (1) præfectus urbi, the præfect or warden of the city, originally called Custos Urbis. This officer possessed the imperium in the city during the absence of the consuls; but the institution of the office of prætor urbanus left no room for his functions. The conservative spirit of the Romans, however, still induced them to appoint a præfectus urbi for the time during which the consuls were absent from Rome to celebrate the feriæ Latinæ; but this officer had no right of convoking or of speaking in the senate, and it became a nominal distinction conferred on young men of illustrious families. The office to which Augustus appointed Mæcenas was very different from this, being a regular and permanent magistracy invested with all necessary powers for maintaining peace and order in the city. Under this præfect was a force of milites stationarii, or city police; and the powers of the office were gradually so far extended that at last there was no appeal from his sentence except to the princeps himself, whereas the præfectus urbi was empowered to hear appeals against any other city magistrates, and even against the governors of provinces. (2) The prætorian præfect, præfectus prætorio, commanded the PRÆTORIAN COHORTS. This officer, after the appointment of Sejanus by Tiberius, stood to the emperors in a relation not unlike that of the magister equitum to the DICTATOR, or of a Turkish vizir to the sultan. This office was not always held by military men, Ulpian, Papinian, and other lawyers having been numbered among the prætorian præfects. (3) The office of præfectus annonæ, or præfect of the provinces, was an extraordinary magistracy, filled only during times of scarcity. But after the fall of the republic, Augustus made the office permanent. In addition to these there were (4) the præfectus aquarum, an officer charged with the regulation of the water supply for the city; (5) the præfectus ærarii [ÆRARIUM], and (6) the præfectus vigilum, or commander of the Roman night-watch; with some others.

The title of præfect was also given to the governor of Egypt, the governors of the other imperial provinces being called legati Cæsaris, selected either from persons who had been consuls or prætors, or from the senators, while the governor of Egypt was of equestrian rank.

Præfloration (Lat. præfloreo, *to blossom before the time*). In Botany, the arrangement of the parts of the flower before expansion.

Præfoliation (Lat. præ, *before*; folium, *a leaf*). In Botany, the arrangement of the leaves in a leaf-bud.

Præmolar (Lat. præ, *before*, and molaris, *grinding tooth*). In Anatomy, the name of those permanent teeth in the Diphyodont mammals that displace and succeed the deciduous teeth vertically: they are situated before the molars; and, being in many cases of more simple structure, they have been termed *false molars*, and in Human Anatomy *bicuspides*. The præmolars never exceed four in number on each side of both jaws.

Præmonstratensians. [PREMONSTRATENSIANS.]

Præmorse (Lat. præmorsus, part. of præmordeo, *to bite*). In Botany, a term applied to parts which terminate abruptly in a rugged irregular manner, as if bitten off.

Præmunire. In Law, a name given to a species of offence, in the nature of a contempt, against the king and his government. The name is derived from the words *præmoneri*, or *præmuniri facias*, which are used in the begining of the writ preparatory to the prosecution of the offence: 'Cause A. B. to be forewarned that he appear before us,' &c. The first statute of præmunire was passed in the reign of Edward I. to restrain the encroachments of the Romish clergy: and several subsequent statutes before the Reformation have extended the number of penal acts under this title. By still later statutes, acts of a very miscellaneous character have been rendered liable to the penalties of præmunire, as a refusal to take the oaths of allegiance and supremacy, &c.

Prænomen. [COGNOMEN; NAME.]

Præraphaelite. In Painting, an illogical term lately introduced to signify a modern revival, with certain modifications, of the highly finished but crude and tasteless sentimental art of the fifteenth century, before the time of Raphael; an art which is characterised more by its defects than by its perfections. Its character is referred to in the Italian expression QUATTROCENTISMO.

Prætexta. [TOGA.]

Prætor. The Roman consuls were originally known by this name (Cic. *De Leg.* iii. 3), which simply signified priority. According to Livy, the office specially distinguished by this name was instituted B.C. 366, when, after the Licinian Rogations, L. Sextius had been elected the first plebeian consul. The patres refused to ratify his election, unless a prætor and two curule ædiles were elected out of their own body. (Sir G. C. Lewis *On the Credibility of Early Roman History*, vol. ii. 377, 396.) Part of the functions of the prætor was to administer justice between Roman citizens; in B. C. 246 another prætor, called *peregrinus*, was appointed to judge in suits between Roman citizens and foreigners; after which time the former prætor received the epithet *urbanus*. The two prætors determined their offices by lot.

So long as the Roman empire was confined to Italy, the number of prætors did not exceed two; but on the reduction of Sicily and Sardinia to the form of provinces, two more were added to govern them, and again two more were created on the subjection of Spain to the Roman yoke. Under the emperors the powers of the prætors were reduced, but the office itself existed to a late period of the empire. (Niebuhr's *Roman History*.)

Prætorian Cohorts. A body of troops among the Romans, distinguished from the rest of the army by double pay and superior privileges, first instituted by Augustus, and called by that name in imitation of the select band which attended a Roman general in battle. At their first institution the cohorts were nine in number, three being stationed at Rome, and the rest in the adjacent towns of Italy; they consisted of Italian soldiers only. Tiberius assembled them all at Rome, and placed them in a permanent camp; a measure which, while it answered the purpose of keeping the citizens in awe, proved dangerous and sometimes destructive to his successors. The emperor Severus disarmed the old guards, and established the prætorian cohorts on a new footing, increasing their number, and filling them entirely with troops draughted from the armies of the northern frontier. The command of these troops was vested in an officer called the prætorian prefect, who, as the government gradually degenerated into a military despotism, rose from the station of simple captain of the guards not only to be the head of the army, but of the provinces, and even of the law. In every department of administration he represented the person and exercised the authority of the emperor. The prætorian bands were deprived of all their privileges by Diocletian, who replaced them by other troops, and they were finally abolished by Constantine.

Prætorium (Lat.). That part of a Roman camp in which the general's tent stood, and where he took the auspices. It was raised a few feet above the level of the rest of the camp. Of the four gates of the Roman camp, that which lay next the enemy was called the *prætorian* gate.

Pragmatic Sanction, more correctly **Pragmatic Rescript.** A term of which the use seems to have originated in the Byzantine empire, signifying a public and solemn constitution or decree pronounced by a prince; distinguished from the simple rescript, which was a declaration of law in answer to a question propounded on behalf of an individual. In European history several important treaties are called by the name *Pragmatic Sanction*; among which the principal are: 1. The ordinance of Charles VII. of France in 1438, which constituted the foundation of the liberties of the Gallican church. 2. Charles VI., emperor of Germany, being without male descendants, endeavoured by an instrument termed the Pragmatic Sanction to secure the succession to his female heirs; which caused the Bavarian war of succession, 1740. 3. The law of succession to the kingdom of Naples, when ceded by Charles II. of Spain, in 1759, to his third son and his posterity.

Prairie (Fr.). A term in common use for the vast plains or savannahs of the Mississippi and Missouri. [SAVANNAHS.]

Prakrit. By this name are known certain dialects in India, which acquired greater prominence as the older Sanscrit passed gradually out of use. These dialects 'first assumed a literary position in the Sanscrit plays, where female characters both high and low are introduced as speaking Prakrit, instead of the Sanscrit employed by kings, noblemen, and priests.' From the Prakrit the modern vernaculars of India have branched off, just as the modern Romance languages have sprung immediately from the old Italian dialects, which preserved the power of growth denied to the Latin as to all other literary languages. (Max Müller, *Lect. on Language*, 2nd series, p. 38.)

Pramantha. [PROMETHEUS.]

Prangos (its Tartar name). A Persian genus of Umbelliferous herbs, one of which, the Hay plant of Thibet, was some years ago greatly lauded as a forage plant, various attempts being made to introduce it among the agricultural plants of this country, but without success. Its high reputation appears to have been undeserved, for although extremely valuable in the cold and arid regions of Thibet, where it is indigenous, and where forage of a better quality is not obtainable, it is not so much esteemed in Kashmir and other more fertile countries, where grass-pasture exists. It was first discovered by Mr. Moorcroft during his travels in Thibet, and was spoken of by him as being extensively employed as winter

fodder for sheep, goats, and frequently for neat cattle, producing fatness in a very short time, and destroying the liver-fluke, so fatal to sheep. The late Dr. Royle was of opinion that this plant was probably the kind of *Silphium* mentioned by Arrian in his account of the wars of Alexander. 'In this part of the Caucasus' (the modern Hindu Koosh) 'nothing grows except pines and silphium; but the country was populous, and fed many sheep and cattle, for the sheep are very fond of the silphium. If a sheep should perceive the silphium from a distance, it runs to it and feeds on the flower, and digs up the root and eats that also.'

Prase or **Prasem** (Gr. πράσον, *a leek*). A dark leek-green variety of Quartz, the colour of which is caused by an admixture of Hornblende. It is found at the iron mines of Breitenbrunn in Saxony, in the Harz, and in fine crystals at the Cedar Mountain in South Africa.

Praseolite (Gr. πρασον, and λίθος, stone; from its colour). An altered form of Iolite, which occurs in rounded rhombic prisms with four, six, eight, or twelve sides, having a basal cleavage and a lamellar structure, at Bräkke, near Brevig, in Norway, in quartz-veins traversing gneiss.

Prasochrome. Carbonate of lime coloured by oxide of chrome, forming a dull green incrustation on the island of Scyro, in the Grecian Archipelago.

Pratique (Fr.). A limited quarantine which the captain of a vessel is considered to have performed when he has convinced the authorities of a port that his ship is free from infectious disease.

Praxeans. An Asiatic sect of the second century; so called from their founder, Praxeas. The distinguishing characteristics of this sect were their denial of plurality of Persons in the Godhead, and their belief that it was the Father himself who suffered on the cross. The Monarchians, Sabellians, and Patripassians adopted these sentiments.

Pre-Adamites (Lat. *prior to Adam*). The legendary traditions of the East speak of nations and empires subsisting before the creation of Adam, and of a line of kings who ruled over them. The subject has been taken up, in modern times, by Isaac Lapeyrère, in his work *Præadamitæ*, 1655, wherein he endeavours to show, by deduction from Romans v. 12, &c., that Adam was the ancestor of the Jews only, the Gentiles being descended from a long anterior creation.

Pre-emption, Right of (Lat. præ, *before*, and emptio, *a purchasing*). It is sometimes directed by an Act of Parliament or other legal instrument that property for sale shall be offered in the first instance to some particular person, in which case he is said to have an option or right of pre-emption.

Pre-existence. In Philosophy, the existence of anything before another; commonly used for the existence of the human soul, in some former condition, before it became connected with its present body. It was the doctrine of the Pythagorean school, and connected with their peculiar tenet of METEMPSYCHOSIS. It was also the doctrine of Plato, who lays much stress on the rapidity of learning in early childhood, which he explains as an effort of reminiscence (ἀνάμνησις), not acquisition. Others have enlisted into the service those peculiar sensations which are sometimes raised by sights or sounds though seen or heard, as our reason would persuade us, for the first time, as if we are conscious of some prior familiarity with them. This poetical, rather than philosophical view of the subject, is beautifully illustrated in a well-known ode of Wordsworth.

Preamble (Lat. præambulare, *to go before*). The introduction or prefatory part of an Act of Parliament, explaining the reasons for its being passed. In railway bills, and other private bills of a similar nature, the preamble always contains distinct statements that it would be expedient that the objects of the bill should be effected, and that such purposes cannot be effected without the authority of parliament; and when any such bill is referred to a committee of either house, the first duty cast on its promoters is to prove the preamble, i.e. to establish the truth of these statements. After the promoters and opponents of the bill and their witnesses have been heard upon these points, the question is put to the committee 'that the preamble has been proved,' which is resolved in the affirmative or negative as the case may be, and the result of this question decides whether the bill is to proceed further or not. In Public General Acts the preamble is of little importance, and is now usually much curtailed or altogether omitted.

Prebend (Lat. præbenda). The share of the estate of a cathedral or collegiate church received by a prebendary. To all such churches there are several prebendaries attached, who reside and officiate in rotation.

Precedency (Lat. precedo, *I go first*). The relative rank of men and women in the etiquette of society; strictly it means the order in which they follow one another in a state procession, which it is part of the Office of Heralds' duty to ascertain and preserve. The following are the degrees of precedency commonly recognised in England among men: 1. The sovereign. 2. The prince of Wales. 3. The queen's consort. 4. The queen dowager. 5. The princes of the blood according to seniority. 6. The sovereign's uncles. 7. Cousins of the sovereign. 8. Husbands of princesses. 9. The archbishop of Canterbury. 10. The lord high chancellor. 11. The archbishop of York. 12. Lord high treasurer. 13. Lord president of the privy council. 14. Lord privy seal. 15. Lord high constable. 16. Earl marshal. 17. Lord high admiral. 18. Lord steward of the household. 19. Lord chamberlain of the household. (The last five, however, take precedence only of all their degree: i.e. if dukes, they precede all dukes; if marquises, all mar-

quises, &c.) 20. Dukes. 21. Marquises. 22. Dukes' eldest sons. 23. Earls. 24. Marquises' eldest sons. 25. Dukes' younger sons. 26. Viscounts. 27. Earls' eldest sons. 28. Marquises' younger sons. 29, 30, 31. The bishops of London, Durham, and Winchester. 32. Other bishops, according to priority of consecration. 33. Barons. 34. Speaker of the House of Commons. 35. Viscounts' eldest sons. 36. Earls' younger sons. 37. Barons' eldest sons. 38. Knights of the Garter. 39. Privy councillors. 40. Chancellor of the Exchequer. 41. Chancellor of the duchy of Lancaster. 42. Lord chief justice of Q.B. 43. Master of the Rolls. 44. Lord chief justice of C.P. 45. Lord chief baron of the Exchequer. 46. Lords justices of appeal, according to priority of appointment. 47. Vice-chancellors, ditto. 48. Puisne judges and barons of superior courts, and judge of Probate Court, ditto. 49. Knights bannerets made by the sovereign in person. 50. Viscounts' younger sons. 51. Barons' younger sons. 52. Baronets. 53. Bannerets not made by the sovereign in person. 54. Knights grand cross of the Bath. 55. Knights grand crosses of St. Michael and St. George. 56. Knights commanders of the Bath. 57. Knights commanders of St. Michael and St. George. 58. Knights bachelors. 59. Companions of the Bath. 60. Companions of St. Michael and St. George. 61. Eldest sons of the younger sons of peers. 62. Baronets' eldest sons. 63. Knights of the Garter's eldest sons. 64. Bannerets' eldest sons. 65. Knights of the Bath's eldest sons. 66. Knights' eldest sons. 67. Baronets' younger sons. 68. Esquires of the king's body. 69. Gentlemen of the privy chamber. 70. Esquires of the knights of the Bath. 71. Esquires by creation. 72. Esquires by office or commission. 73. Younger sons of knights of the Garter. 74. Younger sons of bannerets. 75. Younger sons of knights of the Bath. 76. Younger sons of knights bachelors. 77. Gentlemen entitled to bear arms. 78. Clergymen not dignitaries. 79. Barristers at law. 80. Officers in the army and navy not esquires by commission. 81. Citizens, burgesses, &c.

Precedents. In Law, precedents are decided cases, followed as authorities in courts of justice. Precedents, strictly speaking, are binding on tribunals only when they are in the shape of actual judicial decisions of the point in question. What English lawyers term an extrajudicial opinion—i.e. the opinion of a judge pronounced where it was not called for to decide the issue—can have authority only from the character of the individual judge, and not as a precedent. When the principles of equity were as yet unsettled, it was held by many that precedents were inapplicable in that branch of law; as its very name seemed to imply that each case should be governed by the judge's opinion of its individual merits. But Lord Keeper Bridgman, among others, seriously refuted this supposition; and precedents have long been of as much authority in courts of equity as in those of common law. A form of an instrument or a pleading, from which others corresponding in circumstances may be copied, is also termed a *precedent*.

Precentor (Lat. præcentor). The leader of a choir. In most cathedrals of old foundation in England the precentor ranked next to the dean. In the more modern foundations the precentor is usually a minor canon.

Preceptories. In the Middle Ages, a kind of benefices so called as being held by the more eminent Knights Templars, whom the grand master created and styled *Præceptores Templi*. Of these preceptories, sixteen are recorded as belonging to the Templars in England (*Mon. Ang.*); but it is thought by some writers that these places were merely cells, subordinate to their head-quarters, the Temple in London. [COMMANDERY.]

Precession of the Equinoxes. A term used in Astronomy to denote a small annual variation in the position of the line in which the planes of the ecliptic and equator intersect each other, in consequence of which the sun returns to the same equinoctial point before completing his apparent revolution with respect to the fixed stars.

The longitude of a star is counted on the ecliptic eastward from the first point of Aries, or the vernal equinox. If the line of the equinoxes, therefore, maintained always the same position with respect to the celestial sphere, the longitude of the stars would be invariable. But on comparing the actual state of the heavens with the observations recorded by ancient astronomers, it is found that the longitudes of all the stars have considerably increased, and all to the same degree; so that the celestial sphere appears to turn round the axis of the ecliptic with a slow motion from west to east, or in the same direction as the sun in his annual revolution. The phenomena, however, will be in all respects the same, if, instead of supposing the whole firmament to advance in the order of the signs, we suppose the axis of the earth's equator to have a slow motion about the axis of the ecliptic in the opposite direction. This will give to the line of intersection of the two planes (which is the line of the equinoxes) a retrograde motion from east to west, in consequence of which the sun, whose motion is from west to east, arrives at the equinoctial points sooner than if they remained at rest; and therefore the equinoxes, and the seasons which depend on them, come round before the sun has completed an entire circuit of the sphere. On this account the motion has been called the *precession of the equinoxes*.

Although the existence of the precessional motion of the equinoctial points was known at an early period in the history of astronomy, the imperfection of instruments prior to the sixteenth century did not permit of observations being made with sufficient accuracy to determine its precise rate, which must therefore be deduced from comparisons of the longitude of the same star calculated from modern

observations; but, on account of the extreme slowness of the motion, the determination must still be liable to some uncertainty, unless a considerable interval of time has elapsed between the epochs of observation. According to Bradley's observations the longitude of the star *Spica Virginis*, at the beginning of the year 1760, was 200·4944°. At the beginning of 1802 Maskelyne found the longitude of the same star to be 201·0781°. The difference is 0·5837° in forty-two years, which gives 50·03″ in a year. The comparison of a great number of observations on different stars gives 50·1″ for the annual precession. According to this estimate, the equinoctial points retrograde on the ecliptic at the rate of one degree in 71·6 years, and therefore will require a period of about 25,800 years to make a complete revolution. The constant of precession for the year 1868 is 50·2565″.

The physical cause of the precession of the equinoxes is the combined action of the sun and moon on the mass of matter accumulated about the earth's equator, and forming the excess of the terrestrial spheroid above its inscribed sphere. The matter of this spheroidal shell, in reference to the effect of the solar attraction on it, may be regarded as forming a ring about the earth in the plane of the equator. Now the solar force, acting on the part of the ring which is above the ecliptic, may at every point be resolved into two parts, one parallel to the plane of the equator, and the other perpendicular to it; and the resultant of all the latter forces must be a force tending to impress on the ring a motion round the intersection of its plane with the ecliptic. The same thing holds true of the other half of the ring which is under the ecliptic. If the earth, therefore, had no motion of rotation, the plane of the equator would turn round the line of its intersection with the ecliptic until it coincided with the latter plane. But while the equator has this tendency to revolve about an axis in its plane, it has also a rotatory motion about an axis perpendicular to its plane; it will, therefore, according to a well-known theorem in mechanics, revolve not on either of these axes, but on one which divides the angle between them, so that the sine of its angular distance from each axis is in the inverse ratio of the angular velocity round that axis. [ROTATION.]

The motion now described may be assimilated to that of a top put into rapid motion, with its axis inclined to the horizon. In this position the axis of the top slowly revolves about the vertical drawn from the point on which it rests, describing the surface of a cone; and any section of the top perpendicular to the axis, if produced to meet the horizon, will at every instant intersect that plane in a new line; and the line of intersection will revolve with a motion corresponding to that of the axis in the direction opposite to that of the rotation.

The attraction of the moon on the spheroidal shell produces a similar effect to that of the sun, and in a still greater degree, in the ratio of about 5 to 2. It is easy to see that the effect of both those bodies in displacing the equator of the terrestrial spheroid must vary with their position in reference to it; for if they moved in the plane of the equator, there would evidently be no displacement, and their power to produce it is greatest when the earth is in such a position that the inclination of the equator to the ecliptic, or to the plane of the lunar orbit, is a maximum. This inequality of action gives rise to another highly important astronomical phenomenon; namely, an apparent vibratory motion of the equator, which Bradley (who first discovered its cause and period) significantly denominated the *nutation of the earth's axis*. [NUTATION.]

In consequence of the precession of the equinoxes the sun's place among the zodiacal constellations, at any given season of the year, is now greatly different from what it was in remote ages. Some time before the age of Hipparchus the first points of Aries and Libra corresponded to the vernal and autumnal equinoxes, and those of Cancer and Capricorn to the summer and winter solstices. These points have now receded 30° from the constellations to which they then corresponded. The vernal equinox now happens when the sun is in Pisces, the summer solstice when he is in Gemini, the autumnal equinox when he is in Virgo, and the winter solstice when he is in Sagittarius. Astronomers, however, still employ the term *the first point of Aries* to denote the position of the vernal equinox. On this account the *signs of the zodiac*, or ecliptic, which are fixed in respect of the equinoctial points, must be carefully distinguished from the *constellations*, which are movable with respect to those points. (Airy's *Mathematical Tracts*; *Encyc. Brit.* art. 'Precession;' Woodhouse's *Physical Astronomy*; La Place, *Mécanique Céleste*; Poisson, 'Sur le Mouvement de la Terre autour de son Centre de Gravité,' in the *Mém. de l'Acad. des Sciences de Paris*, tom. vii. 1829.)

Precious Garnet. [GARNET; PYROPE.]

Precious Metals, The. For reasons given in the article MONEY, all civilised nations have accepted gold and silver, or both, as media of exchange, or a common measure of values.

Cost of the Precious Metals.—When any country is itself a producer of these commodities, the charge at which they are procured, and their consequent value, depends as in other articles on the cost of their production; and if they are produced by mining, the land in which they are mined will pay a rent, in just the same way as a copper, lead, or coal mine pays a rent, if they should be found in such abundance as to be procured at less cost than that at which they can be imported (the produce not being sufficient for the wants of the community). A large portion of the silver brought into the market of this country is of home produce, being found in lead, and easily refined by a simple but ingenious method known as *Pattison's process*. The amount of gold, however, found in the British Isles is quite

unimportant by the side of that which is imported.

If, however, the precious metals are imported, the cost at which they are procured is measured by the cost of the commodities with which they are exchanged. They may cost much or little to the producer; but this will make no difference to the purchaser in foreign countries, the sole gauge by which he will measure their value being found in the charge at which he is to procure goods to exchange against them. Hence, if the gold and silver in the world were suddenly increased at little cost to its possessors, or if it were to accumulate without decay or loss, prices would inevitably be affected by a general rise, or, in other words, the price of gold and silver as measured by other commodities would fall. The former of these phenomena took place in the middle of the sixteenth century, though much more slowly than is commonly supposed; the latter would occur in this country, if it were not the case that gold and silver are as rapidly exported as they are imported, the course of trade in the precious metals using this country only as a reservoir from which supplies are derived to other parts of the world. It is plain, also, as gold and silver are imported into non-producing countries in exchange for commodities, that those countries which supply articles of the highest value at the least cost of production, and are nearest to the mines, will get the precious metals at the cheapest rate, i.e. prices would naturally be highest in such countries; if they are not, it is because the same cause which gives a greater purchasing power over gold and silver—the efficiency, namely, of labour—enables the possessor of money to purchase commodities at lower rates, and of course to procure, as he does the metals themselves, all other imports at cheaper rates.

Distribution of the Precious Metals.—Mr. Ricardo has said, 'that gold and silver having been chosen for the genera' medium of circulation, they are by the competition of commerce, distributed in such proportions among the different countries of the world, as to accommodate themselves to the natural traffic which would take place if no such metals existed and the trade between countries were purely a trade of barter.' This position, which is perfectly sound, shows, in the first place, how ill judged are all attempts to control or direct the import and export of the precious metals, and how, in order that they should be distributed at all, it was inevitable that the precautions taken in past times should be defeated; in the next, that, as far as trade is concerned, no country ever takes more or less of the precious metals than is necessary for the wants of its commerce, and for its reserve against contingencies; and, next, that when the course of trade with any country necessitates a large and continuous exportation of the precious metals, the absorption is not for purposes of currency, but for the arts, for personal display, or for hoarding. The machinery by which this distribution takes place is by the course of trade, and especially by the fluctuations of the foreign exchanges.

Sources of the Precious Metals.—No register of the imports of the precious metals was taken at the custom-house before November, 1857, i.e. subsequent to the time in which the Californian and Australian discoveries were made. Between 1858 and 1863, the two most important sources of gold bullion and specie have been Australia and the United States, the large exports from the latter country being relative not only to the mines, but consequent upon the state of the exchange during the war, and the forced paper circulation. *The quantity supplied from the mines is steadily decreasing.* After the supply from the New World, the largest contributions are from Russia. On the other hand, the supplies of foreign silver come chiefly from Mexico and France, from the former in the shape of bullion, from the latter in coin, the process by which gold has been substituted for silver currency in France not having been yet completed. Again, the largest amount of gold bullion and specie passes to France, of silver bullion and specie to Egypt, for China and India, coin being absorbed in China, bullion in India, this exportation of specie to the latter locality having been enormously increased of late years by the necessity of purchasing the inferior Indian cottons in large quantities at greatly enhanced rates. There cannot be a doubt that this vast importation of silver into India will, concurrently with a sounder system of banking and finance, produce great effects upon prices in that country, and tend ultimately to produce great social changes.

Subjoined are tables of the imports (1) of gold, (2) of silver, for the six years 1858–63; (3) the exports of gold, (4) of silver, for the same period.

1. Gold imports.		2. Silver imports.	
	£		£
1858	22,793,126	1858	6,700,064
1859	22,297,698	1859	14,772,458
1860	12,584,684	1860	10,393,512
1861	12,163,937	1861	6,583,108
1862	19,903,704	1862	11,752,772
1863	19,142,665	1863	10,888,129

3. Gold exports.		4. Silver exports.	
	£		£
1858	12,567,040	1858	7,061,836
1859	18,081,139	1859	17,607,664
1860	15,641,578	1860	9,893,190
1861	11,238,372	1861	9,573,276
1862	16,011,963	1862	13,314,228
1863	15,303,279	1863	11,240,761

Precious Opal. A name for those varieties of Opal which exhibit a rich play of prismatic colours. It is found in irregular nests and veins, disseminated in trachyte, at Czerwenitza in Hungary, in Mexico, Ceylon, Iceland, &c.

Precipitate (Lat. præcipitatus, part. of præcipito, *I cast headlong*). A result of chemical decomposition, in which a substance is thrown

down in a solid, and generally in a finely divided state, from a liquid. The term *red precipitate* has been especially applied to the red oxide of mercury.

Precognition. In Scotch Law, the preliminary examination of witnesses respecting the commission of a criminal act, in order to ascertain whether there is ground for a trial, and to serve as directions to the prosecutor.

Predaceans (Lat. præda, *booty*). The English name used by Kirby as synonymous with the *Carnassiers* of Cuvier. [FERINES.]

Predazzite. A variety of Bitter Spar mixed with Brucite, which forms mountain masses at Predazzo in the Southern Tyrol. It has a granular structure, and is white with a vitreous lustre on the planes of cleavage.

Predestination (Lat. prædestinatio, the corresponding Greek term used by St. Paul being προορισμός). The belief that God has from all eternity decreed whatever comes to pass. In a theological sense, it is thus defined in the seventeenth Article of the English church: 'Predestination to life is the everlasting purpose of God, whereby, before the foundations of the world were laid, He hath constantly decreed by His counsel, secret to us, to deliver from curse and damnation those whom He hath chosen in Christ out of mankind, and to bring them by Christ to everlasting salvation.' The Lambeth Articles, agreed to in 1595 by a portion of the clergy, assert that 'God from eternity hath predestinated certain men unto life, certain He hath reprobated.' Theological writers have generally forborne to use the word *predestination* with respect to the rejected: 'Nefas est dicere Deum aliquid nisi bonum prædestinare.' (August. *De Dono Perseverantiæ.*) [ELECTION; CALVINISM.]

Predetermination. In Scholastic Philosophy, that concurrence of God which determines men in the performance of their actions, good or evil; called physical predetermination, or premotion.

Predial (Lat. prædium, *a farm*). Of or belonging to a farm. Thus we often read of *predial* slaves and slavery, in opposition to *domestic*.

Predicable (Lat. prædicabilis, *that may be said* of anything). In Logic, a term which can be affirmatively predicated of several others. The notions expressed by such terms are said to be formed by the faculty termed *abstraction*, after the particular circumstances characterising each individual have been withdrawn from it. The predicables are commonly said to be five: GENUS, SPECIES, DIFFERENCE, PROPERTY, and ACCIDENT (which is either separable or inseparable). [LOGIC.]

Predicaments. In Logic, certain general heads, or, in logical phraseology, *summa genera*, under one or other of which every term may be arranged. Aristotle enumerated ten predicaments; others, by subdividing some of these, have increased their number. Those of Aristotle are: substance, quantity, quality, relation, place, time, situation, possession, action, suffering. [ATTRIBUTE; CATEGORY; LOGIC.]

Predicate. In Logic, is, of the two terms of a proposition, that which is affirmed or denied of the other. [TERM; PROPOSITION; LOGIC.]

Predication. [LOGIC.]

Predisposing Cause. In Medicine, any circumstance which renders the body susceptible of disease.

Preface (Lat. præfatio, from præ, and fari, *to speak*). The observations prefixed to a work or treatise, intended to inform the reader of its plan and peculiarities.

Prefect. An important political functionary in modern France. Under the old régime, the officers who were sent round to the provinces to superintend the details of administration on behalf of the king were at first styled *maîtres des requêtes*. These were made permanent local officers in the reign of Henry II., and afterwards attained many additional powers, with the title of intendants. These were abolished at the Revolution, when various attempts were made to establish elective local governments. By a law of the year 1800 prefects were first appointed for the departments, with powers similar in many respects to those of the old intendants, with a council of the prefecture, and a general council of the department; which, however, fell into disuse. With slight variations, the prefects retain the same jurisdiction. They are, in some respects, analogous to our sheriffs; but with far greater powers. They possess not the nominal only, but the actual direction of the police establishment, within their respective departments, together with extensive powers of municipal regulation: the arrondissements or districts into which the departments are subdivided are under sous-préfets appointed by them. Their power, however, is controlled by that of the council of the prefecture, which acts in some measure as a court of appeal from the prefect, taking cognisance of various cases within the sphere of his administrative interference, if legal disputes arise upon it.

Prehnite. A hydrous silicate of alumina, of a greenish colour, originally discovered at the Cape of Good Hope, by Colonel Prehn. It is found in Cornwall, in Scotland, in the trap rocks of Edinburgh; and in the Isles of Mull and Skye. In Ireland it occurs in the granite of the Mourne Mountains.

Prelacy. [EPISCOPACY.]

Prelate (Lat. prælatus, *preferred*). A term commonly applied to bishops, archbishops, and patriarchs, in Christian churches. Anciently, mitred abbots seem also to have been called prelates.

Prelude (Lat. præludo, *I play before*). In Music, the preface or introduction to a movement, usually in the same key as the movement which it precedes; being, in fact, a preparation to the ear for what is to follow.

Premier (Fr.). The name generally given to the prime minister of England.

Premisses (Lat. præmissa). In Logic, the first two propositions of a syllogism. [SYLLOGISM.]

Premium (Lat. præmium, *profit*). In Finance, that market value of shares and stocks, in which the price paid for the ownership of the securities created exceeds the sum originally paid for them. When the market price and the sum paid are exactly equal, the stock is said to be at *par*; when the market value is less, the stock is at a *discount*. In the system under which loans were negotiated during the latter half of the eighteenth, and the beginning of the nineteenth centuries, the advantage gained by those who took the risk of subscribing the loan which was to be distributed subsequently among the general public, was called the *premium*, and the fact that in effect this premium or excess over the market price of public securities was always paid in the negotiation of any fresh loan, was quoted in order to show the inherent absurdity of the sinking fund of Dr. Price, by which loans were created for the purpose of liquidating debt by the agency of a compound interest. [FUND, SINKING.]

Premonstratensians (Fr. Prémontrés). A religious order of regular canons instituted in 1120 by St. Norbert (whence they are also called Norbertines), at Premonstratum, in Picardy, which is said to have derived its name from being *pointed out* by the Virgin. The canons of this order followed the rule of St. Austin, and were sometimes called White Canons, from the colour of their habits. They were brought into England about 1140, where they are said to have established thirty-five houses.

Prensiculantia (Lat. prenso, prehenso, freq. of prehendo, *I seize*). A name applied by Illiger to an order of Mammalia, corresponding with the *Glires* of Linnæus and the *Rodentia* of Cuvier, and indicative of the prehensile faculty with which the fore paw is endowed in most of the species of this order.

Preparation (Lat. præparatio). In Music, the previous adjustment of two notes by whose introduction a note which is to become a discord is heard in the preceding harmony. [MUSIC.]

Prepense (Lat. præ, and pendo, *I weigh*). In Law, an epithet, applied to MALICE, usually rendered in English by *aforethought*.

Preponderance (Lat. præpondero, *I outweigh*). In Artillery, the excess of weight of the portion of a gun in rear of the trunnions over the part in front. [GUN.]

Preposition (Lat. præpositio, from præpono, *I place before*). In Grammar, that part of speech which denotes the relations between objects; as *in*, *to*, *upon*. [GRAMMAR.]

Prerogative (Lat. prærogativa, applied in ancient Rome to that tribe, or century, which had the privilege of giving its votes—rogare suffragia—first at the comitia). A word in English Law, signifying the special rights of the sovereign, both as chief of the kingdom in point of honour, and as supreme magistrate intrusted with the execution of the laws. Prerogatives are said to be of two kinds, *direct* and *incidental*: the first, such as belong to the sovereign essentially by virtue of his high political character; such as the inviolability of his person, the appointment to offices and places of trust, the command of the army, the power of making war and peace, the supremacy of the national church, his legislative authority, &c.; and the latter, such exceptions as are made in his favour from the ordinary rules of law in private matters. Such are, with respect to debts, the power to levy first execution before other creditors, and of levying by the prerogative writ of extent; the power of taking goods and chattels in succession, which no other corporation can do; exemption from all customs, general and special, as to descent of lands, in a case where any such custom would have the effect of preventing lands held jure coronæ from passing to the successor; the abstract dominion of all lands and hereditaments by the fiction of universal occupancy; the right to derelict lands by the sudden retiring of the sea; the dominion of seas, navigable rivers, &c.

Prerogative Court. The court in which wills were formerly proved and administrations taken of the effects of intestates when the deceased had property in two or more dioceses of the same province, in which case the jurisdiction belonged to the archbishop of the province, by his prerogative. The jurisdiction in all such cases now belongs to her majesty's Court of Probate.

Presbyopia (Gr. πρέσβυς, *old*, and ὤψ, *the eye*). An imperfection of vision commonly attendant upon the more advanced periods of life, in which near objects are seen less distinctly than those at a distance. It is usually caused by a change in the consistence of the crystalline lens, effected as age advances; changes also by flattening of either the lens or the cornea may produce this state of vision. The change in consistence by induration of the lens interferes with the action of those muscles which compress it in health in order to adapt it to varying distances. Convex glasses must be used to remedy the defect. It often happens that one eye is more affected than the other, and in this case glasses of different foci should be used.

Presbyters (Gr. πρεσβύτερος, *elder*). An order of ministers in the Christian church, frequently mentioned in the New Testament as having the spiritual care of distinct congregations, and exercising a general superintendence over the concerns of the church. [EPISCOPACY; PRESBYTERY.]

Presbyterians. The name given to that body of Christians who have embraced the Presbyterian form of government. [PRESBYTERY.]

Presbytery (Gr. πρεσβυτέριον, *a council or assembly of elders*). That form of ecclesiastical polity according to which there is no gradation of order in the church, but which vests church government in a society of clerical and lay presbyters, or, in common phraseology, ministers and lay elders, all possessed officially of equal rank and power. The presbyterians

maintain that the words *presbyter* (πρεσβύτερος) and *bishop* (ἐπίσκοπος) are synonymous and interchangeable terms; that we nowhere read in the New Testament of bishops and presbyters, or of pastors of different rank, in the same church; and that deacons are laymen, whose sole duty it is to take charge of the poor.

The first presbyterian church, in modern times, was founded in Geneva by John Calvin, about 1541; and the system was thence introduced into Scotland, with some modifications, by John Knox, about 1560, but was not legally established there till 1592. For about a century from this date there was a continual struggle in Scotland between presbytery and episcopacy for superiority. The latter (which was patronised by the court) predominated in 1606; but was superseded by the former (to which the great body of the people were attached) in 1638. Presbytery kept its ground from this period till the revolution in 1660, when episcopacy again obtained the ascendency, which it maintained till 1688; soon after which it was abolished, and the national church of Scotland declared presbyterian--a form which it has since retained. The most numerous bodies of dissenters from the Scottish established church, such as the Associate and Relief Synods, are also Presbyterians; their cause of secession being that the church had relaxed the strictness of presbyterian principles.

Presbytery has never flourished much in England. An attempt was made to render the established church presbyterian in the reign of Charles I.; and this object was signally promoted by the famous Assembly of Divines at Westminster. In 1649, presbytery was sanctioned by the English parliament, but it was never generally adopted, or regularly organised except in London and in Lancashire. (Murray's *Life of Samuel Rutherford*, Edin. 1828, ch. viii.) Upwards of 2,000 presbyterian clergy were ejected from their cures in England, in consequence of the Act of Uniformity, in 1662. There are still many congregations (about 150) in England, particularly in the northern counties, called presbyterian. In Ireland, chiefly in the province of Ulster, there are about 500 presbyterian congregations. There are upwards of 100 such congregations in our North American possessions; and presbytery has also been introduced to a greater or less extent in the other British colonies.

In the United States of America presbytery embraces 5,660 congregations, with 4,785 ministers. (*Ency. Brit.* 8th edit. vol. xxi. p. 422.) The same system, though somewhat modified from that which obtains in Scotland, is established in Holland. (Steven's *Brief View of the Dutch Eccles. Establishment*, ed. 1839.) It still exists, though to a very limited extent, in Geneva; it prevails also less or more in several of the other Swiss cantons.

The constitution of the church of Scotland is as follows: The kirk session is the lowest court, and is composed of the parochial minister and of lay elders, the number of whom varies in different parishes, but is generally about twelve. The minister is moderator ex officio. This kirk session exercises the religious discipline of the parish; but an appeal may be made from its decisions to the presbytery, the court next in dignity. The presbytery, from which there is a power of appeal to the synod, is composed of the ministers of a number of contiguous parishes (varying in number in different cases), with a lay elder from each. A moderator, who must be a clergyman, is chosen every half-year. A presbytery generally meets once a month, but it must meet at least twice a year; and it may hold pro re natâ meetings. This court takes young men on trial as candidates for license; ordains presentees to vacant livings; has the power of sitting in judgment on the conduct of any of its members, and can depose them; and has the general superintendence of religion and education within its bounds. The synod, which meets twice yearly, is formed of the members, both lay and clerical, of two or more presbyteries. At every meeting a moderator is chosen, who must be a clergyman. The general assembly is the highest ecclesiastical court, its decisions being supreme. It meets annually in the month of May, and sits for ten successive days. Unlike the inferior courts, it consists of representatives chosen by the various presbyteries, royal burghs, and universities of Scotland. The number of representatives from presbyteries depends on the number of members of which each is composed. No presbytery sends less than two ministers and one lay elder; and none more than six ministers and three elders. The total number of members of the general assembly is 363, of whom about 200 are ministers. The assembly chooses a new moderator yearly, who, in recent times, is always a clergyman. The assembly is honoured with the presence of a representative of the sovereign, under the title of lord high commissioner; but this high functionary takes no part in the proceedings of the court, except in opening and closing or dissolving its sittings, and has no voice in its deliberations. The assembly before its close appoints a commission, which is equivalent to a committee of the whole house, being composed of all the members of assembly, and one minister additional, named by the moderator. The commission meets quarterly; but may hold pro re natâ meetings.

The income of the clergy, which may average about 250*l.* yearly, including manse and glebe, is regulated by the state; and they are nominated to livings by patronage. They have no liturgy, no altar, and with few exceptions no instrumental music. The Scottish presbyterians do not kneel, but stand in time of prayer; and in singing the praises of God they sit. The sacrament of the Lord's Supper is not administered in private houses to any person under any circumstances whatever. (*The Directory for the Public Worship of God, by the Westminster Assembly of Divines.*) Pluralities have been prohibited; and the

residence of clergymen within their respective parishes has always been imperative. Their creed is rigid Calvinism, and may be found embodied in the *Westminster Confession of Faith* and the *Larger* and *Shorter Catechisms*. But though the faith of the Scottish Presbyterians, whether churchmen or dissenters, is Calvinistic, not a few of the Presbyterians in other countries have adopted an Arminian, and not unfrequently a Unitarian creed. (Adams' *Religious World Displayed*, ii. 289–305; Lord King's *Inquiry into the Constitution of the Primitive Church*; Forbes' *Presbyterian Letters*.)

PRESBYTERY. In Architecture, the space between the altar and the easternmost stalls of the choir, answering to the *solea* of the ancient basilicas.

Prescription. A title acquired by use and time to incorporeal hereditaments, such as a right of way or of common, and the like. All prescription is either personal, as when it is in a man and his ancestors, or it is in right of a particular estate; which last being in a man, and those whose estate he hath, is called prescription in a *que* estate. It presupposes a lost grant, and can therefore give a title to those things only which can pass by grant. After uninterrupted enjoyment for forty, and in many cases for thirty or twenty years, a primâ facie title arises by prescription to the thing enjoyed; and unless such enjoyment have continued under some consent or agreement, the title becomes in sixty years absolute and indefeasible. The time of prescription in most of the ordinary instances to which it applies is now regulated by 2 & 3 Wm. IV. c. 71.

Presentation (Lat. præsento, *I present* or *show*). In Ecclesiastical Law, the act of offering a person to the bishop to be instituted to a vacant benefice.

Presentation, Feast of. In Ecclesiastical usage, a feast otherwise called the Purification of the Blessed Virgin. [PURIFICATION.]

Presentment. In Law, presentment is properly the notice taken by a grand jury of any offence from their own knowledge or observation without any bill of indictment laid before them at the suit of the crown, as the presentment of a nuisance or the like. The term is commonly used to include also inquisitions of office, and indictments by a grand jury. It is also used to express the formal notice taken in copyhold courts of the deaths of tenants, surrenders and admittances taken out of court, and other similar circumstances. Bills of exchange and promissory notes are said to be *presented* for acceptance or payment.

Preservation of Meat. Before giving an account of the different processes at present employed for the preservation of meat, it will be advisable to consider briefly the principles which determine the putrefaction of flesh under the decomposing influences of air, moisture, and warmth.

Muscular tissue, of which flesh is composed, consists mainly of the animal albuminous principle known to chemists as FIBRIN in a coagulated or semi-solid condition, permeated in all directions by a fluid composed partly of blood and partly of substances secreted from it. This fluid, which constitutes nearly three quarters, by weight, of all fresh meat, is composed of albumen in the soluble condition, the soluble salts of the blood, the crystallisable animal principles kreatine and kreatinine, lactic and butyric acids, the phosphates of potash, magnesia, and lime, and a small quantity of common salt —the whole being dissolved in a *watery fluid*. The albuminous principles fibrin and albumen are remarkable for the readiness with which they undergo decomposition, and break up into simpler substances, when under the influence of air, moisture, and warmth. The fluid constituents of flesh are, consequently, precisely in the most favourable condition for undergoing prompt decomposition, when submitted to the action of the atmosphere at a temperature even slightly elevated above freezing.

The process of putrefaction has been examined with great care and minuteness by several eminent chemists, but a detailed description of their researches would take up too much space; it will be sufficient for our purpose to know that albumen is a highly complex body, containing carbon, hydrogen, nitrogen, oxygen, sulphur, phosphorus, soda, and potash, and that when partly decomposed itself, it has the peculiar property, in common with its congeners fibrin and casein, of acting as a ferment, and inducing decomposition in the other animal substances with which it comes into contact. Decomposition being once fully set up, the solid and liquid portions of the flesh become gradually converted into gases containing fetid ammoniacal, sulphuretted, and phosphoretted compounds. These gases continue to be emitted until the whole of the meat is decomposed, nothing being left behind but the mineral constituents of the flesh and of its fluids.

Thus we see that four causes are concerned in the putrefaction of animal matter: air (or rather the oxygen which it contains), moisture, warmth, and decomposing albumen. Now, as no putrefaction can take place without a supply of oxygen, the whole of the processes at present in use are dependent on the more or less perfect protection of the meat from the action of the air. Thus, whether meat is preserved by being frozen, dried, salted, enclosed in air-tight cases, or covered with various substances, such as oil, varnish, or gutta percha, we may practically consider that their efficacy depends on one and the same cause—the exclusion of the air from contact with the meat.

Meat-preserving processes may be arbitrarily divided into the following classes:—

1. The application of cold.
2. Drying.
3. Salting.
4. Immersion in certain fluids.
5. Inclosure in air-tight vessels in vacuo or inert gases.

1. *The Application of Cold.*—The simplest of all preservative methods is that adopted in North

America, Russia, and other cold countries in the winter time, when frozen meat, fish, and vegetables form staple articles of consumption. During the coldest parts of the year, the markets of Montreal, Archangel, and St. Petersburg are filled with these frozen commodities, which when gradually thawed by being exposed to a gentle heat are found to possess all the qualities of fresh provisions, although they are generally many weeks old. The same means has been adopted for sending fish and other provisions to this country from distant parts, and the writer has tasted game shot in the prairies of Western America and sent to London packed in ice, whose only fault consisted in its being rather too fresh. The same method has also been employed to insure the successful exportation of salmon and trout ova to Australia [PISCICULTURE]; and the use of ice as a preservative of meat, or at any rate as retarding its putrefaction, is constantly resorted to during hot weather in this country. In the case of frozen provisions, the air being, of course, excluded from them by the ice in which, so to speak, they are immersed, no putrefactive action can take place. When a diminished temperature only is employed, the decomposition is simply retarded, but not altogether prevented.

2. *Drying*.—The next simplest process is that of drying the meat thoroughly, either by natural or artificial means. In all hot countries, more especially in South America, the natives are in the habit of cutting their meat into thin strips, and exposing these to the sun until they are thoroughly hard and dry. The American Indians pound their meat in rude mortars until it forms a paste, which is mixed with fat. This paste is afterwards made into bricks, dried and sold to the hunters under the name of *pemmican*. From its mode of preparation, pemmican contains a large amount of nutritive matter in a comparatively digestible state, and is sufficiently palatable to those who have nothing else to eat. Pemmican is prepared in large quantities at Gosport for the use of the navy. The beef, trimmed and deprived of fat as much as possible, is cut in thin slices, which are placed in hot plates until they become perfectly dry. They are then reduced to a coarse fibrous powder, and mixed with a certain amount of fat. To some kinds sugar and currants are added. It makes excellent broth, containing a large amount of nutritive matter, and is preferred by many sailors to canistered preserved meat. South American beef, or charqui (*chair cuite*, Fr.), is made by cutting the meat into slices, salting, and drying by artificial heat. Large quantities were sent to this country in 1863–4, and sold retail at 4*d*. per pound; but owing to many samples being half-tainted when they arrived here, the retail buyers became disgusted, and the sale has greatly diminished. The salting, of course, deprived it of a large portion of its nutritive principles, and the drying rendered it so hard as to be cooked and digested with great difficulty. All drying processes depend for their value on the coagulation and consequent hardening of the albumen contained in the meat, by which it becomes impervious to the action of the air. The same object is gained by the process of *smoking*, or exposing the meat, first partially salted, to the fumes of burning wood or peat. Peat or wood smoke contains a certain quantity of KREASOTE, a bitter principle which coagulates the albumen on the outer parts of the meat. Meat and fish may be preserved a short time by simple smoking; but the so-called smoked beef, ham, and fish, is in reality salt beef, ham, and fish smoked on the outside to obviate the necessity of packing it in salt.

3. *Salting*.—We come now to the various salting processes, the first of which is the ordinary method of salting beef and pork. The following is the process adopted, with slight modifications, for the beef and pork used by the navy. Twenty-four hours after the animals are slaughtered, the beef is cut up into 8lb. pieces, the pork into pieces of half that weight; they are then rubbed with salt, and placed in tanks filled with dry salt, where they remain from eight to twenty days, according to circumstances, after which they are stored in casks of dry salt. This prolonged application of salt has the effect of dissolving out nearly the whole of the nutritious juices of the meat, ultimately leaving little behind but hardened fibrin.

Several means have been tried to obviate this destruction of the valuable matter contained in the meat; the latest of these being that devised by Professor Morgan of Dublin. It is, we believe, a modification of a method originally invented by M. Gannal. The animal is killed in the usual way by a blow in the head, care being taken not to rupture any of the large bloodvessels. The chest is then cut open, and the heart laid bare by an incision in the pericardium. The right and left ventricles are next opened, and the blood allowed to run out by laying the animal on its side. A pipe furnished with a stopcock and coupling at the outer end is now introduced into the aorta through the left ventricle, a piece of stout cord being passed round the pipe and the aorta to hold them together. The coupling is then connected with eighteen or twenty feet of Indian rubber piping, which communicates with a tank or trough containing the salting liquor elevated to the height of the length of the Indian rubber tubes. The tap being turned, the salting liquor at once enters the aorta, and running through the whole of the animal's vascular system flows out at the right ventricle. This salting liquor is ordinary brine in which a small quantity of saltpetre has been dissolved, and may be used several times, its use being to clear out the vessels and prepare them for the second salting liquor, which is composed of one gallon of brine, half a pound of saltpetre, two pounds of sugar, half an ounce of monophosphoric acid, and a small quantity of spice to every hundredweight of meat.

The saltpetre (nitrate of potash) and phosphoric acid are added to supply the potash salts and phosphates which are washed out by the liquor. The connection with the aorta being made as before, the right ventricle is this time tied up securely, and the tap being turned on, the liquor in a very few minutes percolates through every vessel in the body, even those contained in the skin, hoofs, and horns. In the course of a few days the animal is skinned and cut up into the usual 8 lb. pieces, which are either casked with salt or dried in a hot-air chamber.

Professor Morgan has established several factories in different parts of South America for the preparation of beef by this method. The Admiralty also have had his plan under trial for several months, and the officers who have tested it report favourably upon it.

Other preservative agents, such as the acetates of soda and ammonia, the chloride of aluminum, and several others, have at various times been experimented on; but common salt with a certain admixture of saltpetre and sugar appears to form the best material for salting.

Solution of salt appears to act in preserving meat by filling up its pores with a liquor that will not absorb oxygen, but of all processes it is the most pernicious and unphilosophical. As we have before remarked, the largest amount of nutritive matter resides in the fluids contained in the flesh. To say nothing of the albumen, these fluids are charged with salts of potash and lime, and several phosphates, all of which are absolutely necessary for the formation of blood, muscle, and bone, in the living being. The two animal principles, kreatine and kreatinine, are also found in the liquid permeating muscular fibre, and are considered by several chemists to be analogous in their action on the human subject to theine, so that beef *tea* is not such a misnomer as one might suppose. By the process of salting, all these important substances are gradually washed out into the brine, and in course of time nothing remains but hardened fibrin, which, by itself, can afford little nourishment to the human body. From this it will be readily seen that the use of salt meat in any form is unwholesome unless care be taken to supply some of the constituents that remain in the brine and water in which it has been soaked. By Professor Morgan's method a large amount of valuable nutritive material must be lost in the process of washing out the capillaries and other smaller vessels; and when the meat is cut up and casked, the objections made to ordinary salt meat still hold good, although in a more limited degree. Various plans have been devised from time to time to recover the nutritious matters dissolved in brine, but hitherto without success. The process of removing the salt by dialysis appears to offer the best hope of effecting this object.

4. *Immersion in Fluids.*—This class of preservatives may be soon dismissed. Treacle, strong syrup, glycerine, weak vinegar, solution of sulphurous acid, and several other liquids, have all been tried; but from one cause or other they all seem to have failed practically. Sardines, pilchards, and other small fish are preserved in oil in enormous quantities with the greatest success; but from the expensive character of the material, the principle, though sound, is inapplicable to provisions in large pieces. It need hardly be stated that alcohol, benzol, turpentine, solution of arsenic, corrosive sublimate, &c., although perfectly applicable in the case of anatomical preparations, are utterly useless for substances intended for food.

5. *Preservation in Vacuo and Inert Gases.*—These methods are intended for the preservation of meat in its unsalted state. It is hardly possible to over-estimate the importance of a perfect process for preserving meat in a fresh condition. The history of fresh preserved meat is closely connected with Arctic discovery. The exertions made by navigators to discover the North-West passage first created a demand for this form of food, it being found that the evils arising from living exclusively on salted provisions were fearfully aggravated by the rigours of a cold climate. The Admiralty were therefore incessant in their efforts to induce manufacturers to devise some process for doing away with salt meat; and towards the beginning of the present century numerous experiments were made by various persons, with, however, but little success. As soon as the modification of Appert's process by Donkin, Hall, and Gamble was made practically perfect, it was at once tested by the Admiralty, who sent out large quantities of the preserved fresh meats to the Arctic regions by ships starting on voyages of discovery. The provisions were reported on favourably by the officers in charge of the expeditions; and, their value in cold climates being once known, their use was soon extended to the East and to the West Indies and other tropical regions. For ship use, they were found invaluable, and at the present time hardly a vessel leaves this country without a supply of fresh preserved provisions. In India they are extensively used as luxuries in the towns, and as necessities in the remote districts where fresh meat of any kind is scarce and bad.

The first successful attempt made to preserve meat fresh was by M. Appert, a French gentleman, who in 1810 received a prize of 12,000 francs offered by the Board of Arts and Manufactures in Paris. In the following year, M. Durant, a colleague of M. Appert, took out a patent for the process in this country. The patent was subsequently declared to be invalid, the Society of Arts and Manufactures of London having previously presented a premium to a Mr. Luddington for a method of preserving fruit without sugar, the principle of which was said to be the same as that adopted by Appert. The patent was nevertheless purchased by Messrs. Donkin, Hall, and Gamble for 1,000*l*. They at once effected a great

improvement by abolishing the use of glass vessels, and substituting tin canisters in their stead. Although the use of air-tight vessels was an essential part of Appert's process, it seems to depend for its value more upon the cooking, or rather over-cooking, of the meat, by which the albumen was rendered insoluble, than upon the perfect exclusion of oxygen, that gas having been found in appreciable quantities in tins containing meat in a perfectly sound condition.

Appert's process consisted in partly cooking the meat, placing it in a glass vessel in a bath of chloride of calcium, heating it to about 240° for a length of time depending on the size of the piece of meat, and then hermetically sealing the lid. After this, it was again heated for a shorter or longer time, and the process was considered finished.

Donkin and Gamble's process, which is now adopted in all parts of the world, is as follows, The meat, which has been previously parboiled, is placed in tin cylinders containing a rich soup or gravy; the lids, which are pierced with a small hole, being soldered down air-tight. They are then immersed in a bath of brine or chloride of calcium, and heated to boiling-point, until the meat contained in them is supposed to be completely cooked. While the steam produced by the boiling soup is issuing from the orifice in the cover, the jet of vapour is suddenly checked by the application of a wet rag, a drop of molten solder being dexterously applied to the hole at the same moment, and so the case is hermetically sealed. The sealed tins are once more, in order to insure the perfect coagulation of the albumen, submitted to the hot bath, for a time proportionate to their size and the nature of their contents. On cooling, the ends of the canisters, which are purposely made of thin tin-plate, become slightly convex from the outward pressure of the atmosphere. They are afterwards exposed to a temperature of 100° Fahr. in a hot-air chamber for several weeks, at the end of which time they are examined. If any of the ends are found to have flattened or bulged outwards, either the case has not been soldered air-tight, or the contents have putrefied and liberated the gases, causing the ends to become convex from inward pressure.

The process has been greatly improved by Messrs. McCall and Co. of Houndsditch, who introduce into the tins a small quantity of sulphite of soda to effect the absorption of any traces of free oxygen which under the most favourable circumstances may lurk in the cases. This salt, which both in the solid and liquid state has a great affinity for oxygen, is used in the proportion of twelve grains to every pound of meat. The sulphite of soda is at first contained in a small air-tight tin capsule, which is soldered to the interior of the lid of the case, the salt being retained in its place by a plug of soft solder which melts at 218° Fahr., i.e. 6° above boiling-point. The meat being prepared as in Donkin and Gamble's process, it is placed in the tin, the lid being soldered down and heated in the salt bath until steam issues at the hole in the lid. A drop of solder is applied as before, and the steam inside the air-tight case becoming superheated, the soft solder on the capsule melts and releases the sulphate of soda. The effect of this improvement is to lessen the necessity for prolonged steaming and over-cooking, which is one of the great objections to the ordinary method of meat preservation. In the case of soups, the salt is generally mixed with them before they are enclosed in the canisters.

An improvement upon all these processes has lately been patented by Messrs. Jones and Trevethick, of Botolph Lane. It is conducted in the following manner:—

The raw meat, without any further preparation, is wrapped up in a clean piece of cloth and placed in a tin, the lid of which is soldered down. From the top of the case projects a small tube, which is placed in communication with an air pump, a very ingenious contrivance being adopted to prevent the cases collapsing from the outer pressure of the air. This is accomplished simply by placing them in water in an air-tight vessel. When all the air is exhausted, pure nitrogen gas, which is absolutely without action on animal matter, is let into the case. This has the effect of diluting almost infinitely any traces of oxygen that may remain in the meat or tin. The nitrogen is in its turn exhausted, and a minute portion of sulphurous acid gas is allowed to enter the cylinder, having the effect of perfectly absorbing any remaining traces of oxygen. Another charge of nitrogen is then admitted, and the case is finally soldered, the nitrogen, by filling the case, of course preventing any collapse from atmospheric pressure.

The great merit of this process consists in the fact that the meat is preserved in its natural and uncooked state. At the jury dinner which took place at the International Exhibition of 1862, mutton, beef, and poultry, many months old, were produced, which, for anything that could be guessed from their perfect freshness of flesh and flavour, might have been killed the day previously. When the cases were opened, the poultry and game had the appearance of having been but an hour from the poulterer's; and although the butcher's meat appeared on close inspection to be slightly redder than usual, nothing could be detected, either by touch, taste, or smell, that would preclude an ordinary observer from declaring it to be perfectly fresh. This method is one of the most valuable yet invented, and if it can be practically worked will be of inestimable benefit to all classes of the community.

Patents have also been taken out for preserving meat by enclosing it in air-tight cases along with vessels containing sulphide of calcium and other salts capable of absorbing the oxygen from the air in the case; but none of these have been yet applied to actual practice.

The principle of preserving meat by perfectly excluding the air is also applied largely

in the case of sausages and potted meats. Various experiments have been tried, and numberless patents have been taken out, for methods of covering provisions with various varnishes, gutta percha, Indian rubber, wax, paraffin, plaster of Paris, &c. &c.; but as none of them are practicable, it would be useless to describe them.

President (Lat. præsideo, *I sit foremost*). A title applied to many officers in various capacities, but generally denoting a pre-eminency, either temporary or fixed, among a number of persons assembled for a definite purpose. Thus the superior of a board or council, &c. is generally entitled president, as is anyone who is called to preside over an occasional meeting, or to fill the chair at a club, dinner, &c.; although the old English title of chairman is frequently used on such occasions.

The supreme executive officer of the United States of America is styled *president*. The qualifications required of a person raised to this dignity are, to be a natural-born citizen of the age of thirty-five years, and to have resided fourteen years within the states. The election is by electoral colleges in every state. These colleges contain, in each state, a number of electors equal to all the senators and representatives of that state in congress; but their appointment varies in different states, and at different times; sometimes it is made by their respective legislatures, sometimes by general election throughout the state, sometimes part of the electors are chosen by district and part by general election. The colleges in each state vote by ballot for a president (and at the same time for a vice-president); and the votes of all the electors, taken in this manner, are counted by the president of the senate: if in this numeration any person is found to have an absolute majority of votes, he is duly elected; if not, the election is made by the house of representatives between the three persons having the highest number; in which case the votes are taken by states, and a majority of all the states is necessary to constitute a choice. On two occasions, of which the last was in 1824, no candidate having had a majority of the whole number of voters, the house of representatives has proceeded to make the election; and, on the last of these occasions, a majority of states chose a candidate (Adams) who had a smaller number of electoral votes than one of his opponents (Jackson). On one occasion, in 1800, the states balloted thirty-six times before any candidate could obtain an absolute majority. Should the president die during his term of office, he is succeeded by the vice-president. In this manner the present president, Andrew Johnson, succeeded to the office on the assassination of Abraham Lincoln.

In his legislative capacity, the president has the power of approving bills sent to him after passing both houses of congress, or of returning them to the house in which they have originated with his objections annexed. In the latter case, the bill must be reconsidered by that house; and if, on reconsideration, it obtain a majority of two-thirds in both houses, it passes into a law. In his executive capacity, he is commander-in-chief of the army and navy of the Union, and of the state militias when called into the service of the Union; he has the power of reprieving and pardoning except in cases of impeachment; he has power to make treaties, with the consent of the senate (by a majority of two-thirds); he nominates ambassadors, consuls, judges of the supreme court, and all other officers of the United States whose appointments are not vested elsewhere by the constitution.

The supreme magistrate of the French Republic, 1848, was also styled *president*, elected for four years by universal suffrage.

President, Lord, of the Council. The fourth great officer of state in England; appointed by letters patent under the great seal, durante bene placito.

Press (Fr. presse). The machine (whether worked by hand or by steam) by which books, &c. are printed. Very little improvement in the construction of this instrument took place from the first introduction of the art of printing into Europe till the late Earl Stanhope introduced his press. The old press was made of wood, with an iron screw that had a bar fitted in it; to the lower end of this screw was attached, horizontally, a flat piece of wood, called the *platen*, which, being brought down by means of the screw, pressed the paper upon the face of the types; and thus the impression was obtained. This press has, however, entirely given place to presses made of iron. Lord Stanhope's press is constructed of iron, with a screw; but the bar is fixed to an upright spindle to which a lever is attached connected with a second lever fixed to the top of the screw by a connecting bar. These two levers are placed at different angles to each other; and when the platen is brought down to the face of the types, and power is wanted, the two levers take such a position with each other as to act with the greatest advantage, and thus an almost incredible accession of power is gained, which enables the pressman to print larger sheets of paper in a superior manner, and with greater ease to himself. This press maintains its superiority in some respects over all others.

The great improvement thus effected in the printing press excited other ingenious men to exert their abilities in attempts at further improvements; among whom was a Mr. George Clymer, an American, who brought forward an iron press, called the Columbian, in which he discarded the screw, and obtained his power entirely by levers. This press has great power, and consequently great capacity, but for the common run of printing it does not work so easily as the Stanhope. These two are looked upon as the best presses.

There are many other presses which are great improvements upon the old construction, and which are held in estimation by printers, but the limits of this work will not admit of the details of their respective merits.

The *book press*, in the warehouse department, used for pressing books previous to their delivery, is the common screw press, with a perpendicular screw, and screwed down by means of an iron bar; it is also used for pressing paper, when wetted, previous to being printed on, for the purpose of making it in better condition for the process; and also in cylindrical or machine printing, to cause it to lie flat, as it is apt otherwise to wrinkle, particularly when in large sheets, in being carried round the cylinders. In large establishments Brahmah's hydraulic press is generally used for these purposes, as being much more powerful, and also more expeditious, not only in its use, but also in its effect.

PRESS. A machine for the purpose of compressing or squeezing bodies. Any of the mechanical powers may be used for this purpose. When constructed on a large scale, the hydrostatic pressure of water is the power generally employed. [HYDROSTATICS.]

PRESS. A term metaphorically applied either to the whole literature of a country, or to that part of it which is more immediately connected with newspapers or other periodical publications.

Press Proof. In Printing, a good impression of a sheet by which it is read over carefully before being printed off.

Pressirosters (Lat. pressus, *flattened*; rostrum, *a beak*). A tribe of wading birds, including those which have a flattened or compressed beak.

Pressure (Lat. pressura). Dr. Young defines pressure to be 'a force counteracted by another force, so that no motion is produced.' (*Lectures on Nat. Phil.*) Thus, when a heavy body is supported on a table, or the ground, the force of terrestrial gravity, which, if the support were removed, would cause the body to descend towards the centre of the earth, being destroyed at every instant by the resistance of the support, produces a pressure. A pressure and a moving force differ from one another only in this respect, that the infinitely small velocities which the pressure tends to produce are incessantly destroyed by the resistance of the obstacle; whereas those that are actually produced at every instant by the moving forces are accumulated in the moving body, and produce a finite velocity after a finite time. The pressures of two different bodies are, therefore, to each other as the masses multiplied by the infinitely small velocities which they tend to produce in the same instant of time, and which they would produce if the bodies were free to move.

Pressure, Centre of. [HYDROSTATICS.]

Presswork. In Printing, the operation of taking impressions from types, &c. by means of the press; distinct from *composing*, which is arranging the types to prepare them for press. By *fine presswork* is meant work printed with the best paper and ink, and with the utmost care at a hand press.

Presto (Ital.). In Music. [TIME.]

Presumption of Law. The assuming the truth of a certain state of facts by the ordinary custom of the law. It is either *juris et de jure*, which is a presumption which no evidence to the contrary can be admitted to traverse, as the presumption of incapacity in a minor with guardians to act without their consent; or it is *juris* only, which may be traversed by evidence, as where the property of goods is presumed to be in the possessor until the contrary is shown.

Presumptive Heir. [HEIR.]

Pretender. The name by which the Chevalier Charles Stuart and his father are usually known, from their having pretended a right to the British crown, from which they had been excluded.

Prevarication (Lat. prævaricatio, *a going in a crooked direction*). In Roman criminal law, several special kinds of fraud have been so entitled; in particular, that of an agent or advocate, who by collusion with the opposite party damages his employer. The popular English sense of the word is altogether different.

Preventer. On Shipboard, a term applied to any rope, chain, bolt, &c., which is placed either temporarily or permanently as a deputy or duplicate for another similar instrument. Its object is to relieve the other rope, &c., or to take its place in the event of carrying away.

Prevention (Lat. prævenio, *I come before*). In Civil Law, prevention takes place where one of two parties equally authorised to commence legal proceedings does so, and thereby forestalls the other.

Preventive Service. [COAST GUARD.]

Previous Question, The. In English parliamentary usage (whence it has been borrowed in the practice of other legislative bodies) the *previous question* is termed by Mr. May (*Parliamentary Practice*) 'an ingenious mode of avoiding a vote on any question which is proposed.' When a question is about to be put by the Speaker (in the House of Commons—the usage of its committees is different), a member may interpose by moving that the same question 'be *now* put,' and if this be negatived, then the main question cannot be put at that time. [PARLIAMENT.]

Prévôtales, Cours (Fr. *courts of prévôts* or *provosts*). Certain tribunals of summary jurisdiction, which existed in France before the Revolution, and were for a short time reestablished in 1815.

Priam. In Mythology. [PARIS.]

Priapus (Gr.). In Mythology, a son of Dionysus (Bacchus) and Aphroditê (Venus); but there are several accounts of his parentage. He was looked on as the cause of fertility to fruits and flocks. From the worship specially paid to him at Lampsacus, he is often spoken of as Hellespontiacus. (Hor. *Sat.* i. 8; Ov. *Fast.* i. 415.) [LINGA; MYSTERIES; PHALLUS; YONI.]

Price (Ger. preis, Fr. prix, from Lat. pretium). In Political Economy, the estimate

in money of the value of any article in demand. It has been distinguished as twofold: the natural price, i. e. the ratio which the money value of commodities has to the cost of production; and the market price, i. e. the rate at which, consequent on supply and demand, a commodity is exchanged for money, at any particular time. The market price continually oscillates about the natural price; it is occasionally below it, and under certain circumstances may far exceed it. The two will coincide only when the demand rises and falls exactly with the supply, a state of prices which cannot, of course, ever be permanently secured. Furthermore, price is to be distinguished from value. Value is either relative to the cost of production, or to the demand which is made for the commodity, but values exchange exactly against values. In price, however, two elements have to be considered: not only the value of the article sold, but the cost of producing the general measure, money, has to be taken into account. Hence there may be a rise or fall in prices, consequent not upon the cost of production or the demand of purchasers, but upon the relative value of the precious metals. Thus the value of wheat in relation to the value of wool or any other commodity will remain the same; for if a quarter of wheat costs as much to produce as forty pounds of wool do, the value of the measure and the weight will be identical. There cannot, therefore, be a general rise in values. But prices have risen and fallen according to the dearness or cheapness of the precious metals. For instance, a quarter of wheat was worth, say, 6*s.* 8*d.* five hundred years ago, and is worth 50*s.* now, i. e. there is a rise in price amounting to seven and a half times, partly consequent upon the diminution of the weight of silver in the same denomination of currency, partly because silver is procured at a cheaper rate, i. e. at less labour, at present than at that time.

The history of the great change of prices which took place in the sixteenth century, has not yet been written. It was due partly to a radical change in the currency, partly to the distribution of the precious metals over the Old World consequent upon their discovery in the New. Had these metals been produced and distributed according to the general process by which mines are worked at present, though there can be no doubt that a rise in prices must have eventually taken place owing to the comparative ease with which silver was found, yet the facts would have been different, both in character and degree. After the occupation of Peru by the Spaniards, the mines whence the largest quantity of the new silver was procured were worked by the compulsory labour of the natives; and the silver having been procured at little cost to those who reaped the fruit of this labour, was exchanged cheaply against imported commodities. If, however, the mines had been worked by voluntary labour, the addition would have been more gradual, and the cost of production being fully equal to that of any other commodity, the effects would have shown themselves more slowly. It is, we believe, due to the fact that the discoveries of gold and silver in California, Australia, and New Zealand have been turned to account by the labour of voluntary colonists, that, prodigious as has been the amount added to the stock of bullion possessed by the civilised world, the rise in prices which is suspected to have ensued from this addition is still a matter of doubt, and if decided affirmatively may be even then assigned to other and co-ordinate causes.

The price of a commodity is not based upon its rarity, or on its utility, but on the demand for it, i. e. on the difficulty of satisfying the desire of possessing it. Some of the metals which have been recently discovered are of excessive rarity, being disseminated in the ore from which they are taken in very minute quantities, as for instance by two or three grains to the ton. But, except to those who are curious, they have no value, and no price, and will have none unless some use in the arts, which shall create a demand commensurate with the cost of producing them, should hereafter arise, and thus create a need of them. This was the case with the metal platinum. When it was first discovered, it was exhibited in the form of dust, or of a very slightly coherent powder. As in the existing state of chemical science, it was wholly infusible, it could not be made to possess the ordinary qualities of the useful metals, malleability and ductility. When, however, Dr. Wollaston discovered a means of welding it, and its remarkable properties in this shape became known, it became an article of great commercial value, having been employed to form stills for the concentration of sulphuric acid, a commodity in its concentrated form of such mercantile importance, that its consumption is said to be the measure of the economical progress of a nation. Again, the utility of some objects is of immediate and permanent significance. Human life can be continued but for a few minutes in the absence of air, or when its supply is scanty, or when its quality is depraved. But air, since there is no difficulty in procuring it, has no value and no price. In deep mines, or in diving bells, it has a price, because labour is necessary to supply it; in other words, because it is difficult of attainment.

In consequence of the fact, that difficulty of production, and demand, concur in elevating the price of commodities, certain general rules may be laid down which may be said to denote the laws which govern the rise and fall in the price of commodities, the value of money being supposed to remain unchanged.

1. In commodities of urgent demand, but of such a quantity as cannot be susceptible of immediate increase, the price of a deficient supply will rise far above the ordinary rate, the aggregate quantity available for consumption selling for a far larger sum than the ordinary amount could be sold for. This is the case, for instance, with the amount of food in a city which is closely

besieged, and in that possessed by a nation which imports no supplies from abroad, whenever a dearth or famine arises. In this country, during the existence of the corn laws, the nation put itself voluntarily into a state of siege, and suffered the evils of famine when it had all the means of plenty. At the present time, as trade in corn is free, communication rapid, and the harvest goes on over the world all the year round, the contingency of a dearth in the necessaries of life, as far as bread is concerned, is as remote as the risk of a general deficiency of harvests over the whole world could be.

2. In commodities the demand for which is constant, but the supply is absolutely fixed, the price of the commodity will rise with the demand, and will stop only with the contingency of the rate of profit or satisfaction not being realised on the purchase. This is the case with land available for building or cultivation. There is no known limit which can be put to the rent or purchase (the two terms differing only as annual and permanent possession) of land which is demanded for buildings in advantageous sites for commerce, as long as a rate of profit may be procured on the land thus rented or purchased. A rise in the rent, or in the value of the fee simple of land, is derived wholly from increased production; and the productiveness of the soil, whether in trade or agriculture, is as yet, and long will be, an indeterminate quantity, for in all likelihood the rate of production from the soil of this country, even in the existing state of agricultural science, is only half what it might be were it possible to apply larger capital to the soil by the liberation of land from some of the real burdens which affect it, the hindrances, namely, to its distribution.

3. In commodities the demand for which is steady, and the supply capable of extension at increased cost to the producer, the price will rise steadily according to the demand and the increased cost. Thus clothing can be manufactured from several materials. A deficiency in the supply of one of these will be met by an increased rise of another. Thus, were cotton the only material available for clothing, the deficiency of the American market would have raised the price of clothing at a rate analogous but not equal to a rise in the price of food consequent upon a general scarcity. It would not be an equal rise in price, for a greater economy may be maintained in the use of clothes than in that of food. The full rise was, however, met to some extent by the use of other raw materials, as wool, silk, flax, alpaca, and the like. So it has constantly been found that a deficiency in the supply of a great convenience of life from one source is met by the discovery of the same or a similar utility in some new quarter. The hindrances put on the use of cane sugar during the great French war, led to the cultivation of beet for the supply of this commodity. A similar cause suggested the discovery of certain sources of saltpetre. A deficiency in the supply of hemp has led to the extensive use of jute. Deficiencies in the raw material of paper have led to the use, as yet partial, of other tissues than cotton and flax. It has been stated, though on somewhat doubtful authority, that the blockade of the Southern ports of the American Union during the late civil war has been the means by which economical discoveries of great importance have been made in some of the states which composed the extinct Southern confederacy.

4. In commodities which can be produced in indefinite quantities at no increased cost, or at only such an increase as is due to the demand for labour, the price, even if demand increases greatly, will be affected only to a slight extent. Thus iron and coal can as yet, it appears, be supplied from this country in indefinite quantities, the amount produced being determined solely by demand. In this case, if labour be abundant and the competition for land from which these articles can be obtained is not so great as to create a general rise in rents for mining localities, prices will remain stationary. Even when a rise in rents is effected, and labour is comparatively dear, improvements in the process of production may serve to neutralise the consequences which might otherwise have fallen on consumers. Thus the consumption of coal and iron for the home and foreign trade has increased to an enormous extent during the last two years, but without a corresponding rise in price. Here, again, the theory which concludes that a great fall has of late years taken place in the price of the precious metals, or, in other words, that a general rise in prices has occurred, may be refuted, if it be shown, first, that these metals have been produced at equal cost to the miner, or, which is far more important, have been procured at equal cost by the exporter of them.

5. In commodities whose use is wholly voluntary, a great deficiency of supply may occur without any great increase of price. Thus the price of wine in countries where the use of this stimulant is confined to a small section of the community, and only the better growths are consumed, may not rise very markedly even when the vintage has failed to a very great extent. Spanish white wines, we are told, have risen largely in price during the last two or three years. This, however, is not due to deficiency of crops, but to a very great increase in the demand, consequent on a greater inclination and a wider power of purchase among the community. In short, where the article is one of voluntary use, a slight increase in price, or even a threatened increase of price, may stop demand, and arrest the enhancement of the market value.

Price of Money. This expression is exceedingly ambiguous. It means occasionally the rate at which the precious metals are procured in exchange for other commodities. In this sense the laws which govern the price of gold and silver are in no way different from

those which regulate the cost of other commodities. It is by means of these laws that the precious metals are distributed over the world, the demand, namely, for their use in commerce and the arts, and the power of exchange which the possessor of every object in demand holds in the several markets of the world. It may also, and often does mean, the ease or difficulty with which capital may be lent or borrowed; in other words, the fulness with which credit is given or taken, and from this point of view it is influenced by the state of the foreign exchanges, i.e. by the need which there may be of exporting money or increased quantities of goods at lower prices in order to equalise transactions, and by the rate of discount in the advances made by bankers and bill brokers. The origin of this use of the phrase, *the price of money*, to express what is in effect the price of credit, is to be found in the universal, and indeed necessary practice of estimating all values by money prices. The money is a mere instrument, often being but the basis of a series of transactions representing in their aggregate amount much more than the gold and silver in which they are estimated. For the phenomena which characterise these facts, see DISCOUNT and EXCHANGE.

Price at the Mint, or Mint Price.—The value of gold at the Mint is 3*l.* 17*s.* 10½*d.* the ounce, British standard, and any person may bring gold of standard value to the Mint in quantities of not less than 10,000*l.* in value, and receive in exchange, after the time necessarily spent in manufacturing the same into currency, the same amount, weight for weight, in gold coins, the rate of coinage being 1,869 sovereigns to 40 lbs. troy weight of gold, the gold being $\frac{11}{12}$ fine. The expression, therefore, *Mint price of gold*, only denotes the value of the currency contained in the troy ounce.

The general theory of prices, and the largest information as to prices of commodities, and the causes which have induced, during the history of the last sixty or seventy years, fluctuations in prices, are to be found in the work of the late Mr. Tooke, continued by Mr. Newmarch. Of all the questions discussed in these volumes, those of the prices of corn and the price of mercantile accommodation are the most important. Much, indeed, of the reasoning on both these heads has been controversial. Dissertations on the causes which induce fluctuations in the price of food have, it is true, been rendered comparatively unimportant by the changes which have happily occurred in consequence of the reform of the tariff and the repeal of the corn laws; but the question whether the price of money, in the technical sense of the rate of discount, has not been made liable to excessive fluctuation, is still an open one. On one point all persons are agreed, that there is nothing which is more desirable for producer, dealer, and consumer, than a generally uniform price, and that anything which reduces the oscillations of the market price to the lowest possible amount in relation to the natural price, is of the highest importance and benefit.

Prices of Foreign Produce. The price of an article procured from a foreign country depends not upon the cost at which it is produced, but on the cost at which it is procured. For instance, the cost of a cask of Spanish wine is determined not by the price of labour, the rate of profit, and the rent of land in Spain, but by the elements which make up the cost of the commodity or commodities against which the wine is exchanged in the country to which it is exported. Were all transactions between countries carried on in money, the rule would still hold good, though to a less extent; for money is produced and imported just as any other commodity is, by exchange for other commodities, and the specie may be procured by one country at cheaper rates than it can be by others. In case, however, that both countries produced gold and silver, and produced them at the same cost, the price of a commodity like that of wine would be equal in the two countries, with the addition in the case of the importing country of the cost of carriage. Such a combination of circumstances can, however, occur but rarely, if indeed it be not wholly hypothetical. Hence it may happen, that, value for value, a commodity can be procured at cheaper rates in an importing country, than it is in the country which produces it, and if the cost of carriage were omitted, continually would be. Hence, also, the price of the precious metals may be lower in countries which do not produce them, than in countries which do.

Prick Post. In Architecture, a post in wooden buildings framed intermediately between two principal ones. The term is generally used to express the intermediate post between two guide ones that are driven into the ground in the case of a wooden fencing.

Pricking Up. In Architecture, the first coating of lime and hair in work of three coats upon lath. It is executed in London with coarse stuff made with road drift or Thames sand; and the surface is scratched over with the trowel to enable the succeeding coats to obtain a better hold of the pricking-up coat.

Prickles. In Botany, the hard, sharp-pointed conical processes found on the epidermis of plants.

Prickly Ash. The name of the *Xanthoxylon fraxineum.*

Prickly Pear. One of the names of the *Opuntia* or Indian Fig.

Priest (A.-Sax. preost; Gr. πρεσβύτερος, *elder*). In Christian churches, a minister who presides over the spiritual affairs of a congregation. The word is by many regarded as representing the Greek *ἱερεύς*, who, like the Jewish priest, had both a sacrificial and mediatorial character; and this idea is embodied in the Catholic or sacerdotal theory of the Christian priesthood.

Primæ Viæ (Lat. *the first ways*). In

Medicine, a term employed to designate the stomach and bowels.

Primage. A certain allowance paid by the shipper or consigner of goods to the master and sailors of a vessel for loading the same. It varies in different places according to their respective customs.

Primary or **Primitive.** In Geology, rocks underlying the ordinary and recognisable fossiliferous rocks of a district have in the early days of geology been called by these names. The names assume that such rocks were formed before those which contain fossils; an assumption not at all safe, since many rocks distinctly igneous and plutonic are comparatively modern. There is no proof whatever that we have any of the primary or primitive rocks of the earth brought to the surface for our examination. Some are certainly very ancient, but they may have been modified from formations yet more ancient. The terms *hypogene*, *crystalline*, and *metamorphic* express simple facts of observation, and are far more convenient.

Primary Assemblies. A name applied to those assemblies in which all the citizens have a right to be present and to speak, as distinguished from representative parliaments. Primary assemblies are of necessity practicable only in small states, such as ancient Athens, and seem to require the existence of a dependent class shut out from all political privileges, and perhaps deprived even of personal liberty. On the other hand, they supply to the members a higher political education than that which is available for the generality of citizens in large states governed by representative parliaments. (Freeman's *History of Federal Government*, vol. i. ch. ii.)

Primary Colours. The principal colours into which a ray of white solar light may be decomposed or separated. Newton supposed them to be seven: red, orange, yellow, green, blue, indigo, and violet. Mayer considered some of these to be secondary colours, and that there are only three primary colours in the solar spectrum; namely, red, yellow, and blue, certain proportions of which constitute white light and all the other colours. (*Opera inedita*, 1775.) Dr. Young assumes red, green, and violet as the fundamental colours. (*Lectures on Nat. Phil.* p. 439.)

It is now known that every portion of the spectrum is a primary or pure colour, and cannot be resolved by further refraction; consequently it is erroneous to assume that some of the prismatic colours are produced by the superposition of others, as green by blue and yellow, orange by red and yellow, &c. [Chromatics; Light.]

Primate (Lat. primas, primatis). A prelate of superior dignity and authority. In England, the archbishop of York is entitled Primate of England; the archbishop of Canterbury, Primate of all England.

Primates (Lat.). The name given by Linnæus to the first order of animals in his *Systema Naturæ*, which associated man with the monkeys and bats, and corresponded to the Bimana, Quadrumana, and Cheiroptera of Cuvier.

Prime (Lat. primus, *first*). In Arithmetic, two numbers are said to be *prime* to each other, or one number is said to be prime to the other, when the two have no common measure except unity. A *prime number*, frequently termed *a prime*, is one which is not exactly divisible by any other number except itself and unity. In the theory of numbers, *complex primes* are also considered. [Integer.]

We are not yet in possession of any general method for finding primes, although there are many ways of detecting whether an assigned number is or is not prime. [Fermat's and Wilson's Theorems.] Vega's *Tables* give all primes less than 400,000.

For properties of prime numbers, see Fermat's edition of *Diophantus*; Euler's *Algebra*, and *Analysis Infinitorum*; Legendre, *Essai sur la Théorie des Nombres*; Barlow's *Elementary Investigations, &c.*; and especially the *Disquisitiones Arithmeticæ* of Gauss, of which there is a French translation by Delisle. Much useful information on the subject will also be found in Prof. J. S. Smith's Report on the Theory of Numbers in the *Proc. of Brit. Assoc.* for 1859–65.

Prime and Ultimate Ratios. A method of calculation invented by Newton, and employed in the *Principia*, being an extension and simplification of the ancient method of exhaustions. It may be thus explained: Let there be two variable quantities constantly approaching each other in value, so that their ratio or quotient continually approaches to unity, and at last differs from unity by less than any assignable quantity; the *ultimate ratio* of these two quantities is said to be a ratio of equality. In general, when different variable quantities respectively and simultaneously approach other quantities considered as invariable, so that the differences between the variable and invariable quantities become at the same time less than any assignable quantity, the ultimate ratios of the variables are the ratios of the invariable quantities or *limits*, to which they continually and simultaneously approach. They are called *prime ratios* or *ultimate ratios*, according as the ratios of the variables are considered as receding from, or approaching to, the ratios of the limits. (*Principia*, book i.)

Prime Vertical. In Astronomy, the vertical circle of the sphere which intersects the meridian at right angles, and passes through the east and west points of the horizon. In dialling, prime vertical dials are those which are projected on the plane of the prime vertical, or a plane parallel to it.

Primer. This word, signifying originally a religious work employed in the Roman Catholic service, is now generally used to denote the first book for children.

Primer. In Artillery, a small supplementary tube, used with the forty-pounder and

seven-inch screw breech-loading guns. It is placed in the horizontal part of the vent before the vent-piece is placed in the gun, its object being to communicate the flame from the ordinary tube to the cartridge.

Primer Seisin (Nor. Fr.). An ancient branch of the royal prerogative in England, by which it had possession for a year of the lands and tenements of which a tenant in capite died seised, if the heir was of full age; or, if not, until he was of age. [TENURE.]

Primine (Lat. primus, *first*). In Botany, the outermost sac or covering of an ovule; either composed of cellular tissue only, or traversed by numerous veins or bundles of tubes.

Priming (Lat. primus). In Architecture, the first coat of painting.

PRIMING. When the steam leaves a boiler, it carries over with it a certain quantity of water in little globules given off by the bubbles that come to the surface, and there burst. This quantity is sometimes very great when a large passage is opened, on account of the ebullition which frequently causes the water to pass over in the state of a substance resembling soap curds. The water so thrown off is technically said to *prime*. This is a great source of annoyance and loss of power.

Priming and Lagging. The alternate acceleration and retardation of the times of high water, caused by the combined action of the sun and moon. [LAGGING.]

Primipilus (Lat.). In Roman History, the name of the centurion of the first cohort of a legion, who had charge of the eagle. (Smith, *Dictionary of Greek and Roman Antiquities*, art. 'Exercitus;' *Mém. de l'Acad. des Inscr.* vol. xxxii.)

Primitiae (Lat.). The first fruits of any production of the earth, which were uniformly consecrated to the Deity by all the nations of antiquity. [FIRST FRUITS.]

Primitive (Lat. primitivus, *first of its kind*). In Geology. [PRIMARY.]

PRIMITIVE. In Grammar, a word neither derived from any other language, nor compounded from any other words of the same.

Primitive Colours. In Painting, these colours are red, yellow, and blue, from the mixtures of which other colours may be obtained—the secondary, and the tertiary; and by the addition of white or black, every variety of tint may be acquired.

Primitive, Complete. [DIFFERENTIAL EQUATIONS.]

Primitive Methodists. [RANTERS.]

Primitive Roots. In Algebra, an imaginary n^{th} root of unity is said to be *primitive* when it is not at the same time a root of unity of a lower order than the n^{th}. If $p_1, p_2 \ldots p_r$ denote the prime factors of n, then there are $n(1-\frac{1}{p_1})(1-\frac{1}{p_2})\ldots(1-\frac{1}{p_r})$ primitive n^{th} roots of unity. The successive powers $a, a^2, a^3, \ldots a^{n-1}$ of any one of these primitive roots constitute the complete series of n^{th} roots of 1. The successive powers of a non-primitive root, on the other hand, only yield a certain number of the complete set of roots. [ROOTS OF UNITY.]

In the theory of numbers, the roots of a binomial congruence $x^n \equiv 1$ (mod. p), where p is a prime number, which are not at the same time roots of any other congruence of the same form, and of lower degree, are also called *primitive roots appertaining to the exponent n*. Their number is the same as before, and equal to the number of primes less than n. As before, too, the characteristic property of the primitive roots of a congruence is that the residues of the successive powers of any one of them constitute the complete set of roots, primitive and non-primitive, of that congruence. Thus the congruence $x^4 \equiv 1$ (mod. 5) has the primitive roots 2 and 3, and the non-primitive roots 1 and 4. In fact, the successive powers of 2 are 2, 4, 8, 16, whose residues for the modulus 5 are respectively 2, 4, 3, 1. On the other hand, the powers of 4, viz. 4, 16, 64, 256, have the residues 4, 1, 4, 1, which do not exhaust the whole set of roots.

The above roots 2 and 3 are also called the primitive roots of 5, and generally the primitive roots of the congruence $x^{p-1} \equiv 1$ (mod. p) are called the *primitive roots of the prime number p*. The following determination of the primitive roots of 7 will further illustrate the general method; for further details, treatises on the theory of numbers must be consulted. From the series of numbers 1, 2, 3, 4, 5, 6, reject 1, 2, 4, which are quadratic residues; the numbers 3, 5, and 6 remain, of which 6, as being the residue of a cube, must be also rejected, when 3 and 5 will alone remain as primitive roots of 7. Desmarest, in his *Théorie des Nombres*, Paris 1852, has given a table containing the primitive roots of all primes less than 10,000.

Primogeniture. The right of the eldest son, and those who derive through the eldest son, to succeed to the property of the ancestor. Among ancient nations, the Jews alone appear, as far as is known, to have recognised this usage among their institutions. For some notice of the policy of the system of primogeniture, see SUCCESSION, LAW OF.

Primordial Utricle. In Vegetable Physiology, the first layer of protoplasm thrown down over the interior of a vegetable cell.

Primrose (from pryme rolles, its name in old books and MSS. &c. 'It is called Pryme Rolles of pryme tyme, because it beareth the first flowre in pryme time.' Chaucer writes it *primirole*). This common little plant affords an extraordinary example of blundering. Primirole is an abbreviation of Fr. primeverole, Ital. primaverola, dim. of prima vera, from fior di prima vera, the first spring flower. Primirole, as an outlandish unintelligible word, was soon familiarised into prime rolles, and thus into primrose. The rightful claimant of the name, strange to say, is the daisy. (Prior, *Names of British Plants.*) The common Primrose is the *Primula vulgaris* of botanists.

Primulaceæ (Primula, one of the genera). A natural order of herbaceous perigynous Exogens of the Cortusal alliance, inhabiting the northern and colder parts of the globe. It is nearly allied to all the regular Monopetalous orders, with a capsular superior fruit, especially to *Solanaceæ* and *Ericaceæ*, from both of which it is readily known by the stamens being placed opposite to the segments of the corolla. In this respect it agrees with *Myrsinaceæ*, which differ chiefly in their fleshy fruit and arborescent habit. The Cowslip, *Primula veris*, from which a sedative wine is made; the Primrose, *Primula vulgaris*; Auricula, *Primula auricula*; and the acrid *Cyclamen*, together with *Anagallis*, or the herb Pimpernel, which regularly closes its flowers at the approach of rain, are species of this order, which in its various genera, and in *Primula* especially, yields us many beautiful garden flowers.

Primum Mobile (Lat.). In the Ptolemaic Astronomy, the outermost sphere of the universe, which gives motion to all the others (i. e. those of the moon, planets, &c.), and carries them round with it in its diurnal revolution. Its centre is the centre of the earth.

Primuries or **Primary Quills** (*Primores*, Linn.). The largest feathers of the wings; they rise from the pinion-bones, or those corresponding to the metacarpus and digits.

Prince (from the Latin princeps, *first* or *foremost*; the German equivalent, fürst, has the same etymological signification). In England, this title is applied only to members of the royal family; and in no case, except that of the eldest son of the reigning king (prince of Wales), is it connected with a territorial distinction. On the Continent, the rank of princes is various; in France, under the old régime, the title belonged only to certain families of high distinction, connected with the royal blood; it ranks in Germany below that of duke.

Prince of Wales. The title bestowed by patent on the heir apparent to the crown of England. The origin of the title of prince of Wales is as follows: When Edward I. subdued Wales, he promised the people of that country, upon condition of their submission, to give them a prince who was born amongst them, and who could speak no other language. Upon their acquiescence with this deceitful offer, he conferred the principality of Wales upon his second son Edward, then an infant, born within the principality, and unable to speak any language. Edward, by the death of his elder brother Alfonso, became heir to the crown, and from that time this honour has been appropriated to the eldest sons of the kings of England. The earldom of Chester, which is likewise usually conferred upon the heir-apparent, was once a principality, and erected into that title by parliament in the 21st of Richard II.; it was then appointed to be given to the king's eldest son. But the whole Acts of that parliament were repealed in the reign of Henry IV., although the earldom has usually been since given with the principality of Wales. The prince of Wales, being the sovereign's eldest son, is by inheritance duke of Cornwall during the life of the sovereign, without any new creation, and the revenue of the present prince of Wales is chiefly derived from the income of the duchy of Cornwall, which at present amounts to upwards of 60,000*l.* a year (net). The accumulations at the prince's majority exceeded 600,000*l.* By stat. 26 Vict. c. 1, an annuity of 40,000*l.* charged on the consolidated fund is provided for the prince of Wales during the joint lives of himself and the queen. To compass the death of the prince of Wales, or violate the chastity of his consort, is high treason within the statute of 25 Edw. III. The prince of Wales has a household of his own, of which the chief officers are a comptroller and treasurer, keeper of privy seal, groom of the stole, &c.; besides another class of officers belonging to the duchy of Cornwall. By a statute of the Order of the Garter, issued in 1805, the prince of Wales was declared a constituent part of the original institution. Hence every prince becomes a knight of the Garter the moment he is created prince of Wales. For the constitutional question raised in 1788, respecting the right of the prince of Wales to the regency, see REGENT.

Prince's Metal. Prince Rupert's metal. The same as pinchbeck. An alloy of copper and zinc, a variety therefore of *brass*. It consists of seventy-five parts of copper and twenty-five parts of zinc.

Princeps Senatus (Lat.). Prince or first of the senate. In ancient Rome, the citizen whose name was inscribed first on the list of the senate by the censors was so called. This high dignity was not connected with any office, and was conferred, in later times, only on those who were recognised as the most considerable citizens of the state. Before the second Punic war, it seems to have belonged of right to the oldest of those who had held the office of censor; but the first deviation from this practice was in favour of Fabius Maximus. This title was the first germ of the imperial authority of Augustus. [SENATE.] There is a memoir on the subject in vol. xxiv. of the *Mémoires de l'Académie des Inscriptions*.

Principal (Lat. principalis, *chief*). In Architecture, this term is applied to the assemblage of timbers that form the support of a roof; these are commonly known and spoken of as *a pair of principals*. It is also applied to the main timber in an assemblage of carpentry; thus, in a roof the strong rafters used for trussing the beams are called *principal rafters*.

PRINCIPAL. In the Fine Arts, the chief circumstance in a work of art, to which the rest are to be subordinate.

PRINCIPAL. The name by which the heads of the Scottish universities, and of several colleges at the English universities, are distinguished.

Principal Axes. Through any point o of a solid body or system of material particles, three mutually rectangular lines can be so drawn that, when chosen as coordinate axes, the sums $\Sigma m y z$,

Σmzx, Σmzy, extended to all particles m of the system, severally vanish. These lines are termed the *principal axes* at the point o, and they exist, whatever the form of the body may be, and wherever the point o may be situated; their directions, however, vary with the position of this point according to a very beautiful law. To explain this it will be necessary to recall a few properties of MOMENT OF INERTIA and RADII OF GYRATION. Of all the axes passing through a given point, the principal axes correspond to the greatest and least moments of inertia; they might, indeed, be defined as the axes corresponding to the critical values of such moments. When the point under consideration is the centre of gravity, the principal axes take the name of *central*. The ellipsoid whose centre coincides with the centre of gravity, whose principal semi-axes have the same directions as the central principal axes, and the same magnitudes as the radii of gyration relative to these axes, is termed the *central ellipsoid of gyration*, and the system of quadric surfaces confocal with it serves to define the directions of the principal axes at all other points in space. In fact, if through any point o the three quadrics be drawn which are confocal with the central ellipsoid of gyration, they will intersect one another orthogonally in curves which, at the point o, will have precisely the directions of the principal axes. The principal axes at a point o, therefore, coincide with the axes of the quadric cone which has its vertex at o, and is circumscribed to the central ellipsoid of gyration.

A line taken at random will not in general be a principal axis at any one of its points. If it be so at one of its points, the latter is then termed its *principal point*, and the line is necessarily normal to one of the confocal quadrics through that point. Every line parallel to a central principal axis has a principal point where it intersects the plane of the other two central principal axes. The central principal axes are characterised by the property of being principal at each of their points.

When a body is symmetrical with respect to three rectangular planes, the latter always intersect each other in principal axes. Thus the principal axes at the centre of a homogeneous ellipsoid coincide with its geometrical axes. In the case of a spheroid the axis of rotation is one principal axis, but the other two are indeterminate. In the case of the sphere any three orthogonal lines through the centre are principal axes. For further properties of principal axes, see the memoirs of Prof. W. Thomson and the Rev. R. Townshend in the *Cambridge and Dublin Mathem. Jour.* vol. i.

Principal Normal. [NORMAL, PRINCIPAL.]

Principes (Lat.). The name given to one of the grand divisions of the Roman infantry. It was their duty to assume the initiative in an engagement, and from this circumstance their name is said to be derived. The other three bodies were the HASTATI, TRIARII, and VELITES.

Principle (Lat. principium). In Chemistry, a term sometimes applied to certain proximate components of organic bodies, such as *bitter principle, febrifuge principle, narcotic principle*, &c. This term, however, is now almost disused, it having been found that each bitter, febrifuge, narcotic, or other substance, generally contains a principle peculiar to itself upon which its powers depend, and that there is no such common or universal principle as was formerly supposed. For the same reason the term *principle of inflammability*, or *phlogiston*, is rejected, as applied in common with *nervous principle*, &c., to an imaginary existence.

Principles. In the Fine Arts, those general and fundamental truths from which the rules and maxims of art are deduced. To each art particular principles are attached on which its theory is founded. These principles, before they can be said to have stability, must be found to depend on certain truths, which, recognised by everyone, and indisputable, oblige the mind to concur in the deductions that result from them.

Pringlea (after Sir John Pringle, who wrote on scurvy). The Kerguelen's-land Cabbage is the sole representative of this genus of *Cruciferæ*, and is called *P. antiscorbutica* on account of its properties. The plant has a thick rhizome, often three or four feet long, which lies along the ground and bears at its extremity a large cabbage, closely resembling the common cabbage of this country, having a dense white heart and loose green outer leaves. The whole plant abounds with an essential oil, and when cooked, the cabbage tastes like tough mustard and cress. Being a powerful antiscorbutic, it is invaluable to the crews of ships touching at Kerguelen's land. Dr. Hooker says: 'During the whole stay of the "Erebus" and "Terror" in Christmas Harbour, daily use was made of this vegetable, either cooked by itself or boiled with the ship's beef, pork, or pea-soup. The essential oil gives a peculiar flavour, which the majority of the officers and the crew did not dislike, and which rendered the herb even more wholesome than the common cabbage; for it never caused heartburn, nor any of the unpleasant symptoms which that plant sometimes produces.'

Printing (Fr. empreinte, imprimerie, typographie; Ger. Buchdrückerkunst). Letter-press printing, to which this article is confined, is the art of taking impressions from types and engravings in relief.

HISTORY.—The art of printing in Europe is of comparatively modern origin, only 400 years having elapsed since the first book, properly so called, issued from the press; but we cannot doubt that its rudiments were known to the ancients. It was certainly practised in the East from a very early period, and in a manner similar to our own first attempts. That a rude kind of printing was known to the Assyrians is evident from undecayed bricks which have been found stamped with various symbolical and hieroglyphic characters; but, as the stamp itself was in one piece or block, it

seems to have been inapplicable to the propagation of knowledge.

This primitive mode of printing is continued to the present time by the Chinese. Their earliest attempts are stated in the chronicles to have been made about fifty years before the Christian era; but it was not till the reign of the emperor Ming-tsong (927–934 A. D.) that any great advance was made in printing large numbers of comparatively cheap books. The name of the printer was Tong-tao. He obtained permission of the emperor in 932 to print and circulate copies of the 'Classical Works' as they are called, by taking impressions from stone plates, the letters being cut into them, so that the impression on the paper was black, and the letters themselves were left white. This is still the case in all Chinese lithographic printing. Tong-tao, however, subsequently obtained the emperor's sanction to cut in wood and print an edition of the nine 'King,' or classical books, for the use of the imperial college in Pekin. This was completed in 952; and, although intended only for the pupils of the college, it was allowed to be purchased by any person in the empire. The process pursued in the printing of this work is precisely the same as that which is practised at the present day; the following being the modus operandi: The work intended to be printed is handed to a calligraphist, who writes the separate pages on fine tracing paper; these are given to the engraver, who glues them face downwards upon a thin plate of hard wood, called *li*, resembling that of the pear-tree, and he cuts away with a sharp instrument all those parts of the wood on which nothing is traced, leaving the transcribed characters in relief and ready for printing. The Chinese printer then, having no notion of the printing press, makes use of two fine brushes, both held in the right hand, one of which contains ink, the other being dry. With the former he blackens the letters; the latter he passes gently over the paper which has been laid on them. By this means an expert workman can take a large number of impressions in one day. As the Chinese paper is thin and transparent, it is printed on one side only, two pages side by side, and the sheet has a black line down the middle, as a guide to the binder, who folds it double and fastens the open leaves together. Various attempts have been made in the Celestial Empire to substitute movable types for the wooden blocks, but they have always terminated in a return to the old method.

The ancient Romans made use of metal stamps, with characters engraved in relief, to mark their articles of trade and commerce; and Cicero, in his *De Naturâ Deorum*, has a passage from which Toland imagines the moderns have taken the hint of printing. Cicero orders the types to be made of metal, and calls them *formæ literarum*, the very words used by the first printers. In Virgil's time, too, brands, with letters, were used for marking cattle, &c., with the owner's name. Landseer, in his *Lectures on the Art of Engraving*, 8vo. 1807, observes, 'Had the modern art of making paper been known to the ancients, we had probably never heard the names of Faust and Finiguerra; for with the same kind of stamps which the Romans used for their pottery and packages, books might also have been printed; and the same engraving which adorned the shields and pateras of the more remote ages, with the addition of paper might have spread the rays of Greek and Etrurian intelligence over the world of antiquity. Of the truth of this assertion I have the satisfaction to lay before you the most decided proofs, by exhibiting engraved Latin inscriptions, both in cameo and intaglio, from the collection of Mr. Douce, with impressions taken from them at Mr. Savage's letter-press but yesterday [1805]. One of them is an intaglio stamp with which a Roman oculist was used to mark his medicines; the other, which is of metal, and in cameo, is simply the proper name of the tradesman by whom it has probably been used, "T[iti] Valagini Mauri."' The cut exhibits a fac-simile of the latter stamp.

Books before the Invention of Printing.—The value of books, and the esteem in which they were held before the invention of printing, were such, that notaries were employed to make the conveyance with as much care and attention as if estates were to be transferred. It was then thought the worthy occupation of a life either to copy or collect an amount of reading which modern improvements now present to us for a few shillings. Galen tells us that Ptolemy Philadelphus gave the Athenians fifteen talents, with exemption from all tribute, and a great convoy of provisions, for the autographs and originals of the tragedies of Æschylus, Sophocles, and Euripides. 'Pisistratus is said to have been the first among the earliest of the Greeks who projected an immense collection of the works of the learned, and is supposed to have been the collector of the scattered works which passed under the name of Homer.' (D'Israeli, *Cur. of Lit.*)

Among the Romans the bulk or goodness of a man's library was the distinguishing mark of his excellence and wisdom. Middleton (*Life of Cicero*), speaking of Cicero, says, 'Nor was he less eager in making a collection of Greek books, and forming a library, by the same opportunity of Atticus's help. This was Atticus's own passion; who, having free access to all the Athenian libraries, was employing his slaves in copying the works of their best writers, not only for his own use, but for sale also, and the common profit both of the slave

and the master; for Atticus was remarkable, above all men, for a family of learned slaves, having scarce a foot-boy in his house who was not trained both to read and write for him. By this advantage he had made a very large collection of choice and curious books, and signified to Cicero his design of selling them; yet seems to have intimated withal, that he expected a larger sum for them than Cicero would easily spare; which gave occasion to Cicero, to beg of him in several letters, to reserve the whole number for him, till he could raise money enough for the purchase. "Pray keep your books (says he) for me, and do not despair of my being able to make them mine; which if I can compass, I shall think myself richer than Crassus, and despise the fine villas and gardens of them all." Again, "Take care that you do not part with your library to any man, how eager soever he may be to buy it; for I am setting apart all my little rents to purchase that relief for my old age."'

In the year 1274 the price of a Bible, in 9 volumes, 'fairly written,' with a glossary or commentary, was 50 marks, or 33*l.*; and in 1433, the cost of transcribing the works of Nicholas de Lira, in 2 vols., 'to be chained in the library of the Grey Friars,' London, was 66*l.* 13*s.* 4*d.* This shows the enormous cost of books before the discovery of printing; for, if we take the money of those times to be twenty times its present value, the Bible must have been worth 660*l.*, and De Lira 1,333*l.* 6*s.* 8*d.* The pay of a labouring man in 1272 was 1½*d.* a day. (Dugdale's *Warw.*; Stow; Rymer's *Fœdera.*)

Among other writers on this subject, Mr. Watson, in his *History of Printing*, refers us to an epistle of Antonius Bononia Becatellus, surnamed Panorme, to Alphonsus king of Naples and Sicily, lib. v. Epist. *Significasti mihi nuper ex Florentia, &c.* 'You lately wrote to me from Florence, that the works of Titus Livius are there to be sold, in very handsome books; and that the price of each book is 120 crowns of gold: therefore I intreat your majesty, that you cause to be bought for us Livy, whom we use to call the king of books, and cause it to be sent hither to us. I shall in mean time procure the money, which I am to give for the price of the book. One thing I want to know of your prudence, whether I or Poggius have done best; he, that he might buy a country-house near Florence, sold Livy, which he had writ in a very fair hand; and I, to purchase Livy, have exposed a piece of land to sale: your goodness and modesty have encouraged me to ask these things with familiarity of you. Farewell, and triumph.'

Nor was it in Italy alone that books were valued at immense prices, but in France also, as appears by a letter of Gaguin to one of his friends who had sent to him from Rome to procure a Concordance for him: 'I have not to this day found out a Concordance, except one, that is greatly esteemed; which Paschasius, the bookseller, has told me is to be sold, but the owner of it is abroad; and it may be had for a hundred crowns of gold.' Mr. Ames had a folio manuscript in French verse called *Romans de la Rose* (whence Chaucer's translation), on the last leaf of which is written, *Cest lyuir costa au palas de Parys quarante coronnes dor, sans mentyr*; i.e. This book cost at the palace of Paris 40 crowns of gold, without lying (about 33*l.* 6*s.* 6*d.* sterling).

Brassicanus says, 'The emperor Frederick III. knew no better gratuity for John Capnion, who had been sent to him on an embassy by Edward of Wittemberg, tha' by making him a present of an old Hebrew Bible.'

Another instance of the high estimation in which books were held in old times, is to be seen in the front of the manuscript Gospels belonging to the public library of the university of Cambridge, written in an old hand in Latin and Anglo-Saxon, given to the university by the learned Theodore Beza. 'This book was presented by Leofric, bishop of the church of St. Peter's in Exeter, for the use of his successors.' This Leofric was chancellor of England in the reign of Edward the Confessor, and died in 1071 or 1072.

About the time of King Henry II. the manner of publishing books was to have them read over for three days successively before one of the universities, or before other judges appointed by the public; and, if they met with approbation, copies of them were then permitted to be taken. These copies were usually written by monks, scribes, illuminators, and readers brought or trained up to that purpose for their maintenance. The orders respecting books in the 'Close Rolls' of the middle ages are interesting, not only as illustrating the literary taste of the age, but principally because they generally contain some circumstance which shows the scarcity and value of the article.

The passion for the enjoyment of books has in all ages led their lovers to cover them with the most costly and ornamental bindings. The ancients commonly adorned them with pendent ornaments of variously coloured cloth, and the covers were stained with scarlet or purple colour: 'Hirsutus sparsis ut videare comis' (*Ovid*), and 'Purpureo fulgens habitu, radiantibus uncis' (*Martial*). The *unci* were rollers of wood or ivory, round which the books were rolled to prevent injury to their fronts. Ovid and Tibullus call them *cornua*, from the similarity of their ends to horns. Epistles differed from books in this: the leaves were folded together, tied round with linen tape, and sealed with *creta Asiatica*, while books were 'bound' as above. If, however, there were more epistles than one, 'or if one epistle was to be preserved in the library, it was enclosed and turned round, and not folded: hence the word *volumen*' (*Arts of the Greeks and Romans*).

Block Books.—Block books must be regarded as the immediate precursors of printing. The art of printing books from engraved blocks of wood was without doubt invented in Holland. Apart from the great interest created by the

object for which the block books were designed, namely, the propagation of the Scriptures, they are extremely valuable as exhibiting the first attempts at engraving on wood in the form of books, many of them having preceded the art of printing by movable types. (Sotheby's *Block Books.*)

That prints without text, or *letterpress*, as it is termed, were in common use at a period considerably anterior to that of the block books, there is abundant evidence. It is related by Papillon (*Traité Historique et Pratique de la Gravure en Bois*) that the heroic actions of Alexander the Great were engraved on wood by the two Cunio, Alexander Alberic, and his sister Isabella, and impressions printed from tho blocks, as early as 1285; and his statement has been supported by Ottley (*Early Hist. of Engraving upon Copper and Wood*, &c. 2 vols. 4to. 1816) and Singer (*Hist. of Playing Cards, &c.* London, 4to. 1816). But Jackson (*Hist. of Wood Engraving*) takes some trouble to prove that Papillon was excessively credulous, if not deranged. Playing cards were engraved and printed from blocks towards the end of the fourteenth century or probably earlier. The print of St. Christopher carrying the infant Saviour on his back across the sea, in the collection of Earl Spencer, bears an inscription and the date 1423 at the bottom of the same block; but one in the possession of Mr. J. A. O. Weigel of Leipsic (a copy of which may be seen in Sotheby's *Block Books*, vol. ii. p. 161), is supposed to be the work of even an earlier artist. These circumstances, together with the fact that the government of Venice published a decree, dated October 11, 1441, wherein the art and mystery of making 'playing cards and coloured figures printed' are stated to have fallen into decay in consequence of the great quantity which had been made out of that state, and which were now prohibited under pain of forfeiture and fine, all prove that the knowledge and practice of printing, although not applied to the spread of knowledge and the multiplication of books, had yet an existence in Europe long before the time to which it is usually attributed. This Venetian decree may be regarded as the earliest authentic document respecting printing.

Great numbers of books were produced in the Chinese manner above described: for the diversity of the characters found in block books has been a never-ending puzzle to those who have endeavoured to ascertain the printer by comparing the forms of the letters used. The workmanship of many of these picture books was coarse, without shadowing or 'cross-hatching,' tastelessly daubed over with broad colours, especially those which were printed for circulation amongst the poorer classes. The best known works of this class were called *Biblia Pauperum*, poor men's books, or rather books for poor preachers, and consisted of a series of rude engravings, each occupying a page on one side of the leaf only, and divided into compartments containing pictorial illustrations of the most remarkable incidents mentioned in the books of Moses, the Gospels, and the Apocalypse. A copy of the *Biblia Pauperum* in the British Museum is supposed by Heinecken (*Idée Générale, &c.* p. 292) to be the first edition. The cuts are coloured by hand.

Invention of Movable Types.—About the year 1438, while the learned Italians were eagerly deciphering their recently discovered MSS., and slowly circulating them from hand to hand, it fell to the lot of a few obscure Germans to perfect the greatest discovery recorded in the annals of mankind. The notion of printing by movable types, and thereby saving the endless labour of cutting new blocks of letters for every page, was reserved for John Gutemberg of Mentz. Born in that city about the beginning of the century, he settled at Strasburg about 1424, and commenced printing in the house of one Dritzehen. But having been engaged in a lawsuit connected with Dritzehen's family, and exhausted his means, he returned to Mentz, where he resumed his typographic employment in partnership with a wealthy goldsmith, named John Fust or Faust. After many experiments with his presses and movable types, Gutemberg succeeded in printing an edition of the Vulgate, the Mentz or Mazarin Bible, so called from a copy having been discovered in the library of Cardinal Mazarin in Paris. The work was done between the years 1450 and 1455, and was printed on vellum; but there are several paper copies in England, France, and Germany. The partnership between Gutemberg and Fust having been dissolved, and the former being unable to repay part of the capital advanced by the wealthy goldsmith, the whole of the printing apparatus fell into the hands of Fust, who, says D'Israeli (*Cur. of Lit.*), 'printed off a considerable number of copies of the Bible, to imitate those which were commonly sold as MSS.; and he undertook the sale of them at Paris. It was his interest to conceal this discovery, and to pass off his printed copies for MSS. But, enabled to sell his Bibles at sixty crowns, while the other scribes demanded five hundred, this raised universal astonishment; and still more when he produced copies as fast as they were wanted, and even lowered his price. The uniformity of the copies increased the wonder. Informations were given in to the magistrates against him as a magician; and in searching his lodgings a great number of copies were found. The red ink—and Fust's red ink is peculiarly brilliant—which embellished his copies, was said to be his blood; and it was solemnly adjudged that he was in league with the infernals. Fust at length was obliged, to save himself from a bonfire, to reveal his art to the parliament of Paris, who discharged him from all prosecution in consideration of the wonderful invention.' This Bible was printed with large *cut* metal types; but in 1457 a magnificent edition of the *Psalter* appeared, printed by Fust and his assistant and son-in-

law, Peter Schœffer, who had been taken into partnership. In this book the new invention was announced to the world in 'a boasting colophon,' though certainly not unreasonably bold. Another edition of the *Psalter*, one of an ecclesiastical book, Durand's account of liturgical offices (*Rationale Divin. Officiorum*), one of the Constitutions of Pope Clement V., and one of a popular treatise on general science, called the Catholicon (*Catholicon Januensis*, *1460*), filled up the interval till 1462, when the second Mentz Bible proceeded from the same printers. This, in the opinion of some, is the earliest book in which *cast* metal types were employed: those of the Mazarin Bible having been cut with the hand. But this is a controverted point. In 1465 Fust and Schœffer published an edition of Cicero's *Offices*, the first tribute of the new art to polite literature. (Hallam, *Europe during the Middle Ages*, vol. iii. p. 470.)

After the lapse of a few years the pupils and workmen of Fust and Schœffer were dispersed into various countries by the sacking of Mentz under the Archbishop Adolphus, and the invention was thereby publicly made known, and the art spread over all parts of Europe. Before the year 1500, printing presses had been set up in 220 places, and a multitude of editions of the classical writers given to the world. From Mentz the art was transplanted to Haarlem and Strasburg; from Haarlem to Rome, in 1466, by Sweynheym and Pannartz, who were the first to make use of Roman types; to Paris in 1469; to England in 1474; and to Spain in 1475. So rapid indeed was the spread of the art, that, between the years 1469 and 1475, most towns in Germany, Italy, and the Netherlands had made successful attempts in the production of printed copies of the most valued authors of the time. Santander, in his interesting and masterly work, *Dictionnaire Bibliographique choisi du Quinzième Siècle, &c.* (Bruxelles 1805, 3 vols.), gives at the end of his first volume, the following chronological table of 200 places where the art was practised during the fifteenth century, with the names of the printers and of the first productions of their presses. This table is given, not only because it is curious, but because bibliographers are enabled to see at a glance the editiones principes of the fifteenth century.

Chronological Table of the Towns, Monasteries, &c. in which the Art of Printing was practised in the Fifteenth Century; giving the first portion of the Titles of the First Impressions, with their Date in each Place, together with the Printers' Names.

N.B.—The Figures in Parentheses indicate the Date of the Impressions in which the Printer's Name appears for the First Time.

Dates	Names of Towns, &c.	First Impression with Certain Date	Names of the First Printers
1457	Mentz	Psalmorum codex, folio	Joan. Fust et Petrus Schœffer.
1461	Bamberg	Recueil de fables, germanicè, folio	Albert Pfister.
1465	Subbiaco	Lactantii opera, 4to	Conradus Sweynheym et Arnoldus Pannartz.
1467	Rome	Ciceronis epistolæ ad familiares, 4to	The same printers.
1467	Elfeld	Vocabularium ex quo, 4to	Henry et Nic. Bechtermuntze et Wigandus Spyes.
1467	Cologne	S. August. de Singul. clericor., 4to	Ulricus Zell, or Zell d'Hanau.
1468	Augsburg	Meditationes vitæ Christi, folio	Ginther Zainer, de Reutlingen.
1469	Venice	Ciceronis epistolæ ad familiares, folio	Joannes de Spira.
1469	Milan	Miracoli de la glor. V. Maria, 4to	Philippus de Lavagna.
1470	Nuremberg	Comestorium vitiorum, folio	Joannes Sensenschmidt (1472).
1470	Paris	Epistolæ Gasparini Pergamensis, 4to	Ulricus Gering, M. Crantz et M. Friburger, de Colmar.
1470	Foligno	Leon. Aretini de Bello Italico, folio	Emilien de Orfinis.
1470	Treves	Hist. de indulgentia B. Francisci, 4to	Joan. Reynardi.
1470	Verona	La Batracomyomachia, folio	Joan de Verona (1472).
1471	Strasburg	Gratiani decretum, folio	Joan. Mentelius (1473).
1471	Spires	Postilla super Apocalypsim, 4to	Petrus Drach (1477).
1471	Treviso	Mercurius Trismegistus, 4to	Gerardus de Lisa, de Flandria.
1471	Bologna	Ovidii opera, folio	Balthasar Azzoguidi.
1471	Ferrara	Martialis epigram, 4to	Andreas Belfortis.
1471	Naples	Bartholi de Saxo Ferrato lectura, folio	Sixtus Riessinger, de Strasburg.
1471	Pavia	Joann. Matthæi de Gradibus opera medica, folio	Anton. de Carcano (1476).
1471	Florence	Comment. Servii in Virgil., folio	Bernard Cennini and son.
1472	Cremona	Angeli de Perusio lectura, folio	Dion. de Paravesino et Steph. de Merliniade Leucho.
1472	Fivizano	Virgilius, folio	Jacobus, Baptista Sacerdos et Alexander.
1472	Padua	La Fiammetta di Boccaccio, 4to	Barth. de Valdesochio et Mart. de Septem Arboribus.
1472	Mantua	Tractatus Maleficiorum, folio	Petrus-Adam de Michaelibus.
1472	Montereale	S. Antonini de instruct. confes., 4to	Ant. Mathiæ de Antuerpia et Balthasar Corderius.
1472	Jesi	Commedia di Dante, folio	Fridericus Veronensis.
1473	Munster, in Argau	Roderici speculum, folio	Helias Helye, or de Louffen.
1473	Parma	Trionfi di Petrarca, folio	Andreas Portiglia.
1473	Brescia	Statuta Brixiæ, folio	Thomas Ferrandus.
1473	Messina	Vita di S. Hieronimo, 4to	Henricus Alding.
1473	Ulm	Opus de mysterio missæ, 4to	Joan. Zainer, de Reutlingen.

Dates	Names of Towns, &c.	First Impression with Certain Date	Names of the First Printers
1473	Buda	Cronica Hungarorum, folio	Andreas Hess.
1473	Laugingen	S. Aug. de Consensu Evangelistarum, fol.	No printer's name.
1473	Mersburg	S. Aug. de Quæstionibus Orosii, 4to	Lucas Brandis.
1473	Alost	Speculum conversionis peccator., 4to	Theodoricus Martens.
1473	Utrecht	Historia scholastica novi Testam., folio	Nicolas Ketelaer et Ger. de Leempt.
1473	Saint Ursio	J. Duns Scotus super tertio sententiarum, folio	Joannes de Rheno.
1474	Vicenza	Dita mundi, folio	Leonardus Achates, de Bâle.
1474	Como	Tractatus de appellationibus, folio	Ambrosius de Orcho et Dionys. de Paravicino.
1474	Turin	Breviarium romanum, 8vo	Joh. Fabri et Joanninus de Petro.
1474	Genoa	Summa Pisanella, folio	Matthias Moravus et Mich. de Monaco.
1474	Savona	Boëthius de Consol. philosophiæ, 4to	Bonnus Johannes.
1474	Eslingen	Th. de Aquino in Job., folio	Conradus Fyner.
1474	Basle	Der Sassen Spiegel, folio	Bernardus Richel.
1474	Val Sainte Marie	Breviarium Moguntin., 4to	Fratres Vitæ Communis.
1474	Valencia	Trobes de la S. V. Maria, 4to	Alonso Fernandez de Cordova et L. Palmart (1478).
1474	Louvain	Commoda ruralia, folio	Joannes de Westphalia.
1474	Westminster	The Game and Playe of the Chesse, folio	William Caxton.
1475	Lubeck	Rudimentum Novitiorum, folio	Lucas Brandis, de Schass.
1475	Burgdorff	Tractatus de apparitionibus, folio	No printer's name.

The first book in which Greek types occur is Cicero's *Offices*, printed in the year 1465, in which the characters are so imperfect that the words are with difficulty deciphered; but the first work printed wholly with Greek types is a Greek Grammar written by the learned Constantine Lascaris, printed in Milan by Dionysius Paravisinus, in 1476, in 4to. It went through several editions in Italy, France, and Switzerland. One of them, that of Aldus, printed in Venice in 1495, is the first Aldine book printed with a date. One of the most elegant specimens of ancient Greek typography, valued not only for its beauty, but also for its rarity and the accuracy of its text, is the *Argonautica*, Flor. ap. Junta, 1500, 4to. editio princeps. It was not unusual for the early printers of Greek as well as of other works, to endeavour to imitate the characters of the MSS. of the age. In this they were more or less successful. An exceedingly beautiful specimen of this kind of printing is the editio princeps of Isocrates, *Orat. à Demetrio Chalcondyla*, Gr. Mediol. ap. Henr. Germanus et Sebastianus ex Pontremula, 1493, fol. The text of this edition is said to be remarkably accurate. Fabricius considers it more exact than that of the Aldine edition of 1513. The first Greek book printed in Rome was *Pindari Opera*, Gr. cum Scholiis Calliеggi, Rome, 1515, 4to. This is also remarkable as the first edition with the Scholia. The first Greek work printed at Cambridge was Plato's *Menexenus, sive Funebris Oratio, exhortatio ad Patriam amandam atque defendendam*, Cantab. Greek types were not introduced into Scotland till after the middle of the sixteenth century. In a 4to. volume printed at Edinburgh in 1563, entitled, *The Confutation of the Abbote of Crosraguel's Masse*, there is an Epistle from the Printer to the Reader, apologising for his want of Greek characters, which he was obliged to supply by manuscript. The first work printed with Roman types was Cicero's *Epistolæ ad Familiares*, by Sweynheym and Pannartz, at Rome, in 1467. Italic type was invented by Aldus Manutius, about 1500. Italy has the honour also of having printed the first Hebrew Bible, at Soncino, a small city in the duchy of Milan, in 1488, under the superintendence of two Jewish rabbins, named Joshua and Moses. The edition of Brescia, of 1494, was used by Luther in making his German translation. But Hebrew types were not introduced into England for many years after this period; for we find that in 1524, Dr. Robert Wakefield, chaplain to Henry VIII., complains, in his *Oratio de Laudibus*, &c., that he was obliged to omit his whole third part, as the printer (Wynkyn de Worde) had no Hebrew types. Towards the end of the sixteenth century, various works were printed in Syriac, Arabic, Persian, Armenian, and Coptic, or modern Egyptian types; some to gratify the curiosity of the learned, and others for the liturgic uses of the Christians in the Levant.

Printing in England.—Until about the period of the Restoration, William Caxton was universally acknowledged to have introduced the art of printing into this country, in or about the year 1471. But, in 1664, Richard Atkyns, in a work called *The Original and Growth of Printing, &c.*, brought before the notice of the curious a little book, printed at Oxford, bearing the date 1468, three years before the period usually assigned to the labours of Caxton. This work took literary men by surprise, and gave rise to the most violent discussions. It is related by Atkyns that a Dutchman of the name of Frederic Corsellis was induced to desert his employers in the Low Countries, and that one Richard Turnour, an agent of King Henry VI., assisted by William Caxton, who was well known in Holland as a merchant and therefore likely to throw the jealous possessors of the new art off their guard, brought him to England, where at Oxford he was set to work by Archbishop Bourchier, ten years before the date of Caxton's first book. The title of Corsellis' volume is *Exposicio Sancti Jeronimi in Simbolum Apostolorum ad Papam Laurentiam*. And at the end *Explicit Exposicio, &c.* Impressa *Oxoniæ, et finita anno Domini* MCCCCLXVIII. XVII. *die Decembris*. The silence of Caxton, however, on a subject in which he took the utmost interest, and on a transaction in which he is said to have been an important actor, is a strong argument against the authenticity of the story. Indeed, M. Santander (vol. i. p. 328) does not for a moment entertain the pretensions of Corsellis, and agrees with Dr. Middleton in considering that the date MCCCCLXVIII. ought to have been MCCCCLXXVIII., an X having been by accident omitted by the compositor: 'Voilà ce que Richard Atkyns imagina, et les moyens dont il se servit, en 1664, pour soutenir contre le corps des libraires de Londres, que l'imprimerie était un droit de la

couronne en Angleterre. Mais le docteur Middleton, dans sa *Dissertation sur l'Origine de l'Imprimerie en Angleterre*, imprimée à Cambridge en 1735, in 4°, a prouvé démonstrativement que l'impression d'Oxford, de *l'Expositio S. Jeronimi in Simbolum Apostolorum*, est de l'an 1478, le compositeur ayant omis un X dans la date de la souscription (faute typographique dont nous avons plusieurs exemples dans les impressions du XV° siècle).' In a Bible at Augsburg, the last two figures in the date 1449 have been transposed, and should stand 1494. Other mistakes of a like nature are mentioned by Chevillier, Orlandi, Koelhoff, and Palmer; and amongst other similar blunders Dr. Middleton points out the following: 'Whilst I am now writing, an unexpected instance has fallen into my hands, to the support of my opinion; an *Inauguration Speech of the Woodwardian Professor, Mr. Mason*, just fresh from the press, with its date given ten years earlier than it should have been, by the omission of an X, viz. MDCCXXIV.; the very blunder exemplified in the last piece printed at Cambridge, which I suppose to have happened in the first from Oxford.'

Whether, however, Caxton was or was not the first English printer, it is quite certain that he was the first who made use of cast metal types, the works of Corsellis having been executed with merely wooden ones. During a long residence abroad, he had acquired a practical knowledge of the art; and on his return to England in 1471, set up a press in an old chapel of Westminster Abbey; and was for many years engaged in translating and printing books on a variety of subjects. His first work is, *Le Recueil des Histoires de Troyes* of Raoul le Fèvre, chaplain to the duchess of Burgundy; but *The Dicts and Sayinges of the Philosophers* is the earliest book known to have issued from his press with the date and place of printing; and we have no proof whatever that his six earlier works were printed in this country. Indeed it is stated in the life of Caxton, in Ames's *Typ. Antiquities*, p. xcv., that the French and English editions of the *Histories of Troy* are justly 'admitted to have been printed abroad.'

Caxton's types, as well as those of most of the early printers, were the Gothic, or black letter characters, mixed with a kind of secretary hand, and having the characteristics found in English MSS. of a period anterior to the Conquest. A facsimile of his types is here given from the dedication to the *Game and Playe of the Chesse*, showing the formation of his letters, and proving to our mind that, as compared with those of the Oxford printer Corsellis, they have an undoubted claim to greater antiquity.

To the right noble/right excellent & vertuous prince George duc of Clarence Erle of warwyk and of salisburye/grete chamberlayn of Englond & leutenant of Irelond oldest broder of kynge Edward by the grace of god kynge of England and of france /

It will be seen that Caxton's *d* at the end of a word is very singular, resembling the letters in the MSS. referred to; and that, instead of commas and periods, he used an oblique stroke thus /, still used in German books. Like other printers of his time, he never used any direction or catch words, and rarely numbered his leaves, and never his pages. He distinguished his books by a device, consisting of the initial letters of his name and a cypher for 74, the date of his introduction of the art into England.

Caxton is said to have printed 64 books; and was followed by his pupils or assistants, Theodore Rood, John Lettou, William Machilinia, and Wynkyn de Worde, all foreigners, and Thomas Hunt, an Englishman. All these pioneers of the art worthily maintained the honour of their master's name; and Wynkyn de Worde is especially remarkable for his improvements and typographical excellence, and as having been the first printer in England who introduced the Roman letter. He printed 410 works.

The spirit and taste of the patrons of the first printers are shown in the character of their earliest works, religious books and romances constituting the greater part of the productions of the father of English printing. But the art, although at first countenanced by the clergy, was soon looked upon with extreme jealousy by the hierarchy. Efforts were made towards the publication of the Bible; but for the first sixty or seventy years all copies of the Scriptures were printed in the Latin or some other language not understood by the generality of the people. A new era had, however, arrived. The doctrines of the Reformation had inspired the people with a strong desire to possess Bibles. Wickliffe's translation was never printed. The part of the Sacred Writings in the English language first produced by the printing press, was the New Testament, translated by William Tindal, assisted by Miles Coverdale, afterwards bishop of Exeter: it was printed at Antwerp, in 1526; but as it gave offence to Wolsey and the clergy, the whole impression was bought up and burnt. The first complete English Bible printed by authority, was Tindal's version, revised and compared

with the original by Coverdale, and afterwards examined by Cranmer, who wrote a preface for it. Of this edition, hence called 'Cranmer's Bible,' 500 copies were printed by Grafton and Whitchurch, to whom Henry VIII., in letters patent dated November 13, 1539, granted the sole right of printing the Bible for five years. It was ordered by royal proclamation to be set up in all churches throughout the kingdom, under a penalty of 40*s.* a month in every case of neglect. So great was the demand for copies of the Scriptures in the sixteenth century, that we have in existence 326 editions of the English Bible, or parts of the Bible, printed between 1526 and 1600.

The progress of the art in the first century of its existence was remarkable; but the earliest English printers did not attempt what the Continental ones were doing for the ancient classics. 'Down to 1540, no Greek book had appeared from an English press; Oxford had only printed a part of Cicero's epistles; Cambridge, no ancient writer whatever. Only three or four old Roman writers had been reprinted, at that period, throughout England. But a great deal was done for public instruction by the course which our early printers took; for, as one of them says: "Divers famous clerks and learned men translated and made many noble works into our English tongue, whereby there was much more plenty and abundance of English used than there was in times past." The English nobility were, probably, for more than the first half-century of English printing, the great encouragers of our press: they required translations and abridgements of the classics, versions of French and Italian romances, old chronicles, and helps to devout exercises. Caxton and his successors abundantly supplied these wants, and the impulse to most of their exertions was given by the growing demand for literary amusement on the part of the great. Caxton, speaking of his *Boke Eneydos*, says: "This present book is not for a rude uplandish man to labour therein, nor read it; but only for a clerk and a noble gentleman, that feeleth and understandeth in feats of arms, in love, and in noble chivalry." But a great change was working in Europe; the "rude uplandish man," if he gave promise of talent, was sent to school. The priests strove with the laity for the education of the people; and not only in Protestant but in Catholic countries schools and universities were everywhere founded. Here, again, was a new source of employment for the press—A, B, C's, or Absies, Primers, Catechisms, Grammars, Dictionaries, were multiplied in every direction. Books became, also, during this period, the tools of professional men. There were not many works of medicine, but a great many of law. The people, too, required instruction in the ordinances they were called upon to obey; and thus the statutes, mostly written in French, were translated and abridged by Rastell, our first law-printer.

'After all this rush of the press of England towards the diffusion of existing knowledge, it began to assist in the production of new works, but in very different directions. Much of the poetry of the sixteenth century, which our press spread around, will last for ever: its controversial divinity has, in great part, perished. Each, however, was a natural supply, arising out of the demand of the people; as much as the chronicles, and romances, and grammars were a natural supply; and as the almanacks, and mysteries, and ballads, which the people then had, were a natural supply. Taken altogether, the activity of the press of England, during the first period of our enquiry, was very remarkable. Ames and Herbert have recorded the names of 350 printers in England and Scotland, or of foreign printers engaged in producing books for England, that flourished between 1471 and 1600. The same authors have recorded the titles of nearly 10,000 distinct works printed amongst us during the same period. Many of these works, however, were only single sheets; but, on the other hand, there are, doubtless, many not here registered. Dividing the total number of books printed during these 130 years, we find that the average number of distinct works produced each year was 75.' (*Penny Magazine.*)

In the sixteenth century the broils consequent on the Reformation, although that event stimulated religious enquiry, did much to impede the progress of the art in England. But the civil wars and the gloomy religious spirit which succeeded to the pedantry and verbal criticism of the reign of James I., and which prevailed till the Restoration, interrupted still more the production of works calculated to cultivate the understanding. Indeed, we cannot but regard this period as the least favourable to the diffusion of knowledge of any period in the history of our literature. In the British Museum is a collection of controversial and quibbling tracts amounting to the enormous number of 30,000, while the impressions of new books printed during these stormy times were very few. Dr. Johnson has well remarked that the nation, from 1623 to 1664, was satisfied with two editions of Shakspeare's plays, which, probably, together did not amount to a thousand copies. But during this period we must not forget the present authorised version of the Bible, translated by the forty-seven distinguished scholars appointed by James I., and printed in 1611, which is allowed by competent judges to be one of singular merit, and indeed the most perfect ever produced. An unfavourable effect was also produced on our national literature, and on the progress of the press, by the licentiousness introduced by the literary parasites and courtesans of the Restoration. Under such a state of mental depression, Milton could obtain only 15*l.* for the MS. of his immortal *Paradise Lost*, and an Act of Parliament was actually in force enacting that only twenty printers should practise their art in the whole kingdom! Burton, who lived near this time, has drawn a miserable picture

of the abject condition of literary men when they had such patrons to rely upon: 'Rhetoric only serves them to curse their bad fortunes; and many of them, for want of means, are driven to hard shifts. From grasshoppers they turn humble-bees and wasps, plain parasites, and make the Muses mules, to satisfy their hunger-starved paunches and get a meal's meat.'

In addition to these impediments, the crown endeavoured, in the reign of Charles II., to destroy the activity of the press; 'and in this it had the example not only of all former reigns (in which nothing had been legally published without a license), but of the Long Parliament itself, which had laid severe restrictions upon the printing of "scandalous and unlicensed papers." At one time, indeed, it was ordered that no printing should be carried on anywhere but in the city of London, and the two universities; and all London printers were to enter into a bond of 300*l.* not to print anything against the government, or without the name of the author (or at least of the licenser) on the title-page, in addition to their own.' (Eccleston's *English Antiquities*, p. 325.) Speaking of the consequent scarcity of books in country places in the year 1685, Lord Macaulay (*History of England*) says:—

'Literature which could be carried by the post bag then formed the greater part of the intellectual nutriment ruminated by the country divines and country justices. The difficulty and expense of conveying large packets from place to place was so great, that an extensive work was longer in making its way from Paternoster Row to Devonshire or Lancashire than it now is in reaching Kentucky. How scantily a rural parsonage was then furnished, even with books the most necessary to a theologian, has already been remarked. The houses of the gentry were not more plentifully supplied. Few knights of the shire had libraries so good as may now perpetually be found in a servants' hall, or in the back parlour of a small shopkeeper. An esquire passed among his neighbours for a great scholar, if *Hudibras* and *Baker's Chronicle*, *Tarlton's Jests* and the *Seven Champions of Christendom*, lay in his hall window among the fishing rods and fowling pieces. No circulating library, no book society, then existed even in the capital; but in the capital those students who could not afford to purchase largely had a resource. The shops of the great booksellers, near Saint Paul's Churchyard, were crowded every day and all day long with readers; and a known customer was often permitted to carry a volume home. In the country there was no such accommodation; and every man was under the necessity of buying whatever he wished to read.' And he adds in a note that 'Cotton seems, from his *Angler*, to have found room for his whole library in his hall window; and Cotton was a man of letters. Even when Franklin first visited London in 1724, circulating libraries were unknown there. The crowd at the booksellers' shops in Little Britain is mentioned by Roger North in his life of his brother John.'

It has been ascertained by counting that the whole number of books printed during the fourteen years from 1666 to 1680, was 3,550, of which 947 were divinity, 420 law, and 153 physic, so that two-fifths of the whole were professional books; 397 were school-books, and 253 on subjects of geography and navigation, including maps. Taking the average of these fourteen years, the total number of works produced yearly was 253; but deducting the reprints, pamphlets, single sermons, and maps, we may fairly assume that the yearly average of new books was much under 100. Of the number of copies constituting an edition we have no record; we apprehend it must have been small, for the price of a book, so far as we can ascertain it, was considerable.

The period from the accession of George III. to the close of the eighteenth century is marked by the rapid increase of the demand for popular literature, rather than by any prominent features of originality in literary production. Periodical literature spread on every side; newspapers, magazines, reviews, were multiplied; and the old system of selling books by hawkers was extended to the rural districts and small provincial towns. Of those thus produced, the quality, with a few exceptions, was indifferent, and their cost was considerable. The principle, however, was then first developed, of extending the market, by coming into it at regular intervals with fractions of a book, so that the humblest customer might lay by each week in a savings-bank of knowledge. This was an important step, which has produced great effects, but which is even now capable of a much more universal application than it has ever yet received. Smollett's *History of England* was one of the most successful number-books; it sold to the extent of 20,000 copies.

We may exhibit the rapid growth of the publication of new books, by examining the catalogues of the latter part of the eighteenth century, passing over the earlier years of the reign of George III. In the *Modern Catalogue of Books*, from 1792 to the end of 1802, eleven years, we find that 4,096 new works were published, exclusive of reprints not altered in price, and also exclusive of pamphlets. Deducting one-fifth for reprints, we have an average of 372 new books per year. This is a prodigious stride beyond the average of 93 per year of the previous period. But we are not sure that our literature was in a more healthy condition. From some cause or other, the selling price of books had increased, in most cases 50 per cent., in others 100 per cent. The 2*s.* 6*d.* duodecimo had become 4*s.*; the 6*s.* octavo, 10*s.* 6*d.*; and the 12*s.* quarto, 1*l.* 1*s.* It would appear from this that the exclusive market was principally sought for new books; that the publishers of novelties did not rely

upon the increasing number of readers; and that the periodical works constituted the principal supply of the many. The aggregate increase of the commerce in books must, however, have become enormous, when compared with the previous fifty years; and the effect was highly beneficial to the literary character. The age of patronage was gone. (*Penny Magazine.*)

According to the last census, upwards of 30,000 persons are employed in printing, and 12,000 in bookbinding.

Printing in Scotland.—Printing was introduced into Scotland, and begun in Edinburgh, about thirty years after Caxton had brought it into England. Mr. Watson, in his *History of Printing*, says that the art was introduced into Scotland from the Low Countries by the priests who fled thither from the persecutions at home. Be this as it may, we find James IV. granting a patent in 1507 to Walter Chapman, a merchant of Edinburgh, and Andrew Mollar, a workman, to establish a press in that city. According to bibliographers, the most ancient specimen of printing in Scotland extant is a collection, entitled the *Porteus of Noblenes*, Edinburgh. In 1509, a *Breviary of the Church of Aberdeen* was printed at Edinburgh; and a second part in the following year. Very few works, however, appear to have issued from the Scottish press for the next thirty years; but from 1541, the date from which we find James V. granting licenses to print, the art has been pursued with success in the metropolis. At present, and from the beginning of the present century, it is perhaps the most distinguished craft in the city, being conducted in all its departments of typefounding, printing, publishing, and, we may add, paper-making at the mills in the vicinity.

Ireland.—Printing was not known in Ireland till about the year 1551, when a book in black letter was issued from a press in Dublin; but till the year 1700, very little printing was executed in that country, and until very recently Ireland had acquired little celebrity in this department of the arts, although possessing some respectable printing establishments.

America.—The art of printing has readily taken root and flourished among the civilised inhabitants of North America. The first printing press established in the American colonies was one set up at Cambridge, in Massachusetts, in the year 1638, the era of the foundation of Harvard College. It was established by the exertions and joint contributions of different individuals in Europe and America; and there is no doubt that the mechanism and types were imported from England. The first work which issued from this press was the *Freeman's Call*, and the second the *Almanac for New England*, both in 1639; the first book printed was the New England version of the Psalms, an octavo volume of 300 pages. In 1676, books began to be printed at Boston; in 1686, the art became known in Philadelphia; and in 1693, in New York. In the year 1700 there were only four printing presses in the colonies. Since that period, and especially since the revolution, which removed everything like a censorship of the press, the practice of the art has undergone enormous expansion. Among the occupations enumerated in the census of 1850 were 14,740 printers, and 3,414 bookbinders. In their style of typography and bookmaking, the Americans are still inferior to the English, sacrificing beauty and durability to economy and despatch. (*Chambers's Inform.*)

France.—The activity of the French press has very greatly increased since the time of the first Napoleon. Count Daru, in 1827 (*Notions Statistiques sur la Librairie*), estimated the number of printed sheets (exclusive of newspapers) produced by the French press in 1816, at 66,852,883; and it appears that in 1836 the number of printed sheets (exclusive of newspapers) had increased to 118,857,000; so that it may now be fairly estimated at from 130,000,000 to 140,000,000 sheets. The quality of many of the works which have issued from the French press is also very superior, such as the *Biographie Universelle*, the *Art de vérifier les Dates*, and Bayle's *Dictionary*; and it is doubted whether such books could have been published in any other country.

Germany.—The German printing press is always in a state of the greatest activity; the trade in books being very much facilitated by the book fairs of Leipsic, the Easter fair especially being frequented by all the booksellers of Germany, besides those of France, Switzerland, Denmark, Livonia, &c., in order to settle their mutual concerns and form new connections. In 1814 began a literary deluge, which still continues to increase. For the 5,000 works which then sufficed for the annual demand, we have now from 6,000 to 8,000. Private libraries are diminishing, and the public ones are daily increasing.

In Austria the printing press has made rapid strides of late years. The Imperial printing office in Vienna, under the able management of M. Auer, has become an establishment of the highest interest. At the Exhibition of 1851, he presented to the notice of the public a collection of the Lord's Prayer, printed with Roman type in 608 languages and dialects, the second section of which contained 206 languages and dialects, printed in the characters proper to the languages of their respective nations. He has collected together the following founts, many of which are, however, to be found in the British type foundries:—

Hieroglyphic.	Palmyric.
Hieratic.	Estrangelo.
Demotic.	Syriac.
Ethiopic and Amharic.	Cufic.
Himyaritic.	Arabic, Neschi.
Himyaritic (ornamented).	Mauritanic.
Cabylic, American inscript. Touaric and Thugga.	Phenician (ornamented).
	Punic.
Ancient Hebrew.	Numidian.
Samaritan.	Etrurian.
Hebrew.	Ancient Italian.
Raschi, or Rabbinic.	Runic.
German Hebrew.	Gothic.
German Raschi.	Celtic.
Hebrew, Spanish, Levantine.	Celtic (new shape).
Aramaic.	Anglo-Saxon.
Chaldee.	Ancient Greek.

Greek.
Coptic.
Cyrillic.
Cyrillic (differently shaped).
Russian, Servian, Wallachian.
Glagolitic.
Albanian.
Albanian (differently shaped).
Lycian.
Armenian.
Georgian.
Georgian (ecclesiast. letters).
Persepolitan cuneiform letters.
Pehlvi.
Zend.
Cabul.
Peguan.
Older Ind. signs.
Western Grotto inscription.
Asoka inscription.
Inscription of Guzerat.
Dynasty of Gupta (Allahabad).
Bengali.
Ahom.
Tibetan.
Passepa.
Kutila (ten years after Christ).

Tschirokisian.

Russia.—The art was not introduced into Russia till the year 1560, when it was made known by a Russian merchant, who conveyed thither the materials of a printing office, with which many neat editions were printed. But as the Russians are a very superstitious nation and apt to raise scruples without any foundation, some of them, apprehending that printing might make some confusion or change in their religion, hired men to destroy the types and presses. No attempt was made to repair this injury or to discover the perpetrators of the fact. However, since that time they have admitted the press into Moscow and St. Petersburg, where until recently it made but slow progress.

Peculiarities of Early Printed Books.—The following are the points peculiar to the earliest productions of the first printers:—

Their forms were generally either large or small folio, or at least quarto: the lesser sizes were not in use.

The leaves were without running title, direction-word, number of pages, or divisions into paragraphs.

The character itself was a rude old Gothic mixed with secretary, designed on purpose to imitate the hand-writing of those times; the words were printed so close to one another, that it was difficult and tedious to be read, even by those who were used to manuscripts, and to this method; and often led the inattentive reader into mistakes.

Their orthography was various and often arbitrary, disregarding method.

They had very frequent abbreviations, which in time grew so numerous and difficult to be understood, that it became necessary to write a book to teach the mode of reading them.

Their periods were distinguished by no other points than the double or single one, that is, the colon and full-point; but a little after, they introduced an oblique stroke, thus, /, which answered the purpose of our comma.

They used no capital letters to begin a sentence, or for proper names of men or places. They left blank spaces for titles, and initial letters or other ornaments, in order to have them supplied by the illuminators, whose art, though in vogue before and at that time, did not long survive the improvements made by the printers in this branch of their art. [ILLUMINATION, ART OF.] These ornaments were exquisitely fine, and curiously variegated with the most beautiful colours, and even with gold and silver; the margins likewise were frequently charged with every variety of figures of saints, birds, beasts, monsters, flowers, &c., which had sometimes a relation to the contents of the page, though often none at all. These embellishments were costly; but for those who could not afford a great price, there were inferior ornaments, which could be done at a much cheaper rate.

The name of the printer, his place of residence, &c. &c., were either wholly omitted, or put at the end of the book, not without some pious ejaculation or doxology.

The date was likewise omitted or involved in some cramped circumstantial period, or else printed either at full length, or by numerical letters, and sometimes partly one way and partly the other; thus, One Thousand CCCC and lxxiiii. &c., but always at the end of the book.

There was no variety of characters, no intermixture of Roman and Italic, these being of later invention; but their pages were continued in a Gothic letter of the same size throughout.

They printed but few copies at once, for 200 or 300 was then esteemed a large impression; but upon encouragement from the learned, they increased their numbers in proportion.

Types.—Although most of the early printers were type-founders themselves, it does not appear in any prologue or colophon to the books printed by Caxton that he lays claim to the title of type-founder. It would appear that he obtained his type, which is precisely of the same character as that of John Brito of Bruges, from that city, or from the same founders who supplied or manufactured it for John Valdener of Utrecht. But as the art extended, the workmanship became inferior; so that while the productions of the first printers were executed in a very superior style, and the embellishments showed a great proficiency both in design and engraving, the productions of their competitors had all the crudeness and imperfection of a new invention; and in the seventeenth century the art sank into a very low state. At the commencement of the eighteenth century, Caslon made great improvements in casting types; as also Baskerville of Birmingham, in 1750, both in types and printing, which were subsequently carried to great perfection by Besley, Bulmer, Clowes, Corrall, Davison, McCreery, Spottiswoode, Whittingham, and a few others in London; by the Foulis, in Glasgow; by the Ballantynes, in Edinburgh; by Bodoni at Parma; by Didot in Paris; and by Brockhaus in Leipsic.

Practice of Printing.—Two classes of workmen are generally employed in printing: viz. *compositors*, who *set up* the types into lines and pages according to the MS. or *copy* furnished by the author; and *pressmen*, who apply ink to the surface of the *form* of types, and take off the impressions upon paper. The pressmen who work steam presses are called *machine minders*.

The following is the mode of proceeding adopted in most of the extensive establishments in London: The first thing done, when the sizes of page, type, and paper, are determined on, is to look over the MS., and see that it is correctly paged. It is then handed to a *clicker*, or foreman of a *companionship*, or certain number of compositors, each of whom has a *taking of copy*, or convenient portion of MS., given to him, to be set up in type.

Printers' types are of great variety in size, amounting to forty or fifty; the smallest is called *brilliant*, but is seldom used; *diamond* is a size larger, and *pearl* larger still, which latter type is used for printing the smallest Bibles and Prayer Books.

The larger sizes, used for printing bills posted in the streets, are usually called *double pica, two-line pica, two-line English, five-line pica, ten-line pica*, and so on. A complete assortment of printing types of one size is called a *fount*, and the fount may be regulated to any weight. Type-founders have a scale, or *bill*, as it is called, of the proportional quantity of each letter required for a fount, the letter *e* being more frequently used than other letters. A full account of printers' types is given under the heading Type.

Each compositor works at a kind of desk, called a *frame*, and generally has a frame to himself. The frames project laterally from the wall, with a left-hand light. Each frame is constructed to hold two pairs of cases, upper and lower, at the top. The types are arranged,

Upper.

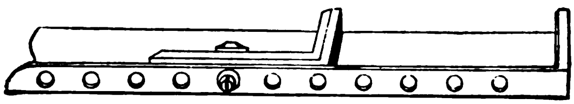
each sort by itself, in little cells or *boxes*. The upper case, having ninety-eight boxes, all of equal size, contains the capital and small capital letters, figures, accents, and other types not used so frequently as the smaller letters; and in the lower case, which has fifty-four boxes of four different sizes, are disposed the small letters, together with the points, spaces, quadrats,

&c. The boxes in the cases are arranged in the best possible manner for facilitating the work of the compositor, and enabling him to pick up the types rapidly, the letters most frequently used being placed nearest to his hand; thus the point to which he brings the letters, after picking them out of their cells, is not far removed from the centre of the lower case; so that in a range of about six inches on every side he can obtain the c, d, e, i, s, m, n, h, o, p, u, t, a, and r. The *spaces* required for the division between every word lie close to his hand, at the bottom of the central division of the lower case. The cases, particularly the upper case, are placed in a sloping position, that the compositor may the more readily reach the upper boxes. The diagrams on p. 74 exhibit a pair of cases arranged according to the modern method.

The compositor stands opposite to his cases; and, having received directions respecting the size of the type, the width of the page, the author's wishes as to punctuation, capitals, italics, &c., places his copy before him, on a spare part of the upper case, and holds in his left hand a small instrument called a *composing stick*, usually made of iron, with a movable slide, capable, by means of a screw, of being adjusted to the different widths required in miscellaneous printing, as seen in the illustration. Having adjusted his stick to the proper width or *measure*, he lays in it a *setting rule*, or smooth piece of brass, the width of the measure, and the height of the type. With



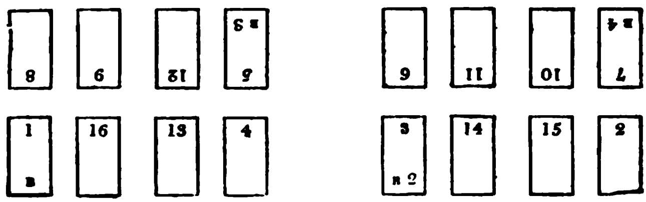
the right hand he now picks up the types, and arranges, or *sets*, them one by one in his composing stick. He does not look at the face of each, but only glances at the *nick* (see cut in art. TYPE), and takes for granted that if it come from the right box it must be the right letter. He secures each letter with the thumb of the left hand, as the types are placed side by side in line from left to right; and, when he comes to the end of his line, and finds that he has a syllable or word which will not fill out the measure, he has to perform a task which requires considerable care and taste. This is called *justification*. The first and last letters must be at the extremities of the line; and there must not be wide spaces between some words and crowding in others, but the distances between them must be made as nearly as possible uniform by changing the *spaces* (or short blank types, not so high as the letters, and therefore giving no impression), and thus *getting in* or *driving out* part or the whole of a word. The first line being thus justified, the compositor proceeds with the setting up of the next, and so on with a sufficient number of lines to fill his stick, and then, clasping the *stickful* by the rule and between the thumbs and first and second fingers of both hands, lifts the mass of types out of the stick, and places it upon a *galley*, or oblong tray of wood or metal, having an edge at the left side and top half an inch in height. This operation of filling and emptying the stick is repeated till the galley is sufficiently full, or the taking of copy is finished; when the *matter*, as it is then called, is taken away by the clicker, who divides it into the required lengths of pages, placing head-lines, signatures, &c., and binding them round tightly with cord. The clicker then *lays down* the pages in their proper positions on the *imposing stone*—a flat, smooth slab of stone, or, better, of iron—and they are fastened together in a *chase*. This operation is called *imposing*. The chase is a rectangular frame of different dimensions, according to the size of the paper to be printed, having two cross-pieces of the same metal, called a long and short cross, formerly mortised at each end, so as to be taken out occasionally, but now fixed. By the different situations of these crosses, the chase is fitted for different volumes: for quartos and octavos one traverses the middle lengthwise, the other broadwise, so as to intersect each other in the centre; for twelves and twenty-fours the short cross is placed nearer one end of the chase than the other; for folios, the short cross only is required, and for broadsides and small jobs no cross is wanted.

For fixing the pages in their places, the form is *dressed* thus: a set of *furniture*, consisting of slips of wood or metal, about half an inch in height, and of various thicknesses, is placed, some at the head, called *head-sticks*, some between the pages, called *gutters*, and others at the sides and feet, called *side* and *foot sticks*. The side and foot sticks are larger at one end than at the other, so that small wedges of wood, or *quoins*, may be driven tightly between them and the sides of the chase, locking up the types so firmly that the *form*, as the mass is then called, and which is represented in the cut (which by the way has no cross to the chase), may be carried from place to place with perfect safety. A form of eight pages of this Dictionary contains between 40,000 and 50,000 separate letters and spaces.

The sizes of books are reckoned by the number of leaves into which a sheet of paper is folded. Thus the largest size is *broadside*, or the whole size of the sheet; *folio*, or half the sheet; *quarto*, or a sheet folded into four leaves; *octavo*, or the sheet folded into eight leaves; *duodecimo*, or the sheet folded into twelve leaves; and so on. In imposing, the pages are of course laid down in positions the reverse of those which they will take when printed. The following diagrams show the mode of imposing sheets of 8vo and 12mo, the *outer form* being the outside, and the *inner form* the inside of the sheet.

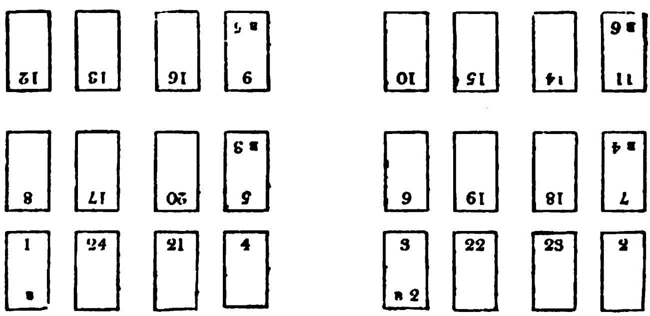
SHEET OF OCTAVO.

Outer Form. *Inner Form.*



SHEET OF TWELVES.

Outer Form. *Inner Form.*



It is necessary that the distances between the pages in each form should be placed with such exactness that the impression of the pages in one form shall fall exactly on the back of the pages of the other; thus making what is termed *register*.

As it is next to impossible but that mistakes should occur in *setting up* the types, the form is carried to a *proof press*, and an impression is taken, called the *first proof*. This proof, with the MS., is handed to the corrector of the press, or *reader*, and a *reading boy* reads the copy to him while he examines the proof and marks the necessary corrections and errors of the compositor. In correcting a proof sheet a set of symbols are used for the purpose of calling the attention of the compositor to the several kinds of errors, and to direct him how they are to be amended. These marks are best shown by the specimen of a corrected proof given under the head CORRECTING. When the corrector, or *reader*, has read his proof, it is handed to the compositor, who unlocks the form, and makes the corrections in the types, by lifting out the wrong letters by means of a sharp awl, or *bodkin*, and putting in right ones in their places. The form is then locked up again, taken to the press, and another proof is *pulled*. This is termed *the revise*, and is sent to the reader, with his first proof, that he may see that all the corrections have been properly made, put queries against doubtful matters for the author's consideration, and send it, thenceforth called a *clean proof*, with the MS., to the author. When the author returns his proof and revise, and is satisfied that the sheet is correct, the form, after having been finally read with care for press, is taken to the press or machine to have the requisite number of impressions struck off. Before this is done, however, care is taken that the matter at the beginning of the sheet connects with that at the end of the preceding, that the pages are correct, and that the *signatures* are in order.

The signatures are generally small capital

letters placed at the foot of the first page of each sheet, commencing with B, and omitting the J, V, and W. They are said to have been first used by John Koelhof, at Cologne, in 1472; but they exist in an edition of *Terence*, printed by Antonio Zorat, at Milan, in 1470. There is a Venetian edition of 'Baldi Lectura super Codic.' &c., printed by John de Colonia and Jo. Manthen de Gherretzem, in 1474, in which it is evident that these printers had only just become acquainted with the use of signatures, as these marks were not introduced till one-half of the work had been printed. The following tables show the signatures and folios of any given number of sheets, up to twenty-two in 8vo and 12mo, and up to eight in 18mo:—

Sheet of Octavo			Sheet of Twelves			Sheet of Eighteens

The paper used in printing is always damped before being sent to the press, wet paper taking the ink considerably better than dry. The warehouseman delivers the proper quantity of paper to the wetter, which is generally wetted thus: The quire of paper is opened, the fold at the back broken, and the paper divided into three, four, or five portions, or *dips*, drawn through a trough of clean water and laid on a board, dip after dip, till a convenient heap is made. This is put into a screw-press, a little pressure applied, and the next day the whole is *turned* and slightly pressed again, so that fresh surfaces of the paper coming into contact, the moisture is equally diffused throughout the heap. The paper used in printing is of three kinds: *imperfect paper*, consisting of 20 quires of 24 sheets, or 480 sheets to the ream; *perfect paper* (that most generally used) consisting of 21½ quires, or 516 sheets; and *news paper*, consisting of 20 quires of 25 sheets each to the ream, or 500 sheets. The *stamped sheets* of news paper (generally called *stamps*, and the plain paper *blanks*) are always received and delivered by the net number without allowing for spoilage in the press work; but in book work it is the practice to allow 16 sheets in each ream for *tympan sheet* and spoiled sheets. This number of sheets is, however, not all spoilt; the difference between the bad and the extra 16 sheets being delivered to the publisher as *overplus*. The table on the next page shows the quantity of perfect and imperfect paper required for one sheet of 16 pages of a work like this Dictionary, from 12 to 10,000 copies.

When the sheet is printed off by the pressman (as described below), the compositor lays up the forms, distributes the type, and proceeds, sheet after sheet, till the body of the work is finished; then the title, dedication, preface, introduction, contents, and any other matter left to the end is proceeded with, these being usually printed last. The distribution of the types, or putting back the letters into the several compartments of the case to which they belong, is performed with the greatest rapidity. The compositor wets the whole page or form, and takes up a number of lines on his composing rule. This wetting causes the types to adhere slightly together, and renders the

manipulation easy. He then takes up a few words between his right-hand finger and thumb, and by a dexterous motion throws off the several letters into their various boxes. Distribution is performed about four times faster than composition.

Presswork.—The pressman's business is to *work off* the forms thus prepared and corrected by the compositor; in doing which there are four things required: paper (prepared as above described), ink or colouring matter, balls or rollers, and a press or machine. [Paper; Printing Ink; Press; Printing Balls or Rollers; Printing Machine.]

In working at a hand press, the pressman first lays the *inner form* on the press, and prints one copy, which is called a *press revise*; this he takes to the person appointed to revise it, and while that is being done proceeds to secure the form on the table of the press by means of quoins; to place his *tympan* sheet; to fix the *points*, which make small holes in the paper, enabling him to cause the pages to fall precisely on the back of each other when the second side of the paper is printed, and to produce an even and uniform impression in all the pages. He then cuts his *frisket*, which preserves the margin of the paper clean, and, when the revise is corrected, proceeds to ink the surface of the types by means of balls or (most frequently) rollers. When the whole impression of one side of the paper is printed, he lifts the form off the press, washes the ink off the face of the type with lye, and rinses it with water. He then proceeds in a similar manner with the *outer form*, which completes the sheet. This process is continued sheet after sheet till the work is complete, care being taken that the work is printed of the proper colour, and that that colour should be uniform throughout the book.

Warehouse Work.—When the sheets have been printed on both sides, the warehouseman takes them away, and hangs them up on poles to dry, varying the number of sheets hung up together from five or six to ten or eleven, according to the heat of the room, or the pressure of business. When dry the sheets are taken down from the poles, carefully *knocked up*, and put away in the warehouse in piles. The sheets are then *cold-pressed*. The pressure is applied by means of hydraulic

pumps, of from two to five hundred tons pressure. They consist simply of double-acting force-pumps, with rams or cylinders of small bore, but with a great force from an engine to act upon the pistons. This forces the water through a very strong pipe beneath the floor to other large cylinders, fitted also with pistons, under the presses. Of course, whatever force is applied to the small pistons in the pumps, an equal amount of pressure is produced on every square inch of the large pistons in the cylinders under the presses, and thus a prodigious pressure on the sheets of paper is the result.

Above the upper part of one of these large cylinders are square iron plates, which form a base on which to rest the piles of sheets of paper to be pressed. These plates, like those of similar function in the printing-press, are very thick and are stiffened beneath by iron braces. Each press may be connected with the pump, or disconnected from it at pleasure, so that one may be giving up or receiving a supply of sheets while the others are full and in action.

Each sheet, before it is put into the press, is placed between two sheets of thin smooth millboard. The process of *filling in* the sheets between the millboards is performed at very wide tables. It requires two boys at each table to do each work. One takes out from between two sheets of pasteboard the sheet of paper that has been pressed, and the other, almost at the same instant, puts another in, shifting the several sheets, both of paper and pasteboard, from pile to pile, in the course of the manipulation, with dexterity and rapidity. As fast as a sufficient number of the rearranged sheets are ready, a boy takes them away, and places them in the press, while another boy continually brings a fresh supply of those that have been pressed to take their places. The pressing which the sheets receive in this operation makes an astonishing difference in the smoothness and beauty of the paper when the book comes to be bound.

When the book is nearly finished, from ten to fourteen consecutive sheets are laid upon the gathering board in order, and collected sheet by sheet by boys, who deposit each *gathering* in a heap at the end of the table, so constructed that when a boy has deposited his gathering he has only to turn himself and begin again. These gatherings are then carefully *collated*, to ascertain that the different sheets are correct and in order, and folded up the middle. When the work is finished the gatherings are put together, or *in books*, one of each forming a copy of the work, and pressed. The work is now completed, and awaits the order of the bookseller, &c., for delivering the copies into the hands of the bookbinder.

Printing in Colours.—In many of the early printed books, the initial letters, and occasionally other parts, were printed in red. This was done by two workings at press, and was an imitation of the earlier fashion of illuminating MSS. This is the case with the Mentz Bible by Fust and Gutenberg. The first printers soon began to print these large ornamented letters, the letter itself being in some instances red and the ornamental part blue, in others the letter is blue and the ornamental part red. These letters were afterwards finished by hand, as is apparent in the *Psalter* of 1457, printed by Fust and Schœffer, who also showed great ingenuity and skill in the large letter B in the same book, which is printed with red ink, and the ornamental part, consisting of a flourished line, as if it had been drawn with a pen, extending from the top to the bottom of the folio page, with blue ink. Of two copies which we have examined, one was in the library of George III. at Buckingham Palace, and the other is in the possession of Earl Spencer.

The first edition of the *Speculum Humanæ Salvationis*, which was printed at Haarlem, about the year 1440, by Laurence Coster, has engravings on wood printed in a different coloured ink from the body of the work. A copy of this rare and curious work, which Mr. Savage examined some years ago, in the valuable collection of Messrs. Longman, impressed him momentarily with the idea that the engravings were pen-and-ink drawings, and that the ink had turned brown with age, so precisely was this effect produced by the tone of the ink.

We mention these early specimens of printing with coloured inks, and in the case of the *Psalter* having two blocks of wood with two different colours, as being produced by means of the press, coeval with the generally received date of the invention of printing, to show the impossibility of the case. For, looking at the freedom of the engraving in the letter B, and the skill of the workman in printing it, it must be evident to every person conversant with the art that this perfection could only be obtained by long practice; and the contrast between these productions of the first practitioners and their competitors, when the art became public, puts the question beyond a doubt, as an examination of the facsimiles given by Heinecken from *Fables* printed at Bamberg about 1461, from the *Legendes* printed at the same place about 1470, and also the *Fables of Æsop* by Caxton, will, we think, satisfy the most scrupulous and sceptical.

Towards the end of the fifteenth century the art was extended to the imitation of pen-and-ink sketches with a coloured ground, by the great masters of painting; and in a few years it was further extended to the imitation of drawings in chiaroscuro, and that with such success as to induce some of the first artists to encourage it by drawing the subjects on the blocks. The first practisers of this extension of the art were, Michael Wohlgemuth of Nuremberg, who furnished the designs for the *Nuremberg Chronicle*, and also engraved them on wood, and Mair, a native of Landshut, the disciple of Martin Schön; between whom the priority rests of printing in chiaroscuro. After them were Girolamo Mocetto, Lucas Cranach, Baldassar Peruzzi, Hans Burghmair, and Ugo di Carpi (who has been generally

regarded as the inventor of this style of printing, but dates prove this opinion to be erroneous), Domenico Beccafumi, John Ulric, Albert Altdorfer, Hans Baldung, Lucas van Leyden: all these were born in the fifteenth century. In the sixteenth century, there were Antonio da Trenta, Giovanni Nicolo Vicentino (called Rossigliani), Herbert Goltz or Goltzius, Andrew Andreani, Henry Goltz or Goltzius, Abraham Bloemaert, Paul Moreelze, Bartolomeo Coriolano, Giovanni Battista Coriolano, Christopher Jegher, George l'Allemand, and Frederick Bloemaert. In the seventeenth century, there were Louis Businck, Vincent le Sueur, Antonio Maria Zanetti, Nicholas le Sueur, Comte de Caylus, Edward Kirkhall, and John Baptist Michael Papillon. This last-mentioned engraver, in his treatise on *Engraving on Wood*, expressly states that Albert Durer engraved some subjects in chiaroscuro, and that he had examined them in the collection of the king of France; Parmigiano also superintended the printing in this manner of a number of his own designs; Titian, Raffaelle, and other eminent masters made designs on the blocks for printing; and the author of *An Enquiry into the Origin of Printing in Europe* states, that 'one of the greatest princes and connoisseurs of our age used to say, he saw nothing in prints that could give him the pleasure he received from looking at the wood prints done in chiaro-oscuro by Hugo di Carpi.' This prince was the duke of Orleans, regent of France.

After these were John Baptist Jackson, who executed a number of subjects, of a large size, in chiaroscuro, copied from celebrated paintings in churches in Italy, and from private collections; he afterwards established a manufactory at Chelsea for printing paper-hangings in oil colours, a speculation, however, which was unsuccessful. Some of his productions printed in colours were complete failures, the oil having spread in the paper; and the subjects being in the first instance engraved with strong lines, they have the appearance of coarse engravings coloured by children. Jackson flourished from 1720 to 1754. Mr. John Skippe, an amateur, executed many subjects in chiaroscuro very adroitly.

Gubitz, an engraver at Berlin, has produced a great number of subjects printed in colours, of a very superior character, but none of them can be called imitations of drawings. Mr. Savage was the first who attempted to imitate drawings in water colours by means of the common printing press, and accomplished the applying of all the colours used by artists to the composition of printing ink, thus serving as a pioneer to more skilful persons who might devote themselves to this branch of art; and he succeeded in producing fac-similes of the drawings of different artists so as to deceive everyone who examined them. Messrs. Whiting and Branston, of Beaufort House, applied printing in coloured inks to the prevention of forgery, and to embossing on paper; and Messrs. Vizetelly and Branston have produced some very tasteful things in colours; but neither of these establishments, to our knowledge, turned their attention to the imitation of drawings. Mr. Baxter subsequently executed beautiful specimens in a manner that would have been deemed totally impossible in the early state of the art.

The practice of printing parts of books in red ink is still followed in some prayer-books and almanacs, the saints' days and holidays being *red-letter days*. Some years ago a curious book was written and published on printing in colours by Mr. Savage. Still more recently, printing in gold and other metals has been practised. This is done by printing with a sort of size, and afterwards applying the metal leaf. But the copies of some of the works of the great painters, considered as specimens of printing in colours, are really beautiful as works of art. The copy picture is made in colours, and the blocks for printing each colour and shade are cut in relief on *surface-metal*, consisting of perfectly smooth plates of type metal. These plates are then printed by the ordinary method, great care, however, being taken that each colour falls in its right place.

Several ingenious contrivances have been invented for working in various colours, such as Dolby's, Loft and Stafford's, Carpenter's machines, &c. It will be sufficient to describe the last, as given in Wood's *Typographical Advertiser*:—

'The invention patented some time ago by Mr. C. Knight, is a process whereby fac-similes of designs in four colours are produced on the same sheet, before it leaves the press, by means of a *revolving carriage* or bed upon which the blocks are secured. The process, invented a few years ago, for printing in four colours by means of *turning the tympan* with the sheet secured on it, was somewhat less complicated than Mr. Knight's. These methods, however, necessitate the application of the four coloured inks at every revolution and impression; and also involve considerable outlay for machinery. W. Carpenter's process, on the contrary, gives rise to no expenditure whatever; and, in its manipulation, everything is carried on in as straightforward a manner as ordinary black printing. It may be thus briefly described: A form, for example, is set-up by the compositor; he then divides it into four sections, and so imposes them, in one chase, that the same relative corner of each (whichever may be chosen) shall point towards the middle of the chase. It is then ready for the pressman. It requires making-ready, with points placed, according to the tact of the workman, in such position as may be deemed expedient; four points being sufficient in all, and these so placed that the sheet may be pointed when turned either to the right or to the left hand. Should a thousand copies be required, the two hundred and fifty sheets are printed in the first colour. They are then simply turned round, in either direction, and again printed with the second colour. They are then again turned round,

and printed with the third colour, and again for the fourth. And now we have a thousand perfected impressions, consisting of four varieties—that is, with the four colours differently arranged: two hundred and fifty of each kind. Should the whole possible number of combinations of four colours—namely, twenty-four—be required, nothing more is necessary than, while the sheets are being worked in the second colour, to turn a portion of their number into the third and fourth positions—which produces three kinds of sheets, or twelve single varieties—and, while working the third colour, take half of each of the three kinds, and work them respectively in the second, third, and fourth positions—producing six kinds of sheets, or twenty-four single varieties. It will be readily seen that, in the production of four varieties only, a different arrangement of them will be produced according to the direction in which the sheets are turned, and likewise the order in which the several colours are employed. It will also be seen, by practical men, that the blocks and the tympan retaining their relative positions throughout, the inner-lays are not interfered with, as they would be if a revolution took place in either case. Moreover, one inking apparatus is sufficient; and each colour has time to set before another is worked over it—which may sometimes be required.'

The following is the mode of printing cuts with two or more *rainbow tints* at the same time: Take the cut, which is to be printed in black, ink it well and rather full, and get a perfect impression on paper not very damp; then lay the face of the printed paper carefully on the surface of the block prepared for engraving the whites on the tinted ground, and give it a good soft pull. This will transfer to the tint block a fac-simile of the wood engraving itself. The tint-block is then handed over to the engraver, who cuts out the whites for the high lights, &c., according to his taste, and with a view to effect. The tint-block is printed first, and the pressman must be careful in distributing his different inks to make them fade away and blend at the given points. This is an easy matter after a little practice. The black block is then worked over the tint in the usual way.

Composing and Distributing Machines.—The desire to expedite the process of composing and distributing has led to the invention of some ingenious machines for those purposes. One, the work of M. Sörensen, of Copenhagen, was exhibited at Paris in 1855, and was described by Mr. Charles Knight in his report. Three others, the inventions of Mr. Young, of Fleet Street, London, and of Mr. Alden and Mr. Mitchell, both of New York, were shown at the Great Exhibition in London in 1862. We can only afford room for a short account of the latter, as described by the inventor himself. Two of each of his composing and distributing machines have been for some years at work in the establishment where this Dictionary is printed. The *compositor* (says Mr. Mitchell) is in shape a right-angled triangle, placed horizontally, with a key-board at one of the sides, furnished with thirty-nine keys. Each key, when pressed, strikes out a type, from one of an equal number of brass slides standing at an incline upon the machine in a row nearly parallel to the key-board. The type thus liberated is conveyed upon a band, moving in a direction at right angles with the key-board, to another band (forming the hypothenuse of the triangle), which carries it on to its destination. Arrived here, it is placed on end and pushed forward, to make room for the next type, by means of a notched or serrated wheel called the *setting wheel.* The words are thus put together with great rapidity, in a long line of about thirty inches, which is afterwards divided by the compositor into lines of the required length. The principle of the machine consists in the combination of bands of lengths and velocities of revolution so varied as to enable the types at different distances from the wheel to reach it in the order in which the keys are struck. The *compositor* is capable of setting up types at the rate of six letters per second, or 21,600 per hour; but as the human fingers cannot attain to such rapidity, and allowance must be made for the operations of *justifying* and *correcting*, the work of an average trained operator will probably not exceed 24,000 or 25,000 ens per day, which is about equal to the work of two men setting up type in the ordinary mode. As each machine can employ two operators, the daily production is about 50,000 ens.

The *distributor* is a small machine of circular form. The lines of type to be distributed are placed successively in a long channel, in which they are pressed forward towards a vibrating metal *finger*. By this finger each type is separated from the line, pushed aside, and dropped on to a grooved brass wheel revolving horizontally. In the grooves of this wheel pins are placed, on which the types are hung by means of nicks, the ends of the types projecting below the under surface of the wheel at distances varying according to the position of the nicks. As each letter arrives over its receptacle, it is lifted off its pin, and dropped into its place, being pushed a little forward to make way for the next arrival. When the line is filled in this way, it is removed by the boy to the *compositor*.

The distributor is self-acting, and requires only the attention of a boy. It distributes 8,000 letters per hour.

Printing for Special Purposes.—The art-printing called NATURE PRINTING is described under its own heading. But a newer art-process, based upon the same principle, or rather *direct* nature-engraving, has been invented by Mr. George Wallis. By this method, called by the inventor *autotypography*, drawings are so executed that they can be afterwards impressed or engraved in soft metal plates by an analogous process (although differing in details) to that employed in impressing natural objects. The drawings are executed on paper, sheet gelatine, and even on the plate-glass bed of the special machine. When on the former, a tint

is also impressed in the plate, which can be afterwards treated as a mezzotinto for the high lights, &c. The majority of the specimens exhibited by the inventor are from drawings executed on gelatine, with a suitable drawing material, which constitutes an important element in the invention. The most delicate touches, both of pen and brush, are transferred to the plate from this medium, which being transparent affords every facility for the accurate tracing of the design or writing; and as the subject is reversed in the process of impressing or engraving, an almost instantaneous operation, which takes up only two or three seconds, no reversal of the drawing or writing is required as in the case of ordinary engraving. The plates are printed from at an ordinary copper-plate press in the usual manner, and when the surface is hardened by a coating of steel or nickel, will yield a considerable number of impressions. The chief aim and merit of the invention is, that the original expression, spirit, and touch of the artist who executes the drawing are preserved and transmitted to the plate. The drawings are stated to be as easy of production, within certain well-defined limits, as those of ordinary pen and washed drawings. The cost of printing is of course that of ordinary plate printing; but as several plates can be engraved from the same drawing, the delay of printing from only one plate can be avoided without the cost of electrotyping.

By the process of *electro-block printing*, drawings, engravings, letterpress, or music, can be reproduced either greatly extended or reduced in size. To effect this on an enlarged scale, the surface of a sheet of vulcanised Indian rubber, equal in size to the subject, is coated with a thin film of an elastic composition, and on it is taken an impression of the print, block, or plate. This is done without difficulty, and without injury to the print from which it is taken. By means of an ingeniously contrived frame with a double-screw action, the Indian rubber is stretched equally on all sides to the size required. While retained in this form, it is laid down on a lithographic stone or zinc plate, properly prepared; and it is then in a condition to furnish impressions in the ordinary method. The reduction of objects is obtained by stretching the Indian rubber sheet of the size required till it can cover the subject; the impression being then taken, it is released from the strain and returns to its original size, and the process is continued as above described. For surface printing, some further operations are required. The impression of the desired size having been received on zinc plate or stone, the surface of either is exposed to the action of an acid which will eat away the parts of the surface unprotected by the ink, leaving the impression in relief. From this a matrix is taken, and an electrotype or a stereotype cast can be produced, fitted for any of the ordinary modes of type-printing.

Another contrivance for printing is that of M. Auguste Leouillet, of Paris. His *numéroteurs mécaniques* are made for numbering coupons, ailway certificates, and bank-notes, for paging account books, or for any other purpose for which a continuous series of numbers is required. It may be adapted either for use in the hand, or for printing in a press. The hand instrument consists of a rowel-formed circle, on the points of which are cut in steel the ten numerals. It turns on an axle which may hold from two to six or more of these rowels. The figure or figures that are to move are left free; those that are stationary are fixed by a screw at the side to prevent their being disturbed by the action of the others. The figure is changed by the action of a small lever that rises up by the wooden handle, the pressure of which turns the rowel so as to bring the next figure in its place, and at the same time inks itself from a small inking apparatus fixed above the figures. Thus, with six rowels, numbers 1 to 999,999 may be impressed, the first of the series appearing 000,001. This instrument may also be used dry for stamping anything where colour is not needed, but only an impression; or with common marking-ink for stamping bales or goods of wooden packing-cases. For printing, eight rowels with ten axils each may be used fixed in a form, or rather on a plate, furnished with spaces to admit the movable types. If we suppose that they number, as at first prepared, from 1 to 80, a horizontal handle moves all the necessary figures, and the next impression would give from 81 to 160. This process may be combined with the printing of labels requiring dates, such as those of the month and year. In such cases the necessary fixed type is prepared in the usual manner, and space is left for the numéroteurs to be inserted, which are then operated on in the manner already described.

Messrs. Waterlow and Sons exhibited at the Great Exhibition of 1862 a *railway ticket printing machine*, worked by steam, but which can easily be adapted to hand working. In it the fixed type is placed in a frame, and the movable figures or letters are engraved in steel on a brass rowel. By a vibrating action the frame is brought under a press to convey the impression to the paper, and the reversed movement brings the next type in succession to its place. It is self-inking.

Harrild's *newspaper addressing machine* consists of a sliding groove of some length, on which is placed a *galley* containing as many of the required directions as it will hold set up in type, and locked up. A treddle moves it along under a sort of parchment frisket or tympan, till a direction arrives just under the space cut in the frisket, the newspaper envelope is laid over the frisket, and the treddle brings down a pressure on it. The galley continues sliding on till all the directions have been impressed, when it is removed to make room for another.

Bank-note Printing.—The old method of printing bank-notes was from copper, and subsequently from steel, plates. But in the year

1853, Mr. Alfred Smee, surgeon to the Bank of England, suggested to the directors that the time had arrived for the adoption of *surface* printing instead of *plate* printing, in the preparation of the notes, as admitting of greater rapidity and more complete identity of appearance. Although objecting to any additional change in the form or device of the note, the directors consented to the prosecution of a series of elaborate experiments. In these experiments Mr. Smee was assisted by Mr. Hensman, engineer to the Bank, and by Mr. Coe, superintendent of the note-printing machines. Engravers, press-makers, paper-makers, and ink-makers, all contributed their opinions or inventions towards the preparation of bank-notes by surface printing. At length, in 1854, all the difficulties were surmounted: on January 1, 1855, the first bank-note appeared under the new system. The bank-note differs very little from its predecessor; the Britannia is, perhaps, somewhat more artistic; but the letters, figures, and flourishes are scarcely altered. Indeed, it was a fixed policy on the part of the directors to render any change in the appearance of their bank-notes as little perceptible as possible. The great novelty was in the preparation of the plate for surface-printing. Until the year 1837, the device was engraved on the plate itself from which the impressions were to be printed; from 1837 to 1854, the engraving was managed on the siderographic process; but on the new system, introduced in 1855, the design for the note is made up and engraved on several small pieces of copper, brass, and steel, according to the quality and minuteness of the engraving; the lines of the device being raised instead of sunken. From the model thus made a metallic mould is obtained, by electro-deposition. Mr. Smee's platinised silver voltaic batteries are employed as the source of power. These batteries had already been advantageously used in multiplying the copper-plates for the Ordnance maps. The model is left in the precipitating trough containing sulphate of copper solution until a layer of copper has been deposited upon it thick enough to bear handling; the device of course appears on this film in intaglio, not in relief, and serves as the mould from which copies of the original model are to be made. Being separated from the original model, and again immersed in the solution, this mould receives a deposit, which, when thick enough, is separated from the mould giving the device. It is this, in relief instead of intaglio, when backed up and strengthened by solder or other metal, which forms the plate from which Bank of England notes are printed. There are about seventy or eighty kinds of Bank of England notes, differing either in their denominations (5*l.*, 10*l.*, &c.), or in the town where they are issued (London, Manchester, Birmingham, &c.); each of these has required its own original model; but any one model would suffice for an almost endless number of notes—seeing that one model will yield an indefinite number of moulds, and one mould an indefinite number of plates. By the electro-metallurgic process, nearly ten million bank-notes are printed annually without any necessary renewal of the original models. The paper, supplied by the same establishment in Hampshire which has furnished bank-note paper for a long series of years, is manufactured in a manner which exhibits almost as many novelties as the preparation of the plates. Until the year 1855, the *water-mark* (one of the safeguards against forgery) was produced by forming a device with fine wire in the mould or frame employed in making the paper. Now, however, the device for the water-mark is engraved on steel-faced dies, and transferred by stamping to brass plates; by a delicate process these brass plates are adjusted to or within the paper-making mould. There is a gradation of light and shade in the present water-mark, very difficult to imitate. The sheets of paper, before they leave the Hampshire mill, undergo a process of dry-glazing by rolling. It has been necessary to make a change in the ink as well as in the paper, in adapting the arrangements for surface printing. The bank-note ink, instead of being prepared from the husks of Rhenish grapes, is now made by a combination of a peculiar varnish with the soot resulting from burning coal-tar naphtha in closed chambers. The printing presses, and the mode of printing, differ materially under the present surface-printing system, as compared with the old plate printing; the mechanism comprises many beautiful novelties.

Excellent as are now the Bank of England notes, there are not wanting experienced men who contend that a more elaborate device, practicable only by the plate-printing method, would be better. Forgery has diminished, but it has not quite died out. The Bank directors opposed any marked change in the simplicity of the device on these grounds: That forgers can imitate elaborate engraving sufficiently well to deceive the public, if not bank-clerks; that parti-coloured notes, invented by Sir William Congreve, were successfully imitated; that the general public, not being judges of artistic effect, and having little discrimination for the different styles of different artists, are apt to be easily deceived by the same *general* appearance in a forged note with which they have been familiar in a real note, and take imperfect imitations of it quite as readily; and that on the whole, long familiarity with one form of inscription and one style of ornament is the best preventive against forgery. These opinions were contested by the late Mr. Henry Bradbury, in a lecture delivered at the Royal Institution, on May 9, 1856; the lecture was afterwards printed as a quarto pamphlet, with engravings of three specimen bank-notes from designs by Mr. John Leighton. Mr. Bradbury contends that the object to be aimed at should be to impart to each bank-note an individuality, thereby expressing qualities which are not within the province of mechanical imitation. This is to be done by employing a design of a

high artistic character; seeing that the work which has the genius of an artist imprinted on it, is not to be imitated by an inferior mind. The vignette is the part of a note on which the most artistic skill is displayed; and Mr. Bradbury urges that this skill should be still further exercised. Early in the present century the Plymouth Dock Bank, to lessen the forgery of its notes, caused a vignette to be engraved; the forgeries at once ceased. When a really skilful artist can engrave a vignette of a high character, his social position and prospects are such as to take him out of the influence and temptation of forgers. The higher the class of the engraving, the less the likelihood of forgery; seeing that the work of every real artist has an individuality about it which others could not imitate. Admitting that the Bank of England note exhibits simplicity of design, Mr. Bradbury remarks, 'The objection I have to submit is that its simplicity is *too* simple—not having upon the face of it those features which characterise the true art-point. The vignette is a specimen the reverse of what I have been advocating; it is alike deficient in conception and execution. Surface-printing having been chosen as the medium, the Bank authorities were restricted in the application of their art. In consequence of this, the Bank of England note in its present form is unworthy of the bank and the nation.' Assuming that high art should be employed to give character to the simplest parts of the note, Mr. Bradbury would employ machine-engraving—such as medallion work, and guilloche or rose-engine work—to produce ornamental details of any desired degree of complexity; straight lines, waved lines, circles, ellipses, &c., may be combined in ways almost illimitable. To produce these results—the combination of high art and simplicity with mechanical intricacy, as a double check to the forger—Mr. Bradbury believes that plate-printing would be necessary. Mr. Grubb, engineer to the Bank of Ireland, has expressed opinions very similar to those of Mr. Bradbury. (Knight's *English Cyclopædia*.)

Laws affecting the Press.—These laws are 39 Geo. III. c. 79, amended by 51 Geo. III. c. 65, and 2 & 3 Vict. c. 12. There is no censorship over the press, which is, however, amenable to the remedy of an injured party, or to the correction of criminal justice. (Wharton's *Law Lex.* 2nd ed. 1860.)

Glossary of terms used in printing, most of them not explained in the body of this work:—

Ascending Letters. Capital letters and the following small ones: b, d, f, h, k, l. The *descending letters* are the g, j, p, q, y.

Astronomical Characters. The signs for the twelve zodiacal constellations, for the planets and dragon's head and tail, for the aspects, and for the moon in her various changes.

Author's Proof. The proof sheet or slips of a work corrected by the author himself.

Back Boxes. The compartments of the compositor's upper case not required for the ordinary types, but used for irregular sorts.

Bad Copy. Badly written or troublesome MS.

Batter. When the faces of types become injured in a form.

Beard of a Letter. The outer angle of the square shoulder of the shank of a type.

Benvenue Money. Money paid by a new hand to his fellow workmen, who spend it in beer. The term is evidently a corruption of *bien venu*, or welcome.

Bill. A weight of a fount of types, in certain fixed proportions. [TYPE.]

Blank Pages. Pages which do not print, made up of quadrats and furniture.

Bodkin. A sharp-pointed piece of steel wire, used for drawing letters out of a form in correcting. [CORRECTING.]

Body of a Work. The subject-matter of a book, without the title-page, preface, contents, introduction, and index.

Book. A complete copy of a work, the gatherings being put together ready for the bookbinder. This operation is called *booking*. The press used for pressing the books just before binding is called the *book press*.

Book House. A printing office in which book work is its chief employment. A *News House* is confined to newspaper printing.

Bottom Notes or *Foot Notes.* The notes at the foot of a page.

Brace. A character made to various lengths and bodies, thus ⏞.

Brass Rules. Pieces of brass of various fractional parts of a pica in thickness, type high, for printing lines.

Bringing up or *Making ready* a form of type. The operation of overlaying or underlaying, cutting out, &c. for equalising the impression, or bringing out the light and dark parts of woodcuts.

Cassie Paper. The two outer quires of a ream of paper.

Casting up. A calculation of the number of thousands of types contained in a sheet of a work, made for the purpose of ascertaining the value of the compositor's work.

Clean Proof. A sheet composed with very few errors, or a proof pulled after correction for the author.

Clicker. The compositor who has the management of a companionship, or number of men engaged in setting up one or more works.

Close Spacing. When thin and middling instead of thick spaces are used between words by the compositor. It is objectionable, as is also *open spacing*.

Cock-up Letter. A large letter, standing above the line, formerly used for the first word of a book.

Collate. To examine the signatures of a book, to see that it is complete and ready for the bookbinder.

Companionship. See *Clicker*.

Corrector. The old name for the reader, or person employed to detect the errors made by the compositor in setting up the types.

Dele. In correcting a proof, the mark thus ₰, expunging a letter or word.

Devil. In old times boys employed to take the printed sheets off the tympan of the press. They were commonly bedaubed with ink. *Taking-off* boys at machines are now called *flies* or *fly boys*.

Double. In composing, a word or words set up twice.

Drive out. To space widely, and also if copy makes more matter than was reckoned upon. The reverse is called *to get in*.

Even Lines. When work, such as newspaper composition, is in great haste, paragraphs are divided into a few lines to each man, and he is required to begin and end a line, often with very close or wide spacing.

Fat. With compositors, short or blank pages and widely leaded matter; and with the pressmen, small numbers paid as much as if 250 copies were worked off.

Fat-face. Thick-face types, giving very black impressions.

Fine Presswork. [PRINTING.]

Fire-eaters. Rapid compositors.

First Proof. The first impression pulled from the type after composition.

Fly Boys. See *Devil*.

Foot Notes. See *Bottom Notes.*

Fore Edge. The outer edge of a sheet when folded to the proper size of a book.

Foreign. All composition in foreign languages.

Fractions. Types cast in one piece representing $\frac{1}{8}$, $\frac{1}{4}$, $\frac{3}{8}$, $\frac{1}{2}$, $\frac{5}{8}$, $\frac{3}{4}$, $\frac{7}{8}$. *Half-fractions* are cast to one-half the body of a type, and make all kinds of combinations.

Fragments or *Oddments.* The few pages at the end of a book which do not make a sheet, and the title, preface, contents, &c., imposed so as to print off economically.

Frame. The kind of desk on which a compositor rests his cases.

French Rules. Dashes mostly of brass, thus: ——◆——.

Friar. A pale patch in a printed sheet where the form has not taken the ink as in the other parts. Black patches are called *monks.*

Frisket. An iron frame, covered with paper, and cut out to the sizes of the pages when being printed off, so as to keep the margin of the paper clean.

Full-face Letter. Types in which the ascending letters occupy the whole of the body, and the descending letters hang over, and are kerned.

Geometrical Characters. Types used for the *plus, minus,* &c.

Get in. See *Drive out.*

Good Copy. Well-written MS. or printed copy.

Gutter. The space between the pages forming the back margin of a book.

Horse. A charge made for work not done, a practice to be discouraged for obvious reasons. Also an apparatus, of a desk-like form, used by the pressman on which to lay his white paper.

Imperfect Paper. A ream containing only 480 sheets; *perfect paper* containing 516 sheets.

Imperfection. A sheet required by the bookbinder to make a volume complete. Types not cast up to the proper quantity are also so called.

Inner Form of a sheet. The form which begins with the second page, usually worked off first.

Letter. Type.

Literals. Errors made by compositors in single letters only.

Lye. A solution of alkali, used for cleaning the ink off the forms of type.

Macule. A faulty impression, appearing somewhat doubled in the printing off.

Make up. To put matter into pages.

Making ready. See *Bringing up.*

Margin. The white paper round the printed portion of a sheet.

Matter. Types set up.

Metal. Type metal, used also for stereotype plates.

Monk. See *Friar.*

Nick. The mark in a type by which the compositor sees which side to put into his stick in setting up. [TYPE.]

Oddments. See *Fragments.*

Oriental. Eastern languages.

Out. Matter omitted by the compositor in setting up.

Outer Form. The form beginning with the first page of the sheet, and worked off last.

Outside Quires. See *Cassie Paper.*

Overlays. Pieces of paper pasted on a sheet put between the tympans, for the purpose of obtaining a regular and flat impression.

Overrun. To carry over parts of lines or pages.

Overseer. The manager of a printing office.

Pamphlet. A work consisting of more than one sheet, but not more than five sheets.

Perfect Paper. See *Imperfect Paper.*

Periodicals. Works published at stated intervals, but neither newspapers nor those which are proposed to be finished in a certain number of parts.

Picker. A man who corrects stereotype plates.

Picks. Dirt in a form, or metal flaws in stereotype plates.

Pie. Broken matter.

Plane down. To flatten the face of the form of type.

Platen. That part of the press which comes down upon the form, producing the impression.

Point Holes. Holes made in working off a sheet of white paper, so that when the outer form is worked the pages shall fall in register.

Pull. To take an impression.

Reader. See *Corrector.*

Register, to make. To arrange the pages of both sides of a sheet so that they shall fall precisely upon one another.

Reiteration. The outer form, or second form worked off; called also, by abbreviation, the *ret.*

Revise. A proof pulled after the corrections have been made by the compositor.

Set off. The ink from one recently printed sheet coming off upon and spoiling another.

Slur. An impression smeared at press.

Specimen Page. A page pulled neatly on good paper to show the proposed size and type.

Stet. [CORRECTING.]

Taking. A portion of copy given to a compositor at one time.

Token. Ten quires of paper.

Two-line Letters. The large types sometimes used at the beginning of a book or chapter, and occupying two or more lines in depth.

Tympan. The parchment frame on which the sheet to be printed is laid at press.

Underlays. Pieces of paper pasted under pages or woodcuts to bring them up to the required height.

White line. A line of quadrats producing a blank the depth of a line of print.

Printing Balls or Rollers. The balls by which the ink was formerly applied to the forms in presswork [PRINTING] were made of a sort of wooden funnel with handles, the cavities of which were filled with wool or hair, and a piece of felt or leather nailed over the cavity, and made extremely soft by soaking in urine and being well rubbed. One of these the pressman took in each hand, and, applying them to the ink-table, daubed and knocked them together, to distribute the ink equally, and then blacked the form, by beating with balls upon the face of the letter. A considerable improvement upon this plan has been effected by means of rollers, invented by Mr. B. Foster, and now and for some years past in general use. These rollers consist of a combination of treacle and glue, which runs on the ball stock, a cylinder of wood covering an iron rod, affixed to which are two handles. Instead of beating, as in the case of balls, the cylinder is rolled over the face of the form, and the ink thereby applied in a much more even manner, and with a considerable decrease of labour. Experience, however, teaches us that the ball is the best means of inking fine wood engravings and producing the most brilliant impressions.

The best method of keeping a roller in good condition is to smother it in common ink when out of use, hanging it up in a cool place in warm weather, and in a warm place in cool weather, but never in a draught or current of air.

Printing Ink. The black ink used in printing books is prepared from certain quantities of linseed oil, black resin, soap, and lampblack. An excellent black ink has been made by Mr. Savage, who gives the following

opinions as to the requisites of black printing ink for fine work: 'Intenseness of colour, impalpability, covering the surface of the type or engraving perfectly, quitting the surface of the type or engraving when the paper is pressed upon it and adhering to the paper, not smearing after it is printed, and retaining its appearance without any change. The linseed oil is boiled, and after the smoke begins to rise from the boiling liquid, a bit of burning paper stuck in the cleft end of a long stick should be applied to the surface, to set it on fire, as soon as the vapour will burn; and the flame should be allowed to continue (the pot being meanwhile removed from over the fire, or the fire taken from under the pot), till a sample of the varnish, cooled upon a pallet-knife, draws out into strings of about half an inch long between the fingers. To six quarts of linseed oil thus treated, six pounds of resin should be gradually added, as soon as the froth of the ebullition has subsided. Whenever the resin is dissolved, one pound and three-quarters of dry brown soap, of the best quality, cut into slices, is to be introduced cautiously, for its water of combination causes a violent intumescence. Both the resin and soap should be well stirred with a spatula. The pot is to be now set upon the fire again, in order to complete the combination of all the constituents. Put next of well-ground indigo and Prussian blue, each 2½ ounces, into an earthen pan, sufficiently large to hold all the ink, along with 4 pounds of the best mineral lampblack, and 3½ pounds of good vegetable lampblack; then add the warm varnish by slow degrees, carefully stirring, to produce a perfect incorporation of all the ingredients. This mixture is next to be subjected to a mill, or slab and muller, till it be levigated into a smooth uniform paste.'

The following is Mr. Savage's recipe for making one pound of superfine printing ink: Balsam of capivi, 9 ounces; lampblack, 3 ounces; indigo and Prussian blue together, p. seq. 1¼ ounce; Indian red, ¾ ounce; turpentine (yellow) soap, dry, 3 ounces. This mixture is to be ground upon a slab, with a muller, to an impalpable smoothness. The pigments used for colouring printing inks are, carmine, lakes, vermilion, red lead, Indian red, Venetian red, chrome yellow, chrome red or orange, burnt terra di Sienna, gall-stone, Roman ochre, yellow ochre, verdigris, blues and yellows mixed for greens, indigo, Prussian blue, Antwerp blue, umber, sepia, &c.

In consequence of the late immense rise in the prices of the materials for making ink, experiments are said to have been made on petroleum, gas refuse, &c., and the ink thus produced has been mixed with the genuine. These filthy compositions spoil the books in which they are used, exhibiting a disagreeable-looking halo round the print, and imparting a most unpleasant odour to the volume when opened.

Printing Machine. The earliest printing presses were the common wooden screw press, for the first essential modification of which the world is indebted to the late Earl Stanhope [PRESS.] In Dr. Dibdin's *Bibliographical Decameron* may be seen cuts of the earliest printing presses.

Prior to the introduction of printing machines presswork was one of great labour whenever extraordinary expedition was required. It was particularly the case with newspapers, of which, with the utmost exertion, scarcely more than 750 copies per hour could be obtained; the consequence was that in newspaper offices where the circulation was extensive, it was found necessary, in order to get the paper published in time, to compose two or more sets of types, and work them off simultaneously at as many presses. An enormous increase in the composition and presswork was the result.

In describing the various machines, it will be observed that in the diagrams illustrating their leading principles or arrangements—

The black parts represent the inking apparatus.

The diagonal lines represent the paper cylinders which give the impression.

The perpendicular lines represent the types or plates.

The arrows represent the track of the sheet of paper.

In the year 1790 Mr. W. Nicholson, the editor of the *Philosophical Journal*, took out a patent for certain improvements in printing; and, on reading his specification, everyone must be struck with the extent of his ideas on the subject. To him belongs, beyond doubt, the honour of the first *suggestion* of printing by means of cylinders; the following are his own words, divested of legal redundancies:—

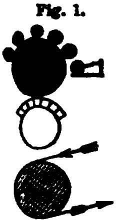
'In the first place, I not only avail myself of the usual meth ds of making type, but I likewise make and arrange them in a new way, viz. by rendering the tail of the letter gradually smaller. Such letter may be imposed on a cylindrical surface; the disposition of types, plates, and blocks, upon a cylinder, are parts of my invention.

'In the second place, I apply the ink upon the surface of the types, plates, &c. by causing the surface of a cylinder smeared with colouring matter to roll over or successively apply itself to the surface of the types, &c., or else I cause the types to apply themselves to the cylinder. It is absolutely necessary that the colouring matter be evenly distributed over this cylinder, and for this purpose I apply two, three, or more smaller cylinders, called distributing rollers, longitudinally against the colouring cylinders, so that they may be turned by the motion of the latter; if this colouring matter be very thin, I apply an even blunt edge of metal or wood against the cylinder.

'In the third place, I perform all my impressions by the action of a cylinder, or cylindrical surface, i. e. I cause the paper to pass between two cylinders, one of which has the form of types attached to it, and forming part of its surface, and the other is faced with cloth, and serves to press the paper so as to take off an impression of the colour pre-

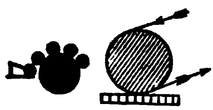
viously applied; or otherwise, I cause the form of types, previously coloured, to pass in close and successive contact with the paper wrapped round a cylinder with woollen cloth.' He also described a method of raising the paper cylinder to prevent the type from soiling the cloth.

Fig. 1.



Nicholson's arrangement for arched type.

Fig. 2.



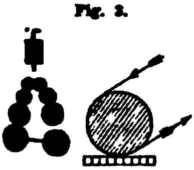
Nicholson's arrangement for common type.

This specification describes the principal parts of modern printing machines; and had Mr. Nicholson paid to any one part of his invention that attention which he fruitlessly bestowed on attempts to fix types on a cylinder, or had he known how to curve stereotype plates, he would, in all probability, have been the first *maker* of a printing machine, instead of merely suggesting the principles on which they might be constructed.

The first working printing machine was the invention of Mr. T. Kœnig, a native of Saxony; he submitted his plans to Mr. T. Bensley, the celebrated printer, and to Mr. R. Taylor, the scientific editor of the *Philosophical Magazine*. These gentlemen liberally encouraged his exertions, and in 1811 he took out a patent for improvements in the common press, which, however, produced no favourable result. He then turned his attention to the use of a cylinder, in order to obtain the impression, and two machines were erected for printing the *Times* newspaper, the readers of which were told, on the 28th of November, 1814, that they held in their hands a newspaper printed by machinery, and by the power of steam.

In these machines the type was made to pass under the cylinder, on which was wrapped the sheet of paper, the paper being firmly held to the cylinder by means of tapes. The ink was placed in a cylindrical box, from which it was forced by a powerful screw, depressing a tightly fitted piston; thence it fell between two iron rollers. Below these were placed a number of other rollers, two of which had, in addition to their rotatory motion, an end motion, i. e. a motion in the direction of their length. The whole system of rollers terminated in two, which applied the ink to the types. In order to obtain a great number of impressions from the same form, a paper cylinder (i. e. a cylinder in which the paper is wrapped) was placed on each side of the inking apparatus, the form passing under both. The machine produced 1,100 impressions per hour; subsequent improvements raised them to 1,800 per hour.

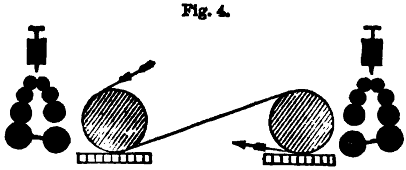
Fig. 3.



Kœnig's single, for one side of the sheet.

The next step was the invention of a machine (also by Mr. Kœnig) for printing both sides of the sheet: it resembled two single machines, placed with their cylinders towards each other, at a distance of two or three feet. The sheet was conveyed from one paper cylinder to the other by means of tapes; the track of the sheet exactly resembled the letter S, if laid horizontally, thus, ∞. In the course of this track the sheet was turned over. At the first paper cylinder it received the impression from the first form, and at the second paper cylinder it received the impression from the second form; the machine printed 750 sheets, on both sides, per hour. This machine was erected for Mr. T. Bensley, and was the only one made by Mr. Kœnig for printing on both sides of the sheet: this was in 1815.

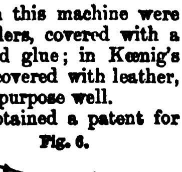
Fig. 4.



Kœnig's double, for both sides of the sheet.

About this time Messrs. Donkin and Bacon were also contriving a printing machine, having in 1813 obtained a patent for a machine in which the types were placed upon a revolving prism. The ink was applied by a roller, which rose and fell with the irregularities of the prism; and the sheet was wrapped on another prism, so formed as to meet the irregularities of the type prism. One of these machines was erected for the university of Cambridge, and was a beautiful specimen of ingenuity and workmanship; it was, however, too complicated, and the inking was defective, which prevented its success. Nevertheless, a great point was attained; for in this machine were first introduced inking-rollers, covered with a composition of treacle and glue; in Kœnig's machine the rollers were covered with leather, which never answered the purpose well.

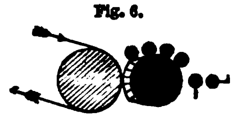
Fig. 5.



Donkin and Bacon's machine for type.

In 1815 Mr. Cowper obtained a patent for curving stereotype plates for the purpose of fixing them on a cylinder. Several of these machines, capable of printing 1,000 sheets per hour on both sides, are at work at the present day;

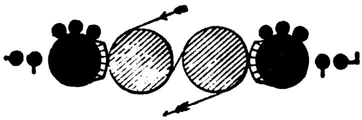
Fig. 6.



Cowper's single, for curved stereotype.

and twelve machines on this principle were made for the Bank of England a short time previous to the issue of gold.

Fig. 7.



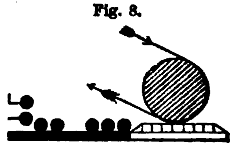
Cowper's double, for both sides of the sheet.

It is worthy of note that the same object seems to have occupied the attention of Nicholson, Donkin and Bacon, and Mr. Cowper, viz. the revolution of the form of types. Nicholson sought to do this by a new kind of type, shaped like the stones of an arch. Donkin and Bacon sought to do this by fixing types on a revolving prism; and at last it was completely effected by the curving of a stereotype plate by Mr. Cowper.

In these machines two paper cylinders are placed side by side, and against each of them is placed a cylinder for holding the plates. Each of these four cylinders is about two feet diameter; on the surface of the plate cylinder are placed four or five inking-rollers, about three inches diameter; they are kept in their position by a frame at each end of the plate cylinder, the spindles of the rollers lying in the notches on the frame, thus allowing perfect freedom of motion, and requiring no adjustment. The frame which supports the inking-rollers, called the *waving-frame*, is attached by hinges to the general frame of the machine; and the edge of the plate cylinder is indented, and rubs against the waving-frame, causing it to wave or vibrate to and fro, and, consequently, to carry the inking-rollers with it, thus giving them a motion in the direction of their length, called the *end motion*. These rollers distribute the ink upon three-fourths of the surface of the plate cylinder, the other quarter being occupied by the curved stereotype plates. The ink is held in a trough; it stands parallel to the plate cylinder, and is formed by a metal roller revolving against the edge of a plate of iron. In its revolution this roller becomes covered with a thin film of ink, which is conveyed to the plate cylinder by an inking-roller vibrating between both. On the plate cylinder the ink becomes distributed, as before described, and as the plates pass under the inking-rollers they become charged with colour. As the cylinders continue to revolve, the plates come in contact with a sheet of paper in the first paper cylinder, whence it is carried, by means of tapes, to the second paper cylinder, where it receives an impression on its opposite side from the plates on the second plate cylinder, and thus the sheet is perfected. These machines are applicable only to stereotype plates, but they formed the foundation of the future success of Applegath and Cowper's printing machinery, by showing the best method of furnishing, distributing, and applying the ink.

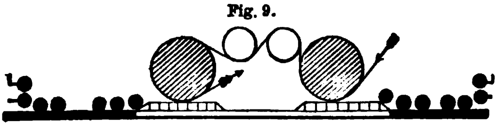
In order to apply this method to a machine capable of printing from type, it was only necessary to do the same thing in an extended flat surface or table, which had been done on an extended cylindrical surface. Accordingly Mr. Cowper constructed a machine for printing both sides of the sheet from type, securing by patent the inking apparatus, and the mode of conveying the sheet from one paper cylinder to the other by means of drums and tapes.

Fig. 8.



Applegath and Cowper's single machine.

Fig. 9.



Applegath and Cowper's double machine.

Mr. A. Applegath, who was a joint proprietor with Mr. Cowper in these patents, obtained patents for several improvements. Mr. Cowper had given the end motion to the distributing rollers by moving the frame to and fro in which they were placed. Mr. Applegath suggested the placing of these rollers in a diagonal position across the table, thereby producing their end motion in a simpler manner.

The diagonal rollers have an admirable tendency to spread out the ink in a smooth stratum, by the sliding of the table in a different direction to the lines of revolution; but there must be considerable friction at their axes by the constant tendency of the table to thrust the rollers sideways or endways, which must be provided against, or they will soon wear untrue. He also contrived a method of applying two feeders to the same printing cylinder; these latter inventions are more adapted to newspaper than to book printing. Numerous machines have been constructed upon the joint inventions of Messrs. Applegath and Cowper, which are modified in a great number of ways for the various purposes of printing books, bank-notes, newspapers, &c.; they have, in fact, superseded Mr. Kœnig's machines in the office of Mr. Bensley (who was the principal proprietor of Kœnig's patent), and also in the office of the *Times*, as was announced in that journal. No less than forty wheels were removed from Kœnig's machines when Mr. Bensley adopted the improvements of Messrs. Cowper and Applegath.

Having, on the first trial of their machines, discovered the superiority of the inking roller and table over the common balls, they immediately applied them to the common press, and with complete success. The invention, however, was immediately infringed throughout the kingdom, and copied in France, Germany, and America; and it would have been as fruitless to attempt to stop the infringement of the patent as it was found in the case of the kaleidoscope. This invention has raised the quality of printing generally.

Improvements in printing machines were effected by Mr. Wayte and by Mr. David Napier; but the immense and increasing demand of the *Times* upon their powers, rendered it necessary to provide a machine which would *work off from* 12,000 *to* 15,000 *copies per hour*. This demand was supplied by the invention of the late Mr. Applegath, who gave the author the following description, first published by the late Dr. Lardner: He decided on abandoning the reciprocating motion of the type form, arranging the apparatus so as to render the motion continuous. This necessarily involved circular motion, and accordingly he resolved upon attaching the columns of type to the sides of a large drum or cylinder, placed with its axis vertical, instead of the horizontal frame which had been hitherto used. A large central drum is erected, capable of being turned round its axis. Upon the sides of this drum are placed vertically the columns of type. These columns, strictly speaking, form the sides of a polygon, the centre of which coincides with the axis of the drum, but the breadth of the columns is so small compared with the diameter of the drum, that their surfaces depart very little from the regular cylindrical form. On another part of this drum is fixed the inking table. The circumference of this drum in the *Times* printing machine measures 200 inches, and it is consequently 64 inches in diameter. This drum is surrounded by eight cylinders, also placed with their axes vertical, upon which the paper is carried by tapes in the usual manner. Each of these cylinders is connected with the drum by toothed wheels, in such a manner that their surfaces respectively must necessarily move at exactly the same velocity as the surface of the drum. And if we imagine the drum thus in contact with these eight cylinders to be put in motion, and to make a complete revolution, the type form will be pressed successively against each of the eight cylinders, and if the type were previously inked and each of the eight cylinders supplied with paper, eight sheets of paper would be printed in one revolution of the drum.

It remains, therefore, to explain, first, how the type is eight times inked in each revolution; and secondly, how each of the eight cylinders is supplied with paper to receive their impression. Beside the eight paper cylinders are placed eight sets of inking rollers; near these are placed two ductor rollers. These ductor rollers receive a coating of ink from reservoirs placed above them. As the inking table attached to the revolving drum passes each of these ductor rollers, it receives from them a coating of ink. It next encounters the inking rollers, to which it delivers this coating. The types next, by the continued revolution of the drum, encounter these inking rollers, and receive from them a coating of ink, after which they meet the paper cylinders, upon which they are impressed, and the printing is completed.

Thus in a single revolution of the great central drum the inking table receives a supply eight times successively from the ductor rollers, and delivers over that supply eight times successively to the inking rollers, which, in their turn, deliver it eight times successively to the faces of the type, from which it is conveyed finally to the eight sheets of paper held upon the eight cylinders by the tapes.

Let us now explain how the eight cylinders are supplied with paper. Over each of them is erected a sloping desk, upon which a stock of unprinted paper is deposited. Beside this desk stands the *layer on*, who pushes forward the paper, sheet by sheet, towards the fingers of the machine.

These fingers, seizing upon it, first draw it down in a vertical direction between tapes in the eight vertical frames until its vertical edges correspond with the position of the form of type on the printing cylinder. Arrived at this position, its vertical motion is stopped by a self-acting apparatus provided in the machine, and it begins to move horizontally, and is thus carried towards the printing cylinder by the tapes. As it passes round this cylinder it is impressed upon the type, and printed. It is then carried back horizontally by similar tapes on the other side of the frame, until it arrives at another desk, where the *taker off* awaits it. The fingers of the machine are there disengaged from it, and the *taker off* receives it, and disposes it upon the desk. This movement goes on without interruption; the moment that one sheet descends from the hands of the *layer on*, and being carried vertically downwards begins to move horizontally, space is left for another, which he immediately supplies, and in this manner he delivers to the machine at the average rate of two sheets every five seconds; and the same delivery taking place at each of the eight cylinders, 16 sheets are delivered and printed every five seconds. It is found that by this machine in ordinary work *between* 10,000 *and* 11,000 *per hour can be printed*; but with very expert men to deliver the sheets, a still greater speed can be attained. Indeed, the velocity is limited, not by any conditions affecting the machine, but by the power of the men to deliver the sheets to it.

In case of any misdelivery a sheet is spoiled, and, consequently, the effective performance of the machine is impaired. If, however, a still greater speed of printing were required, a machine of the same kind, without changing its principle, would be sufficient for the exigency;

but it would be necessary that the types should be surrounded with a greater number of printing cylinders.

It may be right to remark, that these surrounding cylinders and rollers, in the case of the *Times* machine, are not uniformly distributed round the great central drum; they are so arranged as to leave on one side of that drum an open space equal to the width of the type form. This is necessary in order to give access to the type form so as to adjust it.

One of the practical difficulties which Mr. Applegath had to encounter in the solution of the problem, which he has so successfully effected, arose from the shock produced to the machinery by reversing the motion of the horizontal frame, which in the old machine carried the type form and inking table, a moving mass which weighed one ton! This frame had a motion of 88 inches in each direction, and it was found that such a weight could not be driven through such a space with safety at a greater rate than about 45 strokes per minute, which limited its maximum producing power to 5,000 sheets per hour.

Another difficulty in the construction of this vast piece of machinery was so to regulate the self-acting mechanism that the impression of the type form should always be made in the centre of the page, and so that the space upon the paper occupied by the printed matter on one side may coincide exactly with that occupied by the printed matter on the other side. The type form fixed on the central drum moves at the rate of 70 inches per second, and the paper is moved in contact with it of course at exactly the same rate. Now, if by any error in the delivery or motion of a sheet of paper it arrive at the printing cylinder 1-70th part of a second too soon or too late, the relative position of the columns will vary by 1-70th part of 70 inches—that is to say, by one inch. In that case the edge of the printed matter on one side would be an inch nearer to the edge of the paper than on the other side. This is an incident which rarely happens, but, when it does, a sheet is, of course, spoiled. The waste, however, from that cause is considerably less in the present vertical machine than in the former less powerful horizontal one.

The vertical position of the inking rollers is more conducive to the goodness of the work—for the type and engraving are only touched on their extreme surface—than the horizontal machine, where the inking rollers act by gravity; while any dust shaken out of the paper, which formerly was deposited upon the inking rollers, now falls upon the floor. With this machine 50,000 impressions have been taken without stopping to brush the form or table.

The principle of this vertical cylinder machine is capable of almost unlimited extension.

Notwithstanding the great powers of production of Mr. Applegath's machine, the still-increasing requirements of the *Times*, with the repeal of the paper duty and the consequent demands of the cheap newspapers, made it necessary that something more should be done. An American machine, the invention of Messrs. Hoe and Co. of New York, has been recently introduced into this country, and several have been constructed by Mr. Whitworth of Manchester for the *Times* and other newspapers. By means of these machines, combined with a recently discovered process of stereotyping and multiplying type-high forms, there is practically no limit to the number of copies of a newspaper which can be produced within a given time.

The printing presses of Messrs. Hoe and Co. had, like Applegath's vertical machines, been invented previous to 1851, and cannot therefore be regarded as novelties; but at that date only one had been introduced into Europe, and no sample or even model was exhibited in Hyde Park. There was a small model of the ten-cylinder press in the Exhibition of 1862, but nothing else to illustrate the mechanism by which the principal newspapers of the metropolis and great provincial towns are printed. The first presses sent by Messrs. Hoe and Co. to this country were for *Lloyd's Weekly Newspaper*, and were of the six-cylinder size. These were followed by two ten-cylinder machines ordered by Mr. Walter for the *Times*, with the condition that they were to be made by an English machinist who should be approved by him. The *Star* and the *Manchester Examiner* also ordered Hoe presses of English make, and the example thus set was speedily followed by the *Manchester Guardian*, the *Daily Telegraph*, the *Scotsman*, the *Illustrated London News*, and in fact all the leading papers in the United Kingdom. The experience, however, of the English-made machines, had meanwhile (probably from the novelty of the manufacture) not been quite so satisfactory as that of those produced by Messrs. Hoe and Co., and this gave a decided preference to the New York machines. Mr. Walter still continues to use two of Applegath's eight-cylinder vertical machines in printing the *Times* and *Evening Mail*, but only as subsidiaries, the chief burden of the work falling on the two ten-cylinder Hoes made by Mr. Whitworth, and these are now said to perform admirably. They are driven at the rate of thirty-two revolutions per minute, which gives a printing rate of 19,200 per hour, or about 16,000 including stoppages. Much of the ingenuity exercised both in the Applegath and Hoe machines was directed to the chase, which had to hold securely upon its curved face the mass of movable type required to form a page. The complicated contrivances by which this was effected have now been entirely superseded by the use of stereotype plates; but before proceeding to describe the process by which these are obtained, it may be well to draw attention to some of the points which seem to have determined the preference now given to the Hoe presses over the Applegath. The course of the sheet in *laying on* at the Hoe machine is as direct as it can be made, short of printing from a continuous web,

and the taking off is performed with great regularity by means of a wooden frame, which rises and falls with each impression of the printing cylinders. At the Applegath press the direction of the sheet has to be changed from a perpendicular to a lateral motion to correspond with the vertical position of the main drum. A taker off is also required for each impression cylinder as well as a layer on, thus considerably increasing the number of hands. The American machine also possesses a decided superiority in the arrangements for securing good register, though the ingenious finger motion by which this result is obtained becomes objectionably rapid in the largest size of presses. For the mode of producing the plates for the *Times* and other newspapers, see STEREOTYPING.

The Spottiswoode Press.—The first successful application of steam, as a motive power, to printing presses with a *platen* and vertical pressure, was made in the establishment where this Dictionary is printed. Convinced of the superiority of the impression made by flat as compared with that of cylindrical pressure, the late Mr. Andrew Spottiswoode (a name to be remembered amongst the most eminent in his profession), assisted by his chief engineer, Mr. Brown, succeeded, after many experiments, in perfecting a machine which combines the excellence of work of the hand press with four times its speed, and with a uniformity of colour which can never be attained by inking by hand. The main point of the invention is the endless screw or drum which takes the carriage and type from each end under the platen, and after the impression is taken by means of a crank returns it to its original position. The frisket is attached to the tympan at the bottom near the tympan joints, so that when the tympan is lifted from the form by the machinery, the tympan and frisket open at the upper end, contrary to the usual way in presses worked by manual labour, and the printed sheet is left on the tympan resting on the frisket. These presses are called *double platens*; but they ought, in honour of their inventor, to be named Spottiswoode presses.

Printing, Nature. [NATURE PRINTING.]

Prior. [ABBOT.]

Prioress. The superior of certain convents of nuns.

Prisage (Fr. prise, *a taking*). An ancient right of the crown, by which the king or his butler was empowered to take two tuns of wine from every ship importing twenty tuns or more into England. It is mentioned in the earliest pipe rolls as a source of royal revenue. By a charter of Edward I. it was commuted to a tax of two shillings on every tun of wine imported by merchant strangers. The commutation, on the presumption that thirty to forty tuns were the average lading of a ship carrying Bordeaux or Gascony wine, is pretty nearly equivalent to the ordinary price of wine at the latter end of the thirteenth century, i.e. sixty to eighty shillings would have purchased, and frequently did purchase, two tuns of 252 gallons each. This low price of wine was partly due to the fact that French wine was freely consumed in England six hundred years ago, partly to the political connection which subsisted between this country and Guienne up to the latter part of the fourteenth century. After the rupture of the peace of Bretigny, and the reduction of Guienne, French wine became much dearer. [WINE.]

Priscillianists. In Ecclesiastical History, a sect of the fourth century; so named from Priscillian, a Spanish bishop, put to death in A.D. 382 by Maximus, tyrant of Gaul, on the accusation of another bishop, Ithacius; the earliest instance of anyone put to death for heresy. The opinions of Priscillian and his followers are said to have been Manichæan; but it is remarkable that Sulp. Severus, himself sufficiently zealous against their doctrines, admits that their persecutor Ithacius was a man of disreputable character, and that purity and austerity of manners were often sufficient with him to ground an accusation of Priscillianism. This affords a curious parallel with the history of the twelfth and thirteenth centuries, when accusations of Manicheism were liberally brought against sectaries whose avowed tenets extended only to the reformation of ecclesiastical matters and denial of the church's authority. (Milman's *Latin Christianity*, bk. ii. ch. iv.)

Prism (Gr. πρίσμα, from πρίω, *I saw*). In Dioptrics, a piece of glass or other diaphanous substance, more or less long, with triangular ends, employed to separate a ray of light into its constituent parts or colours by refraction. The prism is the instrument by means of which many of the remarkable phenomena of light and colours are exhibited. [CHROMATICS; OPTICS; REFRACTION.]

PRISM. In Geometry, a polyhedron, two of whose faces are equal, similar, and parallel, while all the rest are parallelograms. Prisms take particular names from the figures of their ends, or opposite equal and parallel sides. When the ends are triangles, they are called *triangular* prisms; when the ends are square, *square* prisms; when the ends are pentagonal, *pentagonal* prisms; and so on. A *right* prism has its sides perpendicular to its ends; an *oblique* prism is that of which the sides are oblique to the ends. The solid content of a prism is found by multiplying the area of the base into the perpendicular altitude; hence all prisms are to one another in the ratio compounded of their bases and altitudes.

Prismatic Analysis. The resolution of a beam of light into its constituent rays of different refrangibility. [CHROMATICS; SPECTRUM ANALYSIS.]

Prismatic Colours. The colours produced by decomposing light by a prism. [PRIMARY COLOURS and CHROMATICS.]

Prismatic Compass. A surveying instrument, much used, on account of its convenient size and form, in military sketching, and for filling up the details of a map where

great accuracy is not required. The construction is as follows: The compass-card, divided into degrees and minutes, is attached to the needle and turns with it. On one side of the compass-box stands a perpendicular slip, called the *sight-vane*, having a long narrow perpendicular slit in it, along the middle of which a fine thread is stretched. On the side of the box opposite to the sight-vane, there is a prism, through which and through the sight-vane an object is observed, and bisected by the thread. The use of the prism is this: the rays of light passing from the thread to the eye are refracted in passing through the prism, so that the thread appears to be prolonged and to intersect the circle on the card on which the divisions are; consequently, the magnetic azimuth of any object which the thread bisects is indicated immediately by the division with which the thread coincides. The angle between two stations is thus obtained, being equal when the stations are on opposite sides of the meridian to the sum of their azimuths, and to the difference of the azimuths when they are on the same side of the meridian. The card is divided to 15′ of a degree, which is, perhaps, a smaller angle than can be measured by this instrument. (Simm's *Treatise on Mathematical Instruments*.)

Prismoid. An imperfect prism; a figure resembling a prism, but not answering exactly to the definition.

Prison (Fr. prendre, *to take*). Imprisonment is commonly used in civilised states for three purposes: for safe custody of persons charged with offences, for the detention of debtors, and for punishment; under which latter head the reformation of prisoners must be comprehended, as an adjunct to punishment. The first principles of order seem to require that these three classes of prisoners should be kept entirely distinct, and, if possible, in separate places of confinement; but even the former rule has been generally very imperfectly observed, while the latter is in most places impracticable by reason of expense. The alleviation of the horrors of imprisonment, by physical improvement of the condition of prisoners and the imparting of religious instruction, has been from very early times an object with philanthropists; but the adaptation of imprisonment to serve the end of punishment has been, comparatively speaking, only very recently attempted. The Society of the Brothers of Mercy, in Italy, paid much attention to the former subject in the fifteenth and sixteenth centuries; and the names of Carlo Borromeo and Vincent de Paul have derived from it much of their lustre. But the earliest instance of a prison managed on any principles of policy and humanity seems to be that of the Penitentiary at Amsterdam, erected in 1595; an example which was soon followed by some of the German towns, especially Hamburg and Bremen. In England it is well known that the impulse of prison improvement was first communicated by the celebrated Howard, whose sufferings, when taken by a privateer and imprisoned at Brest, during the Seven Years' War, are said to have first directed his attention to the subject. The fruits of his observations, in his repeated visits to most of the prisons of Europe, were given to the world partly in his publications, and partly on examination before a committee of the House of Commons in 1774. To his suggestions, and those of Jonas Hanway, are principally owing the provisions of the 19 Geo. III. c. 74 (passed in 1778), truly called the basis of succeeding legislation on the subject. Solitary imprisonment was then first instituted. The works of Neeld and others, and the labours of the Prison Discipline Society (founded, we believe, chiefly by Mr. Fowell Buxton), kept the attention of the public fixed on the subject. In 1813, the construction of the Millbank Penitentiary was begun. This establishment was designed to serve as a species of model prison; but from many errors committed in its foundation and first management, it was long before it answered in any degree the views of its projectors. Meanwhile practical improvement has proceeded much further in the United States of America, where the experiments of solitary confinement and of association in silence were both first instituted on an extensive scale, and have formed the basis of two different systems, which now divide the suffrages of observers. Europe took in this matter lessons from America; and the reports of French visitors to its prisons, especially Messrs. Beaumont and De Tocqueville, 1834, contributed largely to the formation of public opinion on the subject. In 1834, inspectors were appointed to report annually on the state of English and Scottish prisons—a measure which had been earlier adopted with reference to Ireland. The chief heads of improvement in prison discipline then recommended or introduced were: 1. Inspection and control; 2. Classification; 3. Separate or solitary punishment; 4. The *silent* or non-intercourse system; 5. The introduction of labour; 6. Religious and intellectual instruction.—1. The first of these is matter rather of practical than theoretical developement. The history of the plan originally suggested by Sir Samuel Bentham and his brother, Jeremy Bentham the philosopher, which has formed, to a certain extent, the basis of later experiments, is mentioned under the head Penitentiary. 2. Classification, under the English Gaol Acts of 1823 and 1824, has been extensively introduced into prisons. It is, of course, a great improvement on the indiscriminate mixture of prisoners of all classes and characters which formerly prevailed; but as a means of reformation, or of punishment, it has not answered the views once entertained of it. And the reason is obvious: the only object of classification is the exclusion of the moral influence of more or less corrupted minds; but by no system of classification (and as many as fifteen classes have been introduced in some prisons) can this be excluded. In every class, whether arranged according to age,

or degree of offence, or in any other practicable mode, there will probably be some unusually depraved characters; and then the experiment must fail. The only perfect classification is that which constitutes the basis of, 3. The *separate* system; namely, the entire separation of prisoners from each other in solitary cells. When this has been carried to excess as a means of punishment, namely, seclusion by day and by night, without labour, without employment, with only the occasional silent visits of the turnkey or the medical attendant, it has generally proved more than human nature can bear, at least for any considerable time; but separate confinement *with* labour as an alleviation, and with occasional visits for religious instruction, is a very different mode of treatment. The separate system was specially established in the great eastern penitentiary of Philadelphia, and in that of Glasgow. 4. The difficulty of enforcing solitary confinement, in some American prisons, seems to have led to the adoption of the *silent* system: of which the prison at Auburn, in Pennsylvania, affords the most celebrated instance. The prisoners work together in the day, but are prevented from all communication: at night they are separate. It was, we believe, introduced several years ago in the Maison de Force at Ghent. In England, it is in operation at Coldbath Fields, Wakefield, and elsewhere. With respect to the comparative advantages of the two systems, the work of Messrs. Beaumont and De Tocqueville may be consulted for an impartial summary of evidence, without the expression of decided opinion. (Part i. chap. ii. s. 3.) The chief objections to the separate system are: (1) As a punishment, its inequality, being felt far more severely by some than others; but to this it may be answered, that those who do feel it are precisely those whom it is most desirable to affect—the more depraved. (2) Its effects on the mind and passions; a very difficult and delicate subject, and by far the most serious charge against it. (3) That even as a system of reform, for which, in subjects presenting any prospect of amendment, it is best calculated, it is utterly useless in short terms of imprisonment. To the silent system, its enemies object: (1) The extreme difficulty of carrying it into successful operation. (2) Its supposed effect in irritating, degrading, and even brutalising the minds of prisoners, by its vexatious discipline. They appeal in support of this position to the quantity of punishment (corporeal, or by solitary confinement) which is required to carry it into effect. 5. With respect to the introduction of *labour* into prisons of punishment, the chief question seems to be, whether it ought to form part of the punishment, and be of a vexatious and severe nature; or whether it should be used as an alleviation to the rigour of separate confinement and preparation of the criminal for re-entrance into society. The former is the principle commonly adopted in England; the ordinary sentence, for many offences, being imprisonment with *hard* labour, and with occasional intervals of solitary confinement; the treadwheel being the most common species of labour. On this subject the reader may consult the *original* article 'Prisons' in the *Ency. Brit.*; but the views of the author are somewhat too dogmatically expressed. The policy and practicability of making prison labour pay or contribute largely towards the maintenance of the prison has not been much discussed in England, where, from our less economical habits, the experiment has hardly been tried. In America several, it is said, afford a revenue to the state. (De Tocqueville, *Du Système Pénitentiaire aux États-Unis.*) In Belgium they have long been rendered very productive; the works of the present very able inspector-general, M. Ducpétiaux, contain ample information on the subject. It appears also, from various reports of the Irish prison inspectors, that the cost of work has been from time to time more than repaid by the return in every prison; but it does not appear clearly what is comprehended under the former head, and the numbers seem not altogether accurate.

By the Act 2 & 3 Vict. c. 56, *separate* confinement was for the first time distinguished from the severer punishment of *solitary* confinement, and the justices were empowered to make rules for classification, &c., subject to the approval of the secretary of state.

The discontinuance of transportation, except to a very limited extent in 1853, and the substitution of the punishment of *penal servitude*, made prison discipline a matter of even more importance than it had previously been. The result of observation of the *separate system* in the *model prison* at Pentonville ended in its being reduced to nine months for men and a year for women (1854), except in cases of short sentences of one or two years, it being held that the whole of a *short* imprisonment might be beneficially passed in this manner. The labour of prisoners has been devoted, as far as practicable, to the construction of public works. In 1857, after much oscillation of opinion, the principle of remitting part of the sentence for good behaviour was adopted by government: a scale of remissions being introduced in proportion to the length of the sentence. The Irish system of convict discipline is said to go further in the direction of relaxation than the English, 'bringing the convicts nearer to the condition of free citizens.' For the latest discussions on this subject, see the Evidence appended to the Report on Secondary Punishments of the Commission of 1864; and for the system designed to effect the amendment of the juvenile criminal population in separate establishments, see REFORMATORY.

Prisons, Mamertine. Places of confinement in ancient Rome, chiefly intended for state prisoners. They were constructed of large uncemented stones; and, from the specimens of them which remain, it is difficult to imagine a more horrible place for the confinement of a human being. There were two apartments, one above the other, to which

there was no entrance except by a small aperture in the upper roof; and a similar hole in the upper floor led to the cell below, there being no staircase to either. The upper prison was 27 feet long by 20 wide, and the lower, which was elliptical, was 20 by 10; the height of the former was 14 feet, of the latter 7.

Pristis (Gr. πρίστης). The sawfish. The common species of this genus of sharks (*Pristis Antiquorum*, Linn.) bears a process developed from the premaxillary, which measures one-third of the length of the body, and has on each side from twenty to thirty elongated conical teeth. The fish itself is often from twelve to fourteen feet in length.

Privateer. A vessel belonging to one or more private individuals, sailing with a license from a belligerent government, in time of war, to seize and plunder the ships of the enemy. It is obviously an abuse for the vessels of a neutral community to be so employed. But whether the vessel of a neutral state, armed with a commission from a belligerent, can be treated as a pirate, seems as yet an undecided question in the law of nations. (Phillimore's *International Law*, vol. i.) The practice of granting commissions to privateers first became general in the war between Spain and the revolted Netherlands, at the end of the sixteenth century; when it was extensively made use of by the prince of Orange as a means of annoying the Spanish trade.

By the treaty of Paris, in 1856, privateering was abolished as between the principal European nations. Whether, however, this abolition would hold good in actual war may reasonably be doubted, for privateering is the natural resource of a weak power against a superior adversary possessing a wealthy commercial marine. [MARQUE, LETTER OF.]

Privet (altered from prymet, *the primrose*, through a confusion between this flower and the shrub, to both of which the mediæval writers applied the Latin name ligustrum: Prior). The name of a common garden shrub, referred by botanists to the genus *Ligustrum*. The Common Privet, *P. vulgare*, is very frequently used for making dwarf hedges. The berries yield a black dye, used in preparing kid-skins for gloves.

Privilege (Lat. privilegium: defined by Cicero, lex privato homini irrogata). In the ordinary acceptation of the word, a law, or an exception from the common provisions of law, in favour of an individual or a body. Privilege is said to be personal or real; i. e. attached to the person only, or to the person in respect of a particular place; as to a member of one of the universities, an officer of one of the courts at Westminster. The privileges chiefly recognised by the English law are privilege of parliament [PARLIAMENT], and the privilege from arrest allowed to counsel, attorneys, and witnesses attending the courts of justice.

Privity. In Law, a peculiar mutual relation which subsists between individuals connected in various ways; so that, besides those who are actually parties to a transaction, others connected with these parties are said to be privy to the transaction, and are bound by its consequences. Several sorts of privity are enumerated by writers on law; but those of most ordinary occurrence are three: privity of blood, of estate, and of contract. The former subsists between an ancestor and his heir: the second between lessor and lessee, tenant for life and reversioner created by the same instrument; and privity of contract between those who are parties to a contract, which species of privity is personal only.

Privy Chamber, Gentlemen of the. Officers of the king's household, instituted by Henry VII. Their duties are to attend the sovereign; but the appointment is now merely honorary. There are also four gentlemen ushers of the privy chamber, whose office is to wait in the presence chamber, attend on the king's person, and note affairs under the lord chamberlain and vice-chamberlain.

Privy Council. [COUNCIL, PRIVY.]

Privy Seal, Lord. The fifth great officer of state in England, who has the custody of the privy seal of the king, used for all grants, charters, pardons, &c. before they come to the great seal. For the present practice, see SEAL.

Prize (Fr. prise, *a booty*). In International Law, anything captured by a belligerent using the right of war; in common language, only ships thus captured, with the property taken in them, and booty taken by an army, are so called. Prizes taken in war are condemned by the proper judicature in the courts of the captors: such condemnation is held to divest the title of the proprietor and to confer a new ownership. In order to give jurisdiction to a court of prize, it is deemed necessary, by the law of nations, that the property captured should be in possession of the captors in their own ports, those of an ally, or of a neutral; but no belligerent power has a right to capture in the ports of a neutral country, or within a marine league of her shores. Subject to capture are hostile property, i. e. the property of persons domiciled in a hostile country, and neutral property contraband of war. [CONTRABAND.]

The Prize Court in England is constituted by a commission addressed to the Judge of the Court of Admiralty [ADMIRALTY], the jurisdiction of which as respects naval prize has been recently defined and remodelled by the Naval Prize Act, 1864. Questions relating to *booty of war*, i. e. prize taken by land forces, are occasionally referred by the crown to the same court.

Prize Money. The proceeds of a prize on its sale. The money is divided among the captors in specified proportions, according to rank. In the case of a ship-of-war captured from a foreign power and adopted into the navy of the capturing nation, an allowance per gun is made as prize money to the captors.

Pro Re Natâ (Lat. *as occasion may require*). A term commonly used in medical prescriptions.

Pro-Hessian. The homogeneous equation of a developable of the n^{th} order contains a quaternary n-*ic* whose Hessian is of the order $4(n-2)$ in the variables. Now every point of a developable being a parabolic point reduces the Hessian to zero, so that the latter contains the original n-*ic* as a factor. The remaining factor of the order $3n-8$ is called the *pro-Hessian*. [DEVELOPABLE SURFACE; HESSIAN.]

Proa, Flying. A narrow canoe, about thirty feet long by three feet wide, used in the Ladrone Islands. The lee side is flat, being the mere longitudinal section of the common form, and the head and stern exactly alike. A slight framework projects several feet to windward, bearing a small block of wood like a canoe: this float supports the vessel from oversetting to leeward, as she would otherwise do, and the framework affords support for a weight acting against the pressure of the sail. The vessel is steered by a paddle at either end, and moves with great velocity, either backwards or forwards, being adapted to a side wind in running between two places. The sail is mat, with a boom, upon one mast. *Proa* is also the name for large boats used by the Malays, propelled both by oars and sails.

Proaulion (Gr. from πρό, and αὐλή, *a hall*). In Ancient Architecture, the same as a VESTIBULE.

Probabilism (Lat. probabilis, *likely*). In Theology and Ethics, a theory professed by some casuistical divines, chiefly of the Jesuit order, according to which it is lawful to follow a *probable* opinion in doubtful points, although other opinions may seem to the mind of the enquirer more probable. Those who teach this doctrine are styled *Probabilists*. This and the other tenets of the once celebrated science of casuistry are ably touched on by Mr. Hallam, in his *Literature of Europe* (pt. iii. ch. iv. § 13).

Probability, Theory of. A very extensive and important application of analysis, having for its object the determination of the number of ways in which a future or uncertain event may happen or fail, in order that we may be enabled to judge whether the *chances* of its happening or failing are the greater, and in what proportion.

In this theory the word *chance* is used to signify the occurrence of an event in a particular way, when there exist two or more ways by which it may take place, and no reason can be assigned for its happening in one way rather than another. In ordinary language, when an event is said to happen by chance, it is merely implied that the cause is unknown, or cannot be certainly appreciated.

The term *probable*, in its common acceptation, is applied to any contingent or future event, to denote that in our judgment the event is more likely to happen than not to happen. In mathematical language *probability* has a definite signification, and, if all chances are considered equal, it is measured by a fraction, the numerator of which expresses the number of chances favourable to the occurrence of the event, and the denominator the whole number of chances favourable and unfavourable.

Every contingent event gives rise to two opposite probabilities: one, that the event will happen; the other, that it will not; and the sum of these probabilities, which necessarily amounts to certainty, is always equal to unity.

Hence if p denote the probability of the occurrence of an event, the probability that it will not occur is $1-p$.

The probability of the simultaneous occurrence of several independent events is obtained by multiplying together their separate probabilities. Thus, let p denote the probability of an event A, q that of an event B, r that of an event C, &c.; then the probability of the joint occurrence of those events is expressed by the continued product $p\,q\,r$, &c.

The probability of the successive recurrence of the same event or of different events is determined in a similar manner. Thus, suppose m to be the number of white balls in an urn, and $n=$ the number of black balls in the same urn, and that when a ball has been drawn it is immediately replaced in the urn, so that at each trial the whole number of chances is $m+n$. Let $p=$ the probability of drawing a white ball on any trial, and $q=$ the probability of drawing a black ball; we have then

$$p=\frac{m}{m+n},\ \text{and}\ q=\frac{n}{m+n}.$$

And first let us consider the probabilities of the different possible events that may happen on two trials.

The only possible ways in which the balls can be drawn in two successive trials are these four:—

1. First white, second white; probability $=p\times p=p^2$;
2. First white, second black; probability $=p\times q=p\,q$;
3. First black, second white; probability $=q\times p=p\,q$;
4. First black, second black; probability $=q\times q=q^2$.

Adding together these probabilities, we get

$$p^2+2\,pq+q^2=(p+q)^2,$$

and the sum is equal to unity, as will be evident by substituting for p and q their values in terms of m and n.

It thus appears that the probabilities of all the different combinations that can be formed in two trials are respectively given by the developement of the binomial $(p+q)^2$. It will be observed that the term $2\,p\,q$ gives the probability of drawing a ball of each colour in the two trials without distinction of order; i. e. the white ball may be drawn either at the first or second trial.

Now, let the number of trials, instead of being two, be increased to any number u; the probabilities of the different combinations will be given by the developement of the binomial $(p+q)^u$. This developement is

$$p+\frac{u}{1}\ {}^{u-1}\,q+\frac{u(u-1)}{1.2}\,p^{u-2}\,q^2\ \ldots\ldots$$

$$+\frac{u(u-1)\,(u-2)\ \ldots\ (u-v+1)}{1\ .\ 2\ .\ 3\ \ \ \ldots\ \ \ v}\,p^{u-v}q^v+\text{\&c.}$$

The first term p^u indicates the probability of drawing a white ball in each of the u trials, or that all the balls drawn will be white. The second term $u p^{u-1} q$ denotes the probability of drawing $u-1$ white balls and one black ball in u trials without regard to the order; i. e. the black ball may be drawn at the first, second, third, or any other trial. The general term

$$\frac{u(u-1)(u-2)\ \ldots\ (u-v+1)}{1\ .\ 2\ .\ 3\ \ldots\ v} p^{u-v} q^v$$

gives the probability that in u trials $u-v$ white balls will be drawn, and v black balls, without distinction of order. If the probability of drawing the ball in a determinate order of succession were required; for instance, if it were required to determine the probability of drawing $u-v$ white balls successively, and then v black balls; the coefficient of the term must be suppressed, and the probability becomes $p^{u-v} q^v$.

The practical question most frequently arising is, not to determine the probability of the repetitions of an event in any precise order, but the probability that the number of repetitions will exceed or not exceed a certain limit. Thus, in the preceding example, suppose it were required to assign the probability that not fewer than $u-v$ white balls will be drawn in u trials; it is evident that as the first term gives the probability of drawing u white balls, the second term that of drawing $u-1$ white balls, and so on, and as each of these combinations satisfies the condition, the required probability will be found by taking the sum of all the terms of the developement of $(p+q)^u$ from the first to that in which the factor $p^{u-v} q^v$ appears, both inclusive.

In what precedes it has been supposed that the number of ways in which an event can arrive are known à priori; but it may happen, and indeed does happen, in the greater number of the most important questions to which the calculus of probabilities is applied, that the number of chances favourable and unfavourable to the occurrence of any particular event is unknown, and that the ratio of the one to the other can be inferred only from considering the ways in which the event has been observed already to happen. For instance, we may suppose an urn to contain a certain number of balls of different colours, the number of each colour being unknown, and that, from having observed the result of several trials, we have to determine the probability of drawing a ball of a particular colour at the next trial. The general method of proceeding in such cases is as follows: Let c, c', c'', c''', &c. be so many independent causes (or hypotheses), each of which may give rise to an event E; and let the probabilities of the existence of these causes be respectively h, h', h'', h''', &c., and those of the events calculated according to each hypothesis p, p', p'', p''', &c.: then the probability of the event E is $hp + h'p' + h''p'' + h'''p''' +$ &c.

The preceding examples will suffice to give some idea of the manner in which the probability of the occurrence or failure of events depending on chance is submitted to numerical estimation; but for the methods of applying the calculus in particular cases, and especially when the formulæ involve high numbers and the ordinary processes of arithmetic become unavailable, reference must be made to works specially devoted to the subject, a list of which is given at the end of this article.

The calculus of probabilities had its origin in the speculations of Pascal, Fermat, Huygens, and other eminent mathematicians of the seventeenth century. It was first applied to the solution of questions connected with games of chance; but it has since, by the researches of James Bernoulli, Montmort, De Moivre, D'Alembert, Simpson, Condorcet, Lagrange, La Place, Poisson, and others, become one of the most interesting branches of mathematics, and has been applied with equal success and advantage to numerous important questions belonging to natural and political philosophy. One of its most familiar and useful applications is to the subject of annuities, assurances, reversions, and other interests depending on the average duration of human life, and the expectation of the continuance or survivorship of lives of given ages. [ANNUITY; EXPECTATION OF LIFE; MORTALITY, LAW OF.] Another important application is to determine the most probable *mean*, or average, of a great number of observations; and hence its utility in many cases of practical astronomy and general physics. [PROBABLE ERROR.] Condorcet has applied it to determine the value of testimony, the verdicts of juries, and the best mode of constituting tribunals, and of collecting votes in elections. In such applications, it is true, assumptions more or less arbitrary must be admitted, and great uncertainty will always attach to results which are influenced by human will or caprice; nevertheless, the knowledge derived from an accurate and systematic analysis of the circumstances concerned, and of the consequences of their various combinations, affords important aid in guiding our judgments, and may be of great use in the practical affairs of life.

The following are the principal works on the subject: Montmort, *Analyse des Jeux de Hasard* (1st edit. 1708; 2nd, 1713); Bernoulli, *Ars Conjectandi*, 1713; De Moivre, *Doctrine of Chances* (1st edit. 1718; 3rd, greatly enlarged, 1785); Simpson, *Laws of Chance*, 1740; Condorcet, *Essai sur l'Application de l'Analyse à la Probabilité des Décisions rendues à la Pluralité des Voix*, 1785; La Place, *Théorie Analytique des Probabilités*, 3rd edit. 1820; Poisson, *Recherches sur la Probabilités des Jugemens*, 1837; the article in the *Ency. Metrop.* by Professor de Morgan, and that in the *Ency. Brit.* by Mr. Galloway (which is published separately). For elementary works, the reader may be referred to Simpson's *Laws of Chance*, and Lacroix's *Traité Élémentaire*, &c.; and for an explanation of the objects and results of the science, without mathematical investigation, to

Professor de Morgan's 'Essay on Probabilities, and on their Application to Life Contingencies and Insurance Offices,' in the *Cabinet Cyclopedia.*

Probable Error. In Astronomy and Physics, when the value of any quantity or element, as the declination of a star, the latitude of a place, the specific gravity of a body, &c., has been determined by means of a number of independent observations, each liable to a small amount of error, the determination (in whatever way it may have been deduced from the observations) will also be liable to some uncertainty; and the *probable error* is the quantity which is such that there is the same probability of the difference between the determination and the true absolute value of the thing to be determined exceeding or falling short of it. Thus, if twenty measurements of an angle have been made with the theodolite, and the arithmetical mean or average of the whole gives 50° 27′ 13″; and if it be an equal wager that the error of this result (either in excess or defect) is less than 2 seconds, or greater than 2 seconds, then the probable error of the determination is 2 seconds. The method of computing the probable error, which is deduced from the theory of probability, is as follows: Let l, l', l'', &c. be the *observed* values, h the number of observations, m the average value (i.e. the sum of the observed values divided by number of observations); then if we call $l-m$ the error of the observation l, and $\Sigma(l-m)^2$ the sum of the squares of the errors of all the observations, the probable error is

$$\cdot 674489 \times \frac{\sqrt{\Sigma(l-m)^2}}{h};$$

i.e. the square root of the sum of the squares of the errors, divided by the number of observations, and multiplied by the decimal ·674489.

It is frequently convenient to compute the probable error of a result from another function, which is called the *weight.* The weight is the square of the number of observations divided by twice the sum of the squares of the errors; and the probable error is ·476936 divided by the square root of the weight. This definition agrees with the former, for

$$\cdot 674489 = \cdot 476936 \times \sqrt{2}.$$

Probang. A flexible piece of whalebone with a ball of sponge attached to its extremity, used for the purpose of removing obstructions in the œsophagus.

Probate of a Will. In Law, the exhibiting a will before the proper court by the executor, and obtaining a *proved* copy thereof, is termed obtaining *probate.* The present Court of Probate was established in 1857 (20 & 21 Vict. c. 77), with jurisdiction to grant letters of administration of the effects of persons dying intestate, and probate of the wills of testators; the powers of the ecclesiastical courts in these matters being abolished. The court is presided over by a single judge, from whom an appeal lies direct to the House of Lords; so far as personal property is concerned, it has exclusive jurisdiction in all questions relating to the competence of a testator or the due execution of his will. The probate copy of a will forms the authoritative instrument on which the executors act, the original will being retained in the registry of the court, where an official copy of it may be inspected by any person on payment of a fee of one shilling.

Probe (Lat. probo, *I try*). A surgical instrument, generally made of silver wire, rounded at one end and pointed at the other, used for the purpose of examining wounds.

Problem (Gr. πρόβλημα). In Geometry, a proposition requiring some operation to be performed or construction to be executed; such as to bisect a line, to describe a circle passing through three given points.

Proboscidians. The name of a family of Pachydermatous Mammals, including those which have the nose prolonged into a prehensile trunk or PROBOSCIS; as the elephant and mastodon.

Proboscis (Gr. προβοσκίς, from βόσκω, *I feed*). In Entomology, the oral instrument of the Diptera is so called, in which the ordinary trophi are replaced by an exarticulate sheath, terminated by a pair of tumid lobes (labella), and containing one or more lancet-shaped instruments (scapella), covered by a valve.

PROBOSCIS. In Malacology, this term is applied to the tongue of certain Gastropods, when it is so long as to be capable of being protruded for some distance from the mouth; in which case it is generally organised at the extremity for the purpose of boring the shells of other testacea, and of destroying by suction the soft parts of the inhabitant.

PROBOSCIS. In Mammalogy, the prehensile organ formed by a prolongation of the nose, of which the trunk of the elephant is an example.

Procedendo or **Procedendo in Loquelâ.** In Law, a writ which lies where an action has been removed from an inferior to a superior jurisdiction on insufficient grounds, to send the cause back to the inferior court for further proceeding.

Procedendo ad Judicium. A writ which issues out of the Court of Chancery, commanding inferior courts to proceed to judgment where it has been unjustly delayed. This is practically superseded by the writ of mandamus from the Queen's Bench.

Procellariæ (Lat. procella, *a storm*). A Linnæan genus of web-footed birds, now the type of a family of the *Longipennate Palmipedes* in the system of Cuvier, characterised by the beak being hooked at the tip, with its extremity appearing as though a piece had been articulated to the rest; the nostrils are united to form a tube, which lies along the back of the upper mandible; and their feet, instead of a back toe, have merely a claw implanted in the heel. Those species in which the lower

mandible is truncated belong to the true *Procellariæ*. Some smaller species, with a shorter bill, rather longer legs, and black plumage, commonly called *Storm-birds*, or *Mother Carey's chickens*, are associated under the generic name *Thalassidroma*. The *Procellariæ* range over the high seas at the greatest distance from land. Their name of *Petrel*, which is a diminutive of *Peter*, has been applied to them from their habit of walking on the waves, which they appear to do with the assistance of their wings.

Procès-Verbal. In the language of French Jurisprudence, an authentic written minute or report of an official act or proceeding, or statement of acts. The term is also used to signify minutes drawn up by a secretary or other officer of the proceedings of an assembly.

Process. In the language of English Common Law, this term is used in two senses, to signify (1) the whole proceedings in an action or prosecution; and (2) the means whereby the defendant in an action is compelled to appear in court. When actions were commenced by original writ, original *process* was that which was founded on that writ, commencing with notice, writ of attachment, &c. *Mesne*, or intermediate process, was, properly speaking, such process as issued pending the writ on some collateral or interlocutory matter; as to summon juries or witnesses. But in popular language it was taken to signify the whole process, from the commencement of the suit, before the final process which ended it. Thus a defendant was said to be arrested on *mesne* process, i.e. on a writ of capias issued *pending* the suit. This was done originally when the defendant, being summoned, or attached, neglected to appear or made default. In course of time, by a legal fiction the summons and neglect were supposed; and the writ of capias became the commencement of the proceedings, to which the term *mesne process* was still inaccurately applied. The term *mesne process* is now commonly applied to the writ of summons, which is the instrument now in use for commencing personal actions. Thus the popular inaccuracy of language is retained. *Final* process is the writ of execution used to carry the judgment into effect. In ordinary language, the regular proceedings of every court of judicature in a suit are called its *process*.

Proclamation (Lat. proclamatio, *a calling out*). Public notice given by the king to his subjects. [KING; PRIVY COUNCIL.] The power of issuing proclamations is a branch of the king's prerogative, and vested in him alone. They have a binding force on the subject, in so far as they are grounded on and enforce the laws of the realm. They may be said to be of two sorts: the one, enforcing an actually existing law by giving it a particular application of time, place, and circumstance; the other, exercising an extraordinary power vested in the king, which until so exercised is dormant; as a proclamation to prohibit any subject from leaving the realm during a certain time. Proclamations must be under the great seal. By 31 Hen. VIII. c. 8 it was enacted that the king's proclamations should have the force of law: an enactment which, while it subsisted, did, in effect, make a complete revolution in the government of this country. It was, however, repealed five years afterwards by 1 Edw. VI. c. 12. Nevertheless, in later times, it was held by crown lawyers, that the king might suspend or dispense with an existing law in favour of particular circumstances. But by 1 Wm. & Mary stat. 2 c. 2 it is declared that no such power exists.

Procœlian (Gr. πρό, *before*; κοῖλος, *hollow*). In Anatomy, those vertebræ are so called which have a cavity or cup at the fore part of the body, and a ball at the back part. The term is also applied to a group of animals—e.g. a certain family of reptiles which manifest this vertebral character. It is found in most existing Saurians, but not in any extinct terrestrial species of earlier date than the Wealden period. The oolitic Pterodactyls were procœlian.

Proconsul. Originally an officer invested with consular command without the office. Thus, a consul sometimes had his command prolonged to him after his year of magistracy had ceased, with the title of *proconsul*. The provinces which at first were governed by prætors were, for the most part, subsequently put under *proconsuls* and *proprætors*, who were at first especially appointed at the Comitia Tributa; but afterwards, by the Sempronian law, they entered on their provincial jurisdictions forthwith, on the expiration of their year of consulship or prætorship. The office was properly annual; but it might be prolonged, as was done in the case of Cæsar. In the time of the republic the proconsul held the military command as well as the civil jurisdiction of his province, and accordingly had about him a large staff of officers, as the lieutenants or legati, præfects, &c. But Augustus, on assuming the chief power in the state, remodelled the system by a new partition of the provinces, and by separating the civil jurisdiction, which was left to the proconsul, from the military command. Under the emperors, the proconsuls and proprætors were distinguished by the former being appointed to the provinces under the especial superintendence of the senate; the latter, with the title of *legati Cæsaris*, to those which the emperor held.

Procris (Gr.). This beautiful creation of mythical speech is described in the Athenian tale as a daughter of Erechtheus; but in unconscious fidelity to the old phrase her mother is still Hersê, the dew. In the spring time of her youth, she wins the love of Kephalos (Cephalus), a chieftain of Phokis (Phocis), who is also loved by Eos. By the persuasion of the latter, Kephalos is at last tempted to try the constancy of Procris; he therefore leaves her, and after a while coming to her again in disguise, succeeds in gaining her affection.

On discovering her shame, Procris flies to Crete, where Artemis gives her the spear that never misses its mark, with the hound which attended her in the chase. These gifts are coveted by Kephalos, to whom Procris (disguised in her turn) refuses to give them except in exchange for his love. They are thus reunited; but the unerring spear in the hand of Kephalos soon smites Procris, who was hidden by the thick bushes; and Kephalos, journeying westwards, in his sorrow, reaches the Leucadian cape, whence he sinks into the sea. This beautiful legend shows beneath a veil almost transparent the loves of the sun and the dew. Kephalos is the *head* of the sun; while the name Procris is explained by a reference to the Sanscrit *prush* and *prish*, to sprinkle, and thus the myth resolves itself into a few simple phrases. Kephalos loves Procris, as the sun loves the dew; but Eos also loves Kephalos, as the dawn loves the sun. Procris is faithless, yet she gives her love to the same Kephalos, as the sun shines reflected from the various dewdrops. Procris lastly is killed by Kephalos, as the dew is absorbed by the sun. For a further analysis of the myth, see Max Müller, *Comparative Mythology*, 54; and Cox, *Gods and Heroes*, 49 &c.

Procrustes (Gr. προκρούστης, *the stretcher*). In Greek Mythology, a surname for the robber Polypemon or Damastes, who placed his victims on a bed which was either too small or too large, and to the size of which he adapted their limbs by force. He was slain by THESEUS.

Proctor (Lat. procurator). In Ecclesiastical Law, he who undertakes for his fee to manage a cause in the ECCLESIASTICAL COURT.

In the English Universities, both at Oxford and Cambridge, two masters of arts are appointed annually to the office of proctor. Each college, in both (and at Oxford the halls collectively), nominates a proctor in rotation according to a cycle of years drawn up on mathematical principles, the basis of the calculation being the average number of masters of arts on the books of each society. The proctors are officers of considerable importance; being, in the first place, the chief police magistrates for the time being of each university. With their deputies the pro-proctors, they have not only power to enforce the rules of academical discipline on the students, but also an extensive summary authority over the townspeople, according to the special privileges of the universities. They also have, in both universities, peculiar legislative authority as assistants to the heads of houses, and official votes in the election of many professors and other officers. The proctors must be masters of arts, and their standing as such, at Oxford, from four to fifteen years. Originally the functions of the proctor in the universities consisted in the management of academical funds, both those collected by the bedels from all members of the university, and those which were derived from estates either possessed by the university in its own right, or held in trust by the university for particular corporations. Hence, conjointly with the chancellor, they kept the keys of the academical treasury, and their formal admission to office was accompanied by the delivery of these keys. One of these treasure chests is preserved in the picture gallery of the Bodleian Library at Oxford, and is fastened by a lock which springs twelve or fourteen bolts, the key of which was in the custody of the chancellor, and by two padlocks, the two keys of which were kept by the two proctors. The exercise of academical discipline by these officials is of comparatively late date.

As the universities discouraged the study of the common law, and adopted the rules of the civil code, in their local jurisdiction, they styled the advocates who were empowered to plead in their courts by this name also. Such persons were called proctors *ad lites*, their chief function being that of suing out process for debts. Till within the last few years, this office was filled at Oxford by masters of arts, but by a late change attorneys at law are admissible to practice, on nomination from the vice-chancellor.

The representatives of the clergy in Convocation are also called *proctors*, because they were intrusted with the assessment of taxes granted by that body. Originally, the proctors in Convocation received wages, as did the knights of the shire and the burgesses of parliamentary towns.

Procurator (Lat. pro, *for*, and cura, *care*). A Roman provincial magistrate, whose office it was to manage the affairs of the revenue, and exercise a judicial authority in matters pertaining to it. Sometimes the procurator discharged the office of governor, especially in a small province, as did Pontius Pilate in Judæa; in which case, but not otherwise, he had the power of inflicting capital punishment. This magistracy did not exist under the republic, its duties being comprised under those of the prætor or proconsul. Under the emperors these magistrates were called *procuratores Cæsaris*, to distinguish them from the common procurator, who was merely an agent employed by private persons to manage their affairs in their absence when an action was brought against them.

PROCURATOR, PROCUREUR, &c. In the Civil Jurisprudence, one who undertakes the care of any legal proceeding for another, and stands in his place by virtue of a power of *procuration* from him. A *mandatory* is said to differ from a *procurator* in that the latter acts only by virtue of an express written instrument. In France, before the Revolution, the procureurs (procuratores ad lites) were officers legally empowered to carry on suits on behalf of clients. This body was abolished in 1791, and that of *avoués* substituted in its place. The *procureurs du roi* in France are officers of whom one is appointed to every tribunal of arrondissement, together with a sufficient number of *substitutes*.

Procurator Fiscal. The title of the public prosecutor in the inferior courts of Scotland. The procurator fiscal, who usually makes the preliminary enquiries as to crimes committed in his district, acts under the lord advocate, who is the principal public prosecutor.

Procureur-Général. The public advocate of the crown in France. Every *parlement* or *cour souveraine* had, before the Revolution, a *procureur-général* attached to it. Under the present system of judicature, one of these officers is established in every *cour royale*, for the criminal part of its proceedings: and under him an *avocat-général*, for the civil department of the court. The public accusers in the inferior courts of assize and *première instance*, are termed respectively *procureurs criminels* and *procureurs d'état*. These officers are charged with the conduct of all criminal proceedings on behalf of the prosecution; and are placed under the immediate control of the minister of justice.

Procyon (Gr. προκύων). In Astronomy, the name given to the brightest star in the constellation of *Canis minor*.

Procyon. In Zoology, a genus of Plantigrade Carnivorous mammalia, of which the common racoon (*Procyon lotor*) is the most notable species.

Prodigy (Lat. prodigium). In ordinary modern language, this word signifies a surprising though natural event; in contradistinction to *miracle*, which denotes something out of the course of nature. Among the Romans, however, any extraordinary event or appearance, to which, from insufficient acquaintance with natural history, they could not assign a cause, was termed a *prodigy*, and regarded as indicating the dispositions of their gods. Hence the number of recorded prodigies which occur in Roman history. [Omens.]

Prodomus (Gr. πρόδομος). In Ancient Architecture, the portico before the entrance of the cella of a temple; the same as *pronaos*. [Naos.]

Produce, Raw. A formula used in Political Economy in a somewhat more limited sense than *raw material*. Thus, sugar, corn, cotton, are called *raw produce*, while ores, timber, dye, &c. would be *raw material*. In the latter case, little or no labour has been expended on the article beyond that which is necessary in order to appropriate it; in the former, some, and often great, labour has been laid out in the cultivation of the article. No precise line, however, can be drawn between the proper use of either term. [Material, Raw.]

Product (Lat. productus, *brought forward*). In Arithmetic and Algebra, the result of, or quantity produced by, the multiplication of one number by another, or a quantity of any kind by a number. [Multiplication.]

Producta (Lat.). An extinct genus of fossil bivalve shells, closely allied to the living genus *Terebratula*. They only occur in the older secondary rocks.

Production (Lat. productio, from produco, *I lead forward*). In Political Economy, the process by which the labour either directly applied by man, or indirectly (i. e. in the guidance given by labour to the muscular powers of animals), and the mechanical powers of certain physical objects, as steam, wind, or running water, are made available for the developement of utilities from the materials and forces supplied by nature. As no labour is possessed of any economical significance unless it be exercised on articles possessing a value in exchanges, and destined to be exchanged, so all production which has an economical value is of commodities in demand. Similarly, a nation will not be stimulated to the production of any commodity beyond its own immediate or habitual wants, and therefore will not enter on any operations in exchange, unless it be offered some article which it desires and cannot produce, or cannot produce so easily and cheaply as other labour can. Thus, when after emancipation the negroes in the British West India islands, having only the lowest and most rudimentary tastes for the conveniences of civilisation, and possessing the means of gratifying them in abundance, were invited to produce commodities by their voluntary labour, the expectation that they would respond to the invitation was necessarily disappointed. But the extension of the desire for the higher class of utilities is a great stimulus to production; and the policy which discouraged, by means of sumptuary laws, any expenditure among the poorer classes of society beyond what was required for the bare necessaries of life, was not only an unwarrantable intrusion upon private liberty, but a great hindrance to economical progress. The neglect of the distinction between the use of the reasonable comforts and conveniences of life in the fullest measure that can be achieved consistently with prudence and economy, and the depraved taste for vicious indulgence, forms the fallacy of Mandeville's paradox that private vices are public benefits, in his fable of 'the bees or knaves turned honest.' On the other hand, mere expenditure is not production, nor a stimulus to production. When Louis XIV. answered Madame de Maintenon, on her requesting him to give alms to the people in a time of scarcity, that the best charity he could give was in spending money, the fallacy was equally irrational; he could only spend on luxury, by taking from poverty. Production in particular articles may be in excess, and in consequence the market price may fall below the cost of labour expended on the article; but there cannot be a general over-production, for this would only mean that everybody had more of everything with less labour. General over-production is, in fact, identical with the phrase *a general glut*, which is a contradiction in terms. [Glut.]

Production, Cost of. It is a fundamental position in Political Economy, that labour which has an economical significance is always undertaken with a view to profit or advantage.

The exchange of produce manufactured with such a purpose is determined by supply and demand, for both of these, if action be free and uncontrolled, are affected by the competition of buyers and sellers, or of production and exchange, the measure of both products being money. If, therefore, that which holds good between individuals affects communities also, the discovery of any means by which the cost of production may be lessened, gives an advantage in trade to the individual or the community which may possess the easier and less costly means of producing the commodity or commodities in which it trades. And as everyone is busied, economically speaking, in getting the largest advantage for the least labour, free action will always strive to diminish to the minimum amount the cost of production in the manufacture of all articles which are demanded and may be supplied, whatever be the form of industry adopted by a community, or presented to it by favourable conditions of soil, climate, and the like.

The two contributories to the cost of production are labour and profit. Rent does not diminish or increase the cost of production, but variations in the cost of production and in the demand for the produce increase and diminish rent. The interest of the landowner is not, therefore, except in a very indirect way, contrary to the interest of the public, as Ricardo thought; but the advantage of the public, and the general prosperity of all classes, is of the highest significance to the interest of the landowner, since it is by the demand for agricultural produce (not, as the authors and supporters of the old corn laws imagined, for grain only, but for all produce), that larger claims can be made for the use of such natural powers as the soil possesses. That rent does not increase the cost of production is manifest; for no one imagines that if all rents were extinguished, population and its demands for agricultural produce remaining the same, prices would fall. The only difference would be, that the whole of the difference between the cost of production and the price at which the produce was sold would become the advantage of the agriculturist; i.e. he would take not only the wages of his labour, the insurance on the risks of his occupation, and the profit of his capital, but indirectly the rent of land. Nor does this affect rent which is derived from land employed in tillage only; exactly the same circumstances belong to land let for building purposes, and occupied in thoroughfares or other localities particularly suitable for business. Rent obtained for such sites does not increase the expense of carrying on such a business, but the business is of such a character as to secure larger advantage to the occupier than could be obtained in a less favourable locality; and as far as this advantage is not due to the intelligence, capital, and labour of the trader, the landlord is enabled by the principle of competition to obtain a share of the commercial fertility of the site, just as he does of the natural fertility of a rich soil.

The cost of labour as affecting the cost of production is measured not necessarily by the wages of labour, but by its efficiency. Low wages may be economically dear, high wages may be economically cheap. The wages of domestic servants in India are very low; but if the aggregate of service obtained by a dozen natives does not equal the effectiveness of one European domestic, the cost of service may be much higher in that country than it is in England. Similarly, if the charge to which a contractor is put in hiring one kind of manual labour is one-half the rate at which another kind of labour may be hired, and the latter kind does treble the work of the former, the latter is cheap, the former dear. So, in a manufactory, the labour of children may be hired for three shillings a week, and that of some artisans employed may be as much as three pounds; but the result of the former kind of labour may not, and often does not, represent so large an advantage as that which is derived from the labour of the latter. It is even possible that a shorter time of labour at equal wages may be more advantageous to the employer, because the gross produce of the labour is larger, as its quality is better; and that which applies to human labour, applies equally to its substitutes. The old-fashioned English cart-horse might fifty years ago have been purchased for five pounds, and might have been kept at five shillings a week. A good modern cart-horse may cost fifty pounds, and require food valued at twelve shillings. But if the power of draught in the old cart-horse was equal only to ten tons, and that of the better bred animal to thirty, it is more economical to employ the latter labour than the former. So with machinery. A threshing machine may cost two hundred pounds; but if the produce of this substitution for human labour represents a gain of twenty per cent. on the old manual labour, it is better to buy or hire the machine than to continue the use of the flail. The same observations apply to reaping and ploughing machines, which can commend themselves to public notice and use only in the event of their performing the services done by manual labour with equal efficiency and at less aggregate cost.

In those countries where the real cost of labour is high, owing to the existence of large and easily procurable tracts of fertile land, and to the scantiness of population, the stimulus to the substitution of mechanical for manual labour is exceedingly strong, and the invention of machinery in aid of human labour is remarkably progressive. The United States have in effect produced many machines which in great degree supersede human labour, and in all cases multiply its efficiency. Such are the sewing machine in private life, and the various agricultural machines which have been adverted to. So great is the demand for such aids, and so abundant is the supply of these aids in substitution or multiplication of human labour in the United States, that, as the writer is informed, though the contribution of the state of Ohio to

the late war was not less than 90,000 males, out of a population of little above two millions, the labour of housing one of the largest harvests ever known in that state, that of 1864, was accomplished easily by the abundant use of agricultural machines. But where labour is cheap and population dense, the stimulant is less vigorous. This comparative indisposition to employ mechanical forces in aid of human labour is most manifest where, as in this country, a legal provision is made for the relief of the poor, the tenure of land is precarious, or at least the tenant is liable to the caprice of the landowner.

The rate of profit or interest has its effect on the cost of production, partly because the producer in so far as he is a capitalist will need to be satisfied by receiving, in the aggregate of what is called his profit, the ordinary rate of interest, partly because in many productive operations much capital is borrowed. If, therefore, the rate of interest is raised by any insecurity felt as to the repayment of the advance, industry is seriously hindered, and undertakings cannot be entered on, or not entered on with ease and safety. With high rates of interest, where the investment is secure and the sole cause of the high rate is the large competition for capital consequent on high rates of profit or advantage, the cost of production is indeed enhanced; but industrial occupations may be carried on with great energy, because wages and profits being high, the borrower receives his benefit in the large payment made for his industry and skill.

It would seem at first sight that a diminished cost of production, consequent on the substitution of mechanical for manual labour, would lower the rate of wages. It is notorious that no such result has ensued, notwithstanding the gradual increase of population in this country, and the considerable employment of these aids. Thus, for instance, one branch of agricultural labour has been almost entirely superseded; that, namely, of hand threshing. Where labour is far short of the demand for it, the possibility of a reduction in wages is remote; if, of course, only one kind of labour could be supplied by an individual, the total cessation of employment in this direction would induce great distress. But it rarely happens that labour, especially that which is dependent on those pursuits in which such results might be anticipated, is of so special and simple a character. The agricultural labourer performs many different functions, and the progress of agricultural science has rather added to than diminished their number by the substitution of machinery. Besides, almost all occupations (those, for instance, which supply machines for agricultural purposes) need a considerable amount of unskilled labour. The construction of railways, an operation as relevant to agricultural as to manufacturing pursuits, has absorbed a large amount of what may be called the surplus population of country districts, and the demand for labour in those regions which are peculiarly manufacturing has occupied many more, the late census indicating a notable decline in the purely agricultural counties. Nor does a diminished cost of production in one branch, or indeed in all branches of agricultural industry, diminish rent, provided the demand be fully commensurate with the increase effected. It must be remembered that an agriculturist is engaged in a large number of operations. It is possible, indeed necessary for the well-being of society in densely peopled countries, that the first necessaries of life should be supplied abundantly by importation from abroad; but it does not by any means follow that the gains of the agriculturist will be diminished, or the rent of the landowner lowered. Neither have been so affected, as we know by facts; the cause of this result, unexpected or disputed when it was only theoretically certain, is to be found in the fact that greater prosperity has given enlarged powers of purchase to the general public.

If a community is maintained, on an average of years, entirely upon the produce of its soil, the number of persons other than agriculturists which the country contains will denote the rate of production, or the cost of producing food. Similarly, if information can be procured as to the general rate of production from given areas at any period in the history of a community, during which no actual or no important supply of food has been introduced from a foreign country, the evidence so obtained will be a fair basis on which to conclude what was the population of a country, in the absence of any direct evidence derived from an enumeration or census. Now, there can be little doubt that the rate of production in this country, before the introduction of root crops, artificial grasses, and the improvement in the herds of horses, oxen, sheep, and pigs, was little if any more than one-twelfth of that which is at present obtained from the soil; and conversely it is certain that the whole population was regularly or occasionally occupied in agricultural pursuits. As measured by quantity, therefore, the cost of production was far greater in ancient or mediæval than in modern times; and similarly, the amount of the population must have been, it may be safely concluded, no more than an eighth of that which now inhabits England and Wales. Nor is this reasoning without its modern parallels. In the most fertile states of Western America, the rate of production is little more than from twelve to twenty bushels of wheat to the acre, the power of abundant export being derived from the large area of land available for cultivation, the ease and cheapness of transit, and the substitution of mechanical for manual labour. The increase in the rate of production and the diminution in the cost of production have not, therefore, it may be safely asserted, been derived from the necessity uniformly alleged in the ordinary theory of rent, that namely of increased expense incurred in the cultivation of inferior soils, but in the discovery and adaptation of forces in agricultural chemis-

try; in the study of practical physiology in the herds of animals, both of which means for cheapening the process have been developed to a remarkable degree; and in the application of mechanical force in aid or in substitution of human or manual labour.

The diminution in the cost of production in the supply of manufactured goods is still more notable; and the reader may be referred to Mr. Babbage's *Economy of Machinery and Manufacture* for information and illustration on this topic.

The question how far the cost of production is increased by the operation of trades' unions and the accompanying machinery of strikes, will be found below under the head TRADES' UNIONS. The reader may be referred to the same head for a statement of what appears to be the real incidence of such attempts to raise wages, as also to the articles COMBINATION, LABOUR, and WAGES.

Proedri (Gr. προέδροι). Certain Athenian officers chosen to superintend the proceedings in the two legislative assemblies; so called because they had the privilege of sitting in the front seats (προεδρία). The proedri of the senate were ten in number. [PRYTANES.] The proedri of the ecclesia were more in number, one being appointed from each tribe, which did not contain the prytanes for the time being. Their duties extended only to the one assembly of the people, a new set being elected each time; and one of their number was appointed EPISTATES or president. Their employment was to propose the subject of debate to the people, and to count the votes.

Proem (Gr. προοίμιον, *an opening*, from οἶμος, *a path*). A word sometimes used as synonymous with PREFACE or *introduction*. By the ancient Greeks it was used especially to denote a short hymn introductory to a longer poem.

Proemptosis (a word made up from Gr. πρό, *before*, ἐν, *in*, and πτῶσις, *a falling*). The term applied to the lunar equation or addition of a day to prevent the new moon happening too soon; this must be done every 330 years, and another day must be added every 2,400 years. The opposite term is *metemptosis*, which is used to signify the solar equation necessary to prevent the new moon from falling a day too late, or the suppression of the bissextile every 134 years.

Professor (Lat.). The recognised title, in all universities, of the public and authorised teachers in the various faculties. In the origin of those institutions the degrees conferred on students were, in fact, licenses to commence as public teachers; and the terms *master*, *doctor*, and *professor* seem to have been used indifferently. But as in process of time the great body of graduates ceased, in most universities, to have any concern in public instruction, a separate body of recognised teachers gradually arose; endowed in some instances with salaries, in others paid by fees. These were the professors. But in those universities in which collegiate foundations prevailed, as in Oxford and Cambridge, these officers fell into a secondary situation. The necessary business of instruction was transacted, and still continues to be so, by the functionaries of the several colleges. The professors therefore, and the instruction which they convey by lectures, have become only auxiliaries, instead of principals, and attendance on their lectures is in few cases compulsory. On the other hand, in universities destitute or nearly so of collegiate endowments (as those of Scotland, Germany, and others founded on the German model), the professors have become at once the governing body of the university, and the sole recognised functionaries for the purpose of education.

Profile (Fr. profil, Ital. profilo). In Architecture, the contour of the different parts of an elevation, whatever may be the style adopted.

PROFILE. In the Fine Arts, an outline of the principal parts of an object, free from all foreshortening, showing their real projections, indentations, &c.

PROFILE. In Fortification, a vertical section through a work, perpendicular to the face of the work.

Profit (Fr.; Ital. profitto, from Lat. profectus, *advantage*). In Political Economy, that rate of increase on capital with which the capitalist is so far satisfied as to constantly accumulate, either on the presumption that his capital will with moral certainty be repaid him in case he makes an advance to others, or on the conviction that his capital will be replaced in case he employs it for his own advantage. There is, therefore, no fundamental difference between the rate of interest and the rate of profit: the distinction lies only in the employment of the capital accumulated, for interest is always used to designate the profit on a loan, while profit is made to imply at once the recompense made for advances, and the addition made to capital employed by its possessor. It is, therefore, important to distinguish profit from wages, and to understand by wages not only payments made to labour, but all that part of a man's advantage from the employment of capital which is obtained by the fact that he devotes labour and skill to the occupation in which he is engaged, and by which (in case any risk attaches to his business) he secures himself such an increased remuneration as forms, so to speak, a species of insurance on his outlay; in other words, a capitalist must be paid for his trouble, as well as be rewarded for abstaining from spending his possessions on his personal enjoyment. Wages of labour in similar occupations tend to an equality; and, either consciously or unconsciously, everyone attempts to insure himself against risk. When, therefore, the labour is satisfied, and the risk is obviated, the remaining portion of the increase is profit; and as this remaining portion is on hypothesis secured to the capitalist as fully as the cost of the items which make up what is popularly called profit in business, it will not, and cannot be, more

than the rate of interest. Hence, when it is said that a small trader in a small town requires a large rate of profit on his transactions, while a great one is satisfied with less, no more is meant than that the wages of labour distributed over each sale, and perhaps the risks of his occupation, are necessarily larger, pro ratâ, than those of the trader whose business is more extensive, and thus it is that traders with large business can always offer goods to customers at lower rates than those whose occupations are circumscribed and whose market is narrow. The rate of interest on capital is the same, the remuneration of other elements is larger.

The *rate of profit* is the least sum which persons will accept as an inducement to accumulation. If the persons who possess property are thrifty and averse to spending, they will be, and constantly are, satisfied with low rates of profit. The Dutch were thus satisfied, though the low rate which they accepted was forced upon their trade by themselves, in consequence of their foolishly endeavouring to maintain high prices by checking or regulating supplies. This fact was overlooked by Adam Smith, who ascribed the low rate of profit prevailing in Holland before the close of the eighteenth century, to the heavy taxation to which the country was subject. But taxation may be heavy, and general profits high, or taxation may be low and general profits low, for the rate of profit is not necessarily connected with taxation at all, since taxation need not do more than curtail the power of enjoyment possessed by individuals. On the contrary, if the habits of society in any community are such as to make them indisposed towards saving when the rate of profit is materially lowered, accumulations will cease, or, what is more frequent, capital will be destroyed by investment in undertakings which are ultimately unproductive or scantily profitable. In short, it is hardly necessary to say that there are two sets of economical phenomena which are particularly liable to the stimulus of inconsiderate investment; that, namely, in which the rate of profit is apparently high, and that in which the rate of interest is temporarily very low.

Adam Smith held that the cause which led to a diminution in the rate of profit was the competition of capitals. We have seen above that he also considered it might be the effect of increased taxation, and have adverted to what appears to have been the real cause of the low rate to which he refers as a fact in the history of Dutch trade and finance. But, unfortunately, when he says that a competition of capitals lowers profit, he does not inform us of the way in which this result ensues. It cannot be by a general lowering of prices, because this would mean that everyone got more for less money, and so no one would be the worse. Nor can it mean that it occurs because a competition in one branch of business lowers what are called the profits of the business by lowering the price of the article consumed, since no one has recognised more clearly than Smith has, that there is, all other things being equal, a tendency to equal profit in all callings. It remains, then, that the competition of capitals lowers profits by raising wages. This appears to be the case in all avocations but that of agriculture, where a low rate of profit may prevail in consequence of the competition of farmers for the occupation of the soil, the price of labour being uniform, and the increased rent for the license of cultivation becoming the advantage of the landlord. Of course this specialty will not remain as a permanent characteristic of the demand for land capable of cultivation, since the competition of capitals will tend ultimately, other things being equal, to equal rates of profit in agriculture and commerce. But if capitals lower rates of profit by competition, it must needs be by the competition for employment; and as the employment of capital is the maintenance of labour, the reduction of the rate will imply, as a consequence from large accumulations of capital, a large payment to labour for services. In other words, capital is working investment, and the only form which the investment can really take, whatever may be the apparent direction, is in the maintenance of labour. If the capital be very large, the only means in which it can be employed is in the enlargement of wages. It need hardly be said that this competition may not lower prices; it may in effect, by the demand for the materials of production, considerably raise them in certain directions.

The direction which an accumulation of capital considerably in excess of the ordinary or general requirements of an existing community may take, will be either that of increased labour on the soil, or increased production for foreign trade. But it does not seem absolutely necessary, in order that larger products should be obtained from the soil, that lands hitherto not susceptible of cultivation, or not up to this time cultivated profitably, should be occupied and tilled. This will not be necessary till all the capital which can be employed is devoted to the better cultivation of areas already cultivated, but cultivated imperfectly. And this, in fact, is what has happened historically in this country. It is probable that in the more settled parts of England—excluding, for instance, the Scotch and Welsh marshes, as much land was under the plough five hundred years ago as at present. We may certainly argue hypothetically, from the case of all possible capital being applied to areas at present cultivated, that the practice of agricultural skill has by no means reached the limit of productiveness, since it certainly has not absorbed all the capital with which it may be supplied. By far the most powerful means, however, by which the reduction in the rate of profit may be averted, lies in the increase of production for foreign trade; and this has been the means by which the vast accumulations of capital in this country, and to some extent in other countries

also, have been made, and are employed without any notable reduction in the rate of profit or interest, but, on the contrary, are accompanied by certain phenomena which indicate a rise in the rate.

Political economists are apt, in interpreting the phenomena of wealth, to ignore, in some degree at least, the fact that the reciprocal relations of communities are rapidly modifying the conclusions which have been accepted from the various restrictions which the policy or fears of administrations have laid upon international intercourse. In fact, the inhabitants of civilised communities are getting more and more into the condition of members of the same economical state, denser populations representing towns and manufacturing districts, scantier ones the regions where agriculture prevails. From this point of view, the emigration of settlers is attended, only on a larger scale, by the same phenomena as the immigration into towns, and does not so much represent the relief of a redundant population, as the creation of facilities for the cheap production of food, which shall be exchanged against the manufacture of the more densely inhabited regions. In this way, the customs duties collected on foreign goods correspond to the octroi which is levied on consumable articles in towns; and the creation or improvement in the means of transit from country to country is analogous to the act of making a railway from a town to a rural district, between which localities there has hitherto been either imperfect communication or no communication at all. Just, too, as the produce of country districts could not be purchased, unless a town supplied commodities of its own manufacture or commodities imported by its labour in a carrying trade, so no intercourse will take place with distant countries except on the terms of mutual advantage. Now, the more widely this intercourse is extended, the more fully communities understand that they have mutual and inseparable interests of the very highest significance, and see that differences tending to war, and the cessation of intercourse between nations, vary only in degree from the folly and ferocity of civil war, the more distinctly public opinion is led to the true interpretation of national jealousies and narrow patriotism, as being a mask for the aggrandisement of administrative vanity, or for the satisfaction of personal spleen, at the expense of the general community; the more certainly all the speculations of political economists, as to the mininum rate of profit, the effect of taxation on public resources, the possible exhaustion of fertile soils, and the enhanced cost of cultivating inferior ones, become practically unimportant, because their contingency is made so exceedingly remote, and will have only a theoretical value, never to be of immediate interest except as consequent on the ultimate overcrowding of the human race on the whole surface of the earth. Up to this time, on the hypothesis of a larger and more complete understanding of what really constitutes the friendly intercourse of nations, the occurrence of a minimum rate of profit will be indefinitely postponed by investment in what are called indeed foreign undertakings, but which are in reality, when the undertaking is of an industrial character, means for cheapening articles sold in the home market; the process by which all fertile soils employed for raising food are exhausted, will in all probability be extended into a geological period; the effect of taxation (unless indeed, as is rarely the case, it be levied for industrial purposes) will be seen to be the destruction of capital, and the creation of an order of persons unfitted for industrial pursuits; and the wisdom of administrations will be directed towards effecting a closer unity and larger interdependence of all societies composing the civilised world, instead of being, as is commonly the case at present, an alternation of suspicion, timidity, military aggrandisement, and economical loss.

It is in consequence of the partial developement of these wiser and happier views as to the intercourse of nations, that the predictions of many economists have been falsified by events. The land of this country has not increased a square mile in the last five hundred years, it has probably decreased by the abrasion of the sea; the agricultural produce has, as we have elsewhere stated, increased twelve times, the manufacturing industry fifty-fold during the last two hundred years. But the rate of profit, as measured by the rate of interest, has not varied notably for the last hundred and fifty years, i. e. since the time that legal interest was fixed by the statute of Anne at five per cent. This uniformity is to be assigned partly to the enormous developement of the internal resources possessed by the country, and as much to the foreign trade developed by it; but that foreign trade has been rendered possible only by the growth of wealth among other nations, by the increase of their powers of production and purchase, and, as is attested by facts, by the rate of profit being sufficient not only to stimulate accumulation, but to develope those faculties of observation and research which have issued in such singular and prodigious discoveries in the materials and the powers of nature.

It will be seen that, in the account given of profit, the word has been treated as identical with interest on advances, the sole difference discoverable in the two terms consisting in the fact that interest is understood to mean the payment made for loans, profit the advantage derived from the employment of capital by its owner. There is, it appears, no reason for recognising any other difference in the two terms, any more than there is for distinguishing that portion of the produce of the soil which is paid as rent to a landlord, and that which is retained by the cultivator in excess of the receipts of the tenant farmer, when such a cultivator happens to be also the owner of the

soil. Commonly, however, just as rent is confounded with interest on capital and wages of labour when the same person is the recipient of all these, so profit is confounded with wages when the same individual is at once capitalist and labourer. There would be, indeed, no practical evil in such an error, but only a logical indistinctness, were it not that in this confusion of wages and profit a different criticism were customarily applied to different individuals or different classes. It will not be difficult to discover instances of such a confusion and such a criticism.

A combination to raise profits, if profit be understood to mean the interest on capital, or, as Adam Smith calls it, the profits on stock, will be wholly nugatory, just as all legal regulations affecting to limit rates of interest have been invariably inoperative and illusory. But a combination to raise wages under the name of profits is not only possible, but general. Where the use of the combination is adopted by the worker, for wages paid by a capitalist, the mechanism is open, and we call the association of labourers a trades' union; but where the body of capitalists unite to maintain prices, or to fix a standard below which professional etiquette will not permit a fee to be taken, the mechanism is secret, and the real significance is obscure. But in effect trade and professional regulations are of exactly the same nature as the combinations of workmen, assume the same line of defence, are open to the same regulation, and are virtually unions for the increase of wages, however much they may affect to be attempts to secure uniform rates of profit. In short, although competition will be found to determine interest, rent, and insurance, it will be found, on a careful examination of facts, to have only a limited operation in determining the rate of wages. Everyone can understand what is the meaning of the more violent attempts to increase wages by a monopoly, by a trades' union, or by legislative enactments which give one of two contracting parties a power to fix prices, by refusing the same discretion to the others; but there are many other invasions of the natural freedom of economical action, which would be justly interpreted by a sound and scientific exposition of the principles on which the mutual services of mankind should be appraised and exchanged. Among these none are more frequent than combinations to raise wages, under the name of profits, and few have done more to hinder the mass of consumers from receiving all the benefits of fiscal reform and free trade. [TAXATION; WAGES.]

Prognosis (Gr. from πρό, and γνῶσις, *knowledge*). An opinion respecting the progress and termination of a disease.

Programme (Fr.; Gr. πρόγραμμα). An old university term, signifying an outline of the speeches or orations to be delivered on a particular occasion; but now applied in a more extended sense to the outline of any entertainment or public ceremony.

Progress (Lat. progressus, *a going forward*). The state journeys of royal personages were called by this name in old English etiquette. In the reigns of Elizabeth and James they were frequent, and somewhat costly to the wealthier subjects, inasmuch as they were usually honoured with the onerous privilege of affording hospitality to royalty. The *progresses* of Queen Elizabeth form the subject of a work by Mr. Nicholl. Perhaps the most celebrated progress in English history is that of James I. from Scotland to London on his accession.

Progression (Lat. progressio). In Arithmetic and Algebra, this term is synonymous with *series*. [ARITHMETICAL PROGRESSION; GEOMETRICAL PROGRESSION; HARMONIC PROGRESSION.]

Prohibition (Lat. prohibitio, *a hindering*). In Law, a writ to forbid any court from proceeding in a cause then depending, on suggestion that the cause does not properly belong to that court. In modern times, the writ of prohibition is chiefly used where parties have been impleaded before the ecclesiastical courts. It issues properly out of the Court of Queen's Bench; but it may also be had in some cases out of the Chancery, Common Pleas, or Exchequer. It is the proper remedy where the court against which it is sued has exceeded its jurisdiction in taking cognisance of matters not properly belonging to it. It is granted on motion; but if the question of jurisdiction be doubtful, the court directs the party suing the writ to *declare in prohibition*, i. e. to bring an action against the other party, praying that a writ of prohibition may issue, and gives judgment that the writ do or do not issue, as justice may require.

Projectile (Lat. projicio, *I throw forward*). In Gunnery, a body designed to be projected by the force of gunpowder.

It was shown in the article GUNNERY that the resistance of the air materially retards a projectile in its flight, and that elongated projectiles are less retarded than spherical ones of the same weight. The retardation of a projectile is also greatly influenced by the form of its head, and to some extent by that of its hind part. Newton, in his *Principia*, gives a form of body which would, in passing through a fluid, experience less resistance than any other (fig. 1); and Piobert proposes the form represented in fig. 2, in length five times its greatest diameter, and with its largest section

Fig. 1.

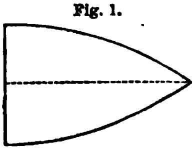


Fig. 2.

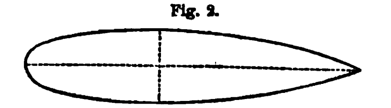


placed at two-fifths of the length of the projectile from its base. This form is very nearly

followed by Mr. Whitworth in some of his projectiles. In the last century, Dr. Hutton and Borda respectively carried on experiments upon bodies of different forms, moving with low velocities; and from Borda's experiments it appeared that the ogival form of head experienced the least resistance. A recent experiment, made under direction of the Ordnance Select Committee, to determine the relative retardations of elongated projectiles of equal weight (average 41 lb.), having similar bases, but differently formed heads, and fired at nearly equal high velocities, gave the following results:—

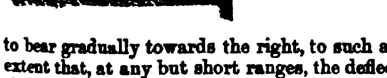
Form of projectile	*Loss of velocity in 460 yards* ft. per second
Cylindro-ogival	70
Cylindro-conoidal	98
Cylindro-parabolic	111
Cylindro-hemispherical	112
Cylindro-conical	117
Cylindrical or flat-headed . . .	170

The ogival form of head was less retarded than any other, and the conoidal head, used in our service, was next in the scale. The flat-headed projectile, as might be expected, experienced very great resistance.

The form of a projectile also affects its flight as regards deviation from the line of fire. When a round shot is fired from a smooth-bored gun, its deviation is uncertain, and depends upon the rotation which it has received, and which varies by reason of certain varying causes. Windage is the first and great cause of irregularity in flight; other causes of deviation, such as imperfect form, roughness, and want of homogeneity in a shot, will not be entered upon here, as they should be overcome by improving manufacture.

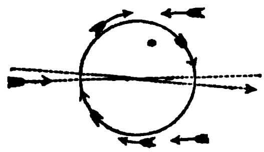
By reason of windage, when a shot is propelled, it bounds and rebounds along the bore, and finally leaves the muzzle in an accidental direction, and with a rotatory motion depending chiefly on the position of its last impact against the bore. A shot, the last impact of which is against the right side of the bore, will tend at first towards the left; but will have a rotation from left to right (fig. 3), which will cause it

Fig. 3.



to bear gradually towards the right, to such an extent that, at any but short ranges, the deflection will be to the right of the line of fire. The probable reason of this, as shown by Robins, is, that as the air in front of the ball is greatly condensed, its friction offers great resistance to the ball, behind which there is almost a vacuum, and therefore no counterbalancing force; hence the ball will tend to deflect in the opposite direction to that at first given to it. According to Magnus, if a ball leaves a gun, its fore part rotating on a vertical axis from left to right, it causes to rotate with it a portion of air; this is opposed to the resisting atmosphere on the left side, but acts with it on the right side (fig. 4). There will therefore be greater

Fig. 4.

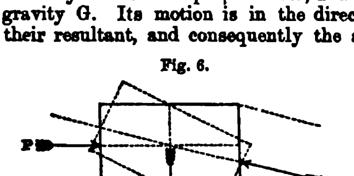


pressure on the left side than on the right, and so the ball will deflect to the right. With any other direction of rotation there will be corresponding deviation; in one case only will there be none, viz. when the ball rotates on an axis parallel to the axis of the bore, or coincident with the line of fire.

To give the projectile such a rotation is the object of rifling a gun, and the various methods of accomplishing this object are treated of in the article RIFLED GUNS. Elongated projectiles, the advantages of which have been noticed in the article GUNNERY, can be successfully fired from rifled guns, although they cannot be advantageously used with smooth-bored pieces, because they turn over during flight.

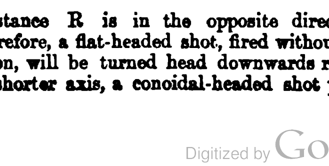
If to a flat-headed body, suspended horizontally from its centre of gravity, a pressure be applied before and below such centre of gravity, the head will thereby be depressed. If a force be similarly applied to a conoidal-headed body, its head will be raised. This is capable of easy proof either mathematically or by experiment. Now, the resistance of the air always does so press on the head of an elongated shot during flight, as shown in figs. 5 and 6. The shot is

Fig. 5.



acted on by the force of propulsion P, and that of gravity G. Its motion is in the direction of their resultant, and consequently the air's

Fig. 6.



resistance R is in the opposite direction. Therefore, a flat-headed shot, fired without rotation, will be turned head downwards round its shorter axis, a conoidal-headed shot point

upwards. But the imparting a rotatory motion to the projectile round its longer axis gives stability to that axis, and prevents the projectile from turning over.

The elongated projectile fired from a rifled gun is, however, in practice found to deviate from the line of fire to an extent more or less constant, and either to right or left according to the shape of the head, and the direction of rotation of the projectile. A conoidal-headed shot, fired with a right-handed rotation (i.e. a rotation from left to right of a spectator looking from behind the gun), will always deviate to the right; a flat-headed shot, with similar rotation, to the left. If the rotation is reversed, opposite results will ensue. An explanation of this phenomenon would extend beyond the limits of this article, but it may be briefly stated thus; take, for instance, the service cylindro-conoidal shot with right-handed rotation, as from the Armstrong gun: the resistance of the air will cause its point to be deflected to the right, and this resistance then acts obliquely on the whole projectile, and so deflects it to the right. This constant deviation is called by artillerists *derivation*, a word adopted from the French, and it must be allowed for in laying the gun. [SIGHTING ORDNANCE.]

The velocity of rotation, which an elongated projectile requires to keep its rotation stable round its longer axis, will depend upon the initial velocity, form, and density of the shot, and the position of its centre of gravity. As the initial velocity increases, the resistance of the air, tending to upset the projectile, becomes greater. Long projectiles are more easily turned over than short ones of equal weight, for the upsetting force acts with longer leverage. The same applies to a shot with its centre of gravity far back. Flat-headed projectiles are more easily turned over, for the air acts directly on their heads, instead of gliding by as with a pointed or rounded head. The less the density of a shot in proportion to size, the more rapidly will the air's resistance decrease the shot's velocity of rotation.

The projectile, therefore, must be made according to these laws, or else, to meet any of these cases, a very high velocity of rotation must be given to it, and this is objectionable, as causing (1) a very great strain on the metal of the gun, (2) extreme deflection upon grazing, and (3) too great a lateral spread of the pieces of shell.

It now remains to notice the best form and material of projectile for the various purposes of war. And, first, as regards the great problem of the modern science of artillery, the penetration of iron armour-plate. The materials used in the manufacture of projectiles for this purpose have been cast iron, wrought iron, and steel. Service cast-iron shot, cast in sand in the usual manner, are found to be very inefficient, breaking up easily on impact, though penetration has been obtained by them. The heaviest cast-iron shot yet fired in this country were those from the Horsfall gun; one weighing 279 lb. with an initial velocity of 1,631 feet, completely penetrated the 'Warrior' target at 200 yards, doing great damage; but at 800 yards, similar shot, though having a velocity on striking of 1,300 feet, failed to penetrate. A fifteen-inch cored cast-iron shot, weighing 430 lb., fired with 35 lb. of powder from the United States' monitor 'Weehawken,' shattered, at about 300 yards' range, the armour of the Confederate iron-clad 'Atlanta,' doing frightful damage; but an eleven-inch ball of 169 lb., with 20 lb. of powder, did not break the same armour. The 'Atlanta's' armour, however, was composed only of laminated plates of the aggregate thickness of 4½ inches, very inferior to a solid plate of the same thickness, and was backed by yellow pine, a wood very inferior to teak. Good results have been obtained from some chilled cast-iron shot proposed by Major Palliser; and if by further experiments we can obtain shot of this nature, possessing hardness enough for penetration, without too much toughness, they will be very valuable for use against iron-clads; for we shall obtain the advantage of their breaking into fragments after penetrating, besides saving much expense.

Wrought-iron shot have been occasionally tried. They never break up, but are much *set-up* or altered in form after impact. Experiments have all gone to prove that wrought iron, though somewhat superior to ordinary cast iron, is far inferior to steel, and is not to be recommended as a material for projectiles to be used against iron plates.

Undoubtedly by far the most damaging projectiles yet tried against armour-plated vessels are steel shells, and to Mr. Whitworth belongs the honour of first proving that a shell could be sent through an iron-plated ship of war. His shell and that of Sir W. Armstrong differ considerably; the former is solid at the head, and open at the rear to receive the bursting charge, being afterwards closed by a screwed-in steel cup; the latter is open in front, and a hollow cast-iron head is screwed on, which breaks up on impact. The latter form seems the best, as allowing the force of the bursting charge to act forwards instead of backwards. The terrible effects of the 612 lb. steel shell at 1,000 yards on the 'Warrior' target were greater than any yet seen. In fact, it is now established that the 'Warrior' target can be easily pierced at 2,000 yards by a shell containing a bursting charge of 24 lb. of powder.

During some experiments lately made in Russia, some steel shells, manufactured by Krupp, of Essen in Prussia, penetrated a target covered with 4½-inch armour-plates. These projectiles were made of the very best and most costly description of steel.

As regards form, elongated projectiles have far greater power of penetration than spherical shot. Their comparative effects may be thus summed up: the elongated projectile striking a plate with the same momentum as a spherical

one, will penetrate deeper than the latter, for, although the force of the blow given by each projectile will be the same, there will be a greater amount of resistance due to the greater diameter of the spherical projectile; consequently its penetration is less than that of the elongated projectile, but the force of the blow is more spread, and the shattering effect is greater. Experiments also led the Committee on Iron to report that conical-ended shot are superior in accuracy and range to flat-ended projectiles, and that, except perhaps for oblique firing, they are also superior for penetration. The following is the evidence of Sir W. Armstrong: 'I do not see how you can produce with steel round shot an effect comparable to the effect which can be obtained with cylindrical rifled shot. With respect to employing steel spherical shell, capable of penetrating iron plates, I consider it out of the question. It is only by means of the elongated form of the projectile that we can produce a steel shell capable of piercing an iron plate, and it is due to the principle of rifling that the elongated form can be adopted.'

The experiments conducted against the 'Hercules' target, which has a total thickness of 4 ft. 10½ in., the outside plates being respectively 9 in. and 8 in. thick, have shown that a ship may be constructed proof against even a steel shot of 580 lbs. weight, striking with a velocity of 1,310 feet per second. The Americans have turret ships carrying 14 in. of armour; and such vessels we must in any future contest expect to encounter.

The following table, extracted from Major Owen's *Lectures on Artillery*, gives the effects produced on the same description of target (the 'Warrior') by various projectiles, fired with different charges, and at several ranges.

For breaching masonry, whether protected by iron plates or unprotected, heavy solid shot must be used, followed by shells with large bursting charges. Ricochet fire is now so entirely abandoned for shell fire, that the elongated shell holding a large bursting charge seems the best projectile for other siege purposes.

In the field, Sir W. Armstrong's segment shell has with us superseded all other projectiles, being capable of use either as shot, shrapnel shell, common shell or case, though as shot it is no better than the common solid shot and much more costly, while it is not thoroughly efficient as either common shell or case, and a special case shot, invented by Lieut. Reeves, R.A., is about to be introduced on this account; and it has lately been decided that another form of shrapnel shell (Boxer's) is far superior in destructive effect.

Finally, wherever it is practicable, the gun should be made for the projectile, and not the projectile for the gun, and both should be of as simple construction as possible. It is necessary in the first place to determine the conditions of velocity, form of shot, &c., requisite to obtain accuracy, range, and penetration; also the shape of the projectile best adapted to the destructive purpose for which it is intended; secondly, to contrive a gun which shall give a certain projectile the necessary initial velocity and velocity of rotation, and which shall combine excellence and simplicity of construction with the requisite weight, strength, and durability.

For further information, see GUN; GUNNERY; RIFLED GUNS; &c.; and the following works: Major Owen's *Lectures on Artillery*, 4th edit.; Owen's *Motion of Projectiles*; Holley *On Ordnance and Armour*; *Reports of the Committee on Iron Plates*, Bluebooks; Captain Harrison in *Royal Artillery Institution Proceedings*, vol. iv.; *Report of Armstrong and Whitworth Committee*; &c.

PROJECTILE. In Mechanics, a body which having had a motion in space impressed on it by the action of an external force, is abandoned by this force, and left to pursue its course. Thus, a stone thrown from the hand or a sling, an arrow shot from a bow, and a bullet discharged from a cannon, are projectiles while they continue in motion.

Projection (Lat. projectio, *a throwing forward*). In Astronomy, this term is employed when a star actually occulted by the moon appears to be projected on its disc. It is an optical illusion which frequently occurs.

Projection, Method of. A modern and very powerful method of investigating and generalising the properties of plane as well as of non-plane curves. In general any two curves traced on the same cone may be considered as projections one of the other. The vertex of the cone is called the point or *centre of projection*, and one, at least, of the curves is usually conceived to lie in a plane, the *plane of projection*. Each generator of the *projecting cone* is called a *projecting ray*.

The *graphic*, as distinguished from the *metrical* properties of *non-plane curves*, may be advantageously studied by means of their plane projections. To illustrate this, we may observe that: 1. The plane projection of a non-plane curve must be of the same order as the latter; for the number of intersections, with the projection of any right line, must necessarily be equal to the number of points in which the projecting plane of that right line meets the non-plane curve. 2. The *class* of the projection will be equal to the *rank* of the curve; in other words, to the *order* of its developable osculatrix [CURVE]; for the latter is equal to the number of tangents to the curve which meet any projecting ray, and therefore to the number of tangents to the projection which pass through the point where that ray intersects the plane of projection. 3. The number of *stationary tangents* (points of inflection) of the projection will be equal to the *class* of the curve; for the latter is equal to the number of osculating planes which pass through the centre of projection, and each such osculating and projecting plane contains two consecutive tangents of the curve, and therefore two *coincident consecutive tangents* of the projection. 4. To every *stationary point* on the curve corresponds a stationary point on the projection; for through such a stationary point pass three consecutive tangents, a property which is clearly projective. 5. The number of *double points* on the projection will indicate how many projecting rays meet the curve in two points, coincident or distinct; it will be equal, therefore, to the sum of the *real* and *apparent* double points of the curve, or, in other words, to the number of '*lines through two points*' which pass through a given point. [CURVE.] 6. Double tangents of the projection also arise from apparent as well as real double tangents of the curve, and their number merely indicates how many '*planes through two lines*' pass through an arbitrary point (the vertex). From the above analysis it will be easily understood how Plücker's equations, connecting the ordinary singularities of plane curves, may be generalised to suit the case of non-plane curves. Mr. Cayley has, in fact, done this in a paper published in the *Cam. and Dublin Math. Jour.* vol. v.

We proceed to notice some of the more important properties of *plane projections of plane curves*. It is obvious, from what has been already stated, that the ordinary singularities of such curves all reappear in their plane projections; these singularities are included in the so-called *projective properties* of figures. It should be here stated, however, that such properties are not exclusively *graphic*. Many *metrical* properties are also projective, and, what is most important, anharmonic ratios of points and lines are so. [ANHARMONIC RATIO.] Thus a pole and its polar with respect to any conic become by projection a pole and polar of another conic; for the polar A of any point a with respect to a conic Σ, is simply the locus of the harmonic conjugate of a with respect to the intersections with Σ of any transversal through a. This simple theorem is extremely rich in consequences; we cannot, however, dwell upon them, and must refer the reader to Poncelet's classic work on the *Propriétés Projectives des Figures*, or to the writings of Chasles, Steiner, Salmon, &c. We will merely add that many important theorems with respect to conics may be easily demonstrated by remembering that, with a proper choice of the centre and plane of projection, any conic may be projected into a circle, and at the same time any line in the plane of that conic into the line at infinity. If this be done with the above conic Σ and polar A, for instance, the projection of the pole a will manifestly be the centre of the circle into which Σ is projected. Further, two non-intersecting conics may always be projected into two circles, and if the former have double contact, the chord of contact being imaginary, the latter will be concentric.

We have still to mention the plane projections of figures obtained by assuming the centre of projection to be infinitely distant. In this case the projecting cone becomes a *projecting cylinder*. The projection is termed *orthographic* or *orthogonal* when the plane of projection is perpendicular to the generators of the projecting cylinder; in other cases it is called oblique. In descriptive geometry, for example, orthographic projections of objects upon a vertical and a horizontal plane are taken; whilst in Cartesian coordinates a figure

in space is determined by its orthographic projections on three rectangular coordinate planes. In orthographic projection, lines parallel to the plane of projection are not altered in length, others are shortened in the ratio of unity to the cosine of their inclination to the plane of projection. The area of the orthogonal projection of a figure is equal to that of the figure itself multiplied by the cosine of the inclination of its plane to that of projection. The orthogonal projection of a circle, inclined to the plane of projection, is always an ellipse whose centre is the projection of the circle's centre, whose major axis is equal to the diameter of the circle and parallel to the intersection of its plane with the plane of projection, and whose minor axis is of course equal to that diameter multiplied by the cosine of the inclination of the two planes.

A useful form of orthographic projection, suitable for the representation as well as for the investigation of geometrical figures whose principal lines, like those of a parallelopiped, are parallel to one of three mutually rectangular axes, was invented by Farish, and termed *isometrical*; since, the plane of projection being equally inclined to the three axes, all distances parallel to the latter are shortened in the same ratio, viz. that of $\sqrt{3} : \sqrt{2}$. The projections of the principal lines of the figure make an angle of 120° with each other. The projections of level lines, i.e. of lines parallel to the plane of projection, are of the same length as their originals, and are necessarily perpendicular to the projections of one set of principal lines and inclined at an angle of 30° to those of the other two sets. The lines of greatest slope on the principal planes are represented by lines parallel to the projections of one set of principal lines, and consequently inclined to those of the other two at an angle of 60°. Such lines are shortened by projection in the ratio of $\sqrt{3} : 1$. Every circle on a principal plane is projected into an ellipse with its major axis parallel to the projections of the lines of level and equal to the diameter of the circle, the ratio of its two axes being that of $\sqrt{3} : 1$.

Projection of the Sphere. On account of their importance in the construction of maps, charts, &c. we have reserved for a short separate notice the more important methods of projecting figures traced on the surface of a sphere.

1. *Orthographic Projection.*—The general character of this method having been already explained, it is only necessary to add that orthographic projections of the sphere are usually made either on the plane of the equator or on the plane of a meridian. When on the plane of the equator, the meridians are all represented by straight lines intersecting in the centre of the projection, and the parallels of latitude by circles whose radii are respectively equal to the cosines of the latitude. When the representation is on the plane of a meridian the other meridians are represented by ellipses, and the parallels of latitude by straight lines parallel to the diameter of the projection. The chief defect of orthographic projections of a hemisphere is, that near the circumference of the representation the figures are greatly crowded and distorted.

2. *Stereographic Projection.*—The plane of projection may here be that of any great circle; the centre of projection is then taken at one of its poles. Accordingly the spherical figure and its projection are *inverse* to one another [INVERSION]; hence all circles are projected either into straight lines or into other circles, and the angle between any two intersecting curves on the sphere is preserved unchanged in the projection. The first of these important properties was known to Hipparchus and Ptolemy, the former of whom invented the projection and gave it the name of *planisphere*. The second property was first demonstrated by Dr. Halley in the *Phil. Trans.* for 1696; an important consequence being that corresponding small portions of the spherical figure and its projection are *similar*.

3. *Gnomonic or Central Projection.*—In this projection, also described by Ptolemy, the eye is situated at the centre of the sphere, and the plane of projection is a plane which touches the sphere at any point assumed at pleasure. The point of contact is called the *principal point*; and the projections of all other points on the sphere are at the extremities of the tangents of the arcs intercepted between them and the principal point. As the tangents increase very rapidly when the arcs exceed 45°, and at 90° become infinite, the central projection cannot be adopted for a whole hemisphere.

A modification of this projection consists in taking the plane of one of the polar circles as the plane of projection. It is then called a *polar projection* of the sphere.

4. *Globular Projection.*—This projection was proposed by Lahire. The plane of any great circle being taken as the plane of projection, a point in its axis, *outside the sphere*, is assumed as the centre of projection. In order that the representation of the more distant hemisphere may be as little distorted as possible, the shortest distance from the eye to the sphere must have to the radius the ratio of the side to the diagonal of a square.

5. *Conical Projection.*—The centre of projection being still the centre of the sphere, the *surface* of projection is now a right cone which may either touch the sphere in a parallel of latitude or intersect it in two such parallels. The conical surface is ultimately supposed to be unfolded into a plane, when, manifestly, meridians will be represented by right lines converging to a point, and parallels of latitude by circular arcs around that point as centre.

6. *Cylindrical Projection.*—The centre of projection being the same as before, the surface of projection is here supposed to be a *cylinder* touching the sphere at the equator. When the cylinder is unfolded, meridians and parallels of latitude are each represented by parallel lines, the lines of longitude, corresponding to

successive degrees, being equidistant, and perpendicular to the lines of latitude whose distance apart increases rapidly with the latitude. MERCATOR'S PROJECTION may be considered as a modification of the present one, the *projecting rays* being curved instead of straight.

7. *Homolographic Projection.*—This, like Mercator's, is not a proper projection. It may be described as a representation of the sphere on the principle of the conservation of relative areas, in other words, so that the areas of any two portions of the map shall have the same ratio to each other, as the areas of the corresponding portions on the sphere. Flamsteed solved the problem approximately; Cauchy investigated it mathematically; and Babinet has, we hear, published maps constructed on the basis of Cauchy's calculations.

Projecture (Lat. projectura). In Architecture, the jutting or leaning outwards of the mouldings and other members of architecture beyond the face of a wall, column, pilaster, cornice, &c.

Prolapsus (Lat. part. of prolabor, *I fall forward*). A protrusion or falling down of a part of a viscus that is uncovered.

Prolate Spheroid. In Geometry, a spheroid produced by the revolution of an ellipse about its major axis; so called in opposition to the *oblate* spheroid, which is produced by the revolution of the ellipse about its minor axis. [SPHEROID.]

Prolegomena (Gr.). In Literature, preliminary or introductory observations or dissertations prefixed to any work.

Prolegs. In Entomology, the fleshy exarticulate, pediform, often retractile organs, which assist various larvæ in walking and other motions, but which disappear in the perfect insect.

Prolepsis (Gr. *an anticipation*). In Rhetoric, a figure by which the speaker anticipates and answers imaginary objections to the sentiments which he is urging.

Proletarian (Lat. proletarius). In the constitution attributed to Servius Tullius, Roman citizens who did not possess the amount of property requisite for admission into the lowest class were so called (as it is said from proles, *offspring*, because they had only their children to offer to the state). Hence, in modern political language, the name is frequently applied to the destitute portion of the population. [CAPITE CENSI.]

Prologue (Gr. πρόλογος). A piece in verse recited before the representation of a play, and serving as an introduction to it. [EPILOGUE.]

Prolonge (Fr.). In Artillery, a rope used to drag a gun-carriage without the limber, when it is required to retire firing through a street of a village, or any narrow defile.

Prolusion (Lat. prolusio). A classical word which has been adopted in a rather general sense by authors unwilling to claim for their own productions a more ambitious designation. Thus used, the term denotes an essay or preparatory exercise, in which the writer tries his strength, or throws out some preliminary remarks on a subject which he intends to treat more profoundly. The early and fugitive pieces of some poets (as the *Culex* and others attributed to Virgil) have been termed, by critics, their *prolusions*.

Prometheans. A term applied to paper matches enclosing small glass tubes containing concentrated sulphuric acid, and surrounded with an inflammable mixture, which becomes ignited on sufficient pressure being applied to break the glass tube.

Prometheus (Gr.). In the Hesiodic *Theogony*, a son of the Titan Iapetus; but according to Æschylus, a son of Themis (*law*). It is impossible to harmonise the legends of his life and acts. In the tale of Æschylus, Prometheus, the *fore-thinker* (as his brother Epimetheus is one who takes counsel after the event), feels compassion for the misery of men, who know neither how to cook food or to build houses. Having stolen fire from heaven, he imparts the gift to mortals, who are now taught by him the arts necessary to civilise and to sweeten life. This myth, it is obvious, conveys an idea altogether opposed to that of the Hesiodic Ages, in which men are represented as beginning with a golden existence and gradually degenerating. The favour shown to men by Prometheus rouses the anger of ZEUS, who forgets the aid received from him in the war against Cronos. Zeus bids Hermes to chain Prometheus on the rocks of Caucasus, where an eagle perpetually gnaws his liver. While Prometheus is there exposed, Io in her wandering comes to him, and learns that from her is to spring his future deliverer Heracles. But the wrath of Zeus was not yet satiated. Prometheus had warned his brother Epimetheus to receive no gift from the gods; but Zeus ordered HEPHÆSTUS to mould a virgin who should receive some grace from each of the gods. Thus invested with all the charms that could attract men, PANDORA was presented by Athena to Epimetheus, who received her into his house, in which lay the cask containing under its closed lid all the evils that may afflict mankind. Pandora raised the cover, and all the evils flew out. Frightened at the result, Pandora replaced the lid and made Hope a prisoner in the cask, and thus deprived men of all alleviation of their sufferings.

It has, indeed, been contended that the shutting-up of Hope within the cask was an act of mercy, and that, as the escape of Hope would have left men to utter despair, Pandora was bidden by Zeus to replace the lid; but the genuineness of the line which contains this command is very doubtful; while the whole legend represents Zeus as inexorably hostile to men, and as unlikely to interfere in their behalf. In Mr. Grote's opinion, the point is one which does not admit of question. 'Pandora,' he says, 'does not, in Hesiod, *bring with her* the cask. . . The case is analogous to that of the closed bag of unfavourable winds which Æolus gives into the hands of Odysseus, and which the guilty companions of the latter force

open, to the entire ruin of his hopes. . . . The diseases and evils are inoperative so long as they remain shut up in the cask; the same mischief-making influence which lets them out to their calamitous work, takes care that Hope shall still continue a powerless prisoner in the inside.' (*History of Greece*, part i. ch. iii.)

In some versions of the myth Athena is the accomplice of Prometheus in the theft of fire, and his tortures on Caucasus are a punishment for his unlawful love which is returned by the virgin child of Zeus. [MINERVA.] In other legends Prometheus is called the father of DEUCALION, whom he warns to build the ark which saves from the flood the scanty remnant of mankind. After the flood, Prometheus made men from mud, and the winds breathed life into them.

Another cause for the feud between Zeus and Prometheus is given in an institutional legend which accounts for the portion of each sacrifice assigned to the gods. Prometheus, warning men that their substance would be wasted if they consumed the victims with fire, slew an ox, and, dividing the body, placed the entrails and flesh under the skin, and the bones under the fat. Zeus, being bidden to lay his hand on the portion which he desired for himself, took the fat, and his rage was kindled when he found that henceforth the bones were to be his share, while the flesh belonged to men. This version represents Zeus as taking away in consequence the gift of fire, with which men had already been made familiar.

In the Hindu traditions, the Pramantha is the wooden churn used for kindling fire with dried pieces of wood.

Promissory Note. A note or writing by which one or more persons promise to pay a certain specified sum of money at a certain date. Such documents, if drawn on proper stamps, are legal negotiable instruments enjoying the same privileges as bills. No negotiable or transferable bill or note (not being a draft on a banker) can be lawfully drawn or made for any sum under 20*s*.

Promontory (Lat. promontorium, from mons, *a mountain*). In Geography, a point of land, whether high or low, projecting into the sea. [CAPE.]

Promptuary (Lat. promptuarium, *a storehouse*). In Literature, a title sometimes given to works of the class of summaries, handbooks, and the like, in which subjects are so arranged as to be *prompt*, or ready for use.

Promulgation (Lat. promulgatio). In Jurisprudence (though not strictly in English Law), the name commonly given to the acts of publication of laws and other instruments from the date of which (unless otherwise specially provided therein) they become valid. Thus, in France, a law becomes executable as soon as it is inserted in the printed *Bulletin des Lois*.

Promuscis (Lat.). The name of the suctorious organ of the Hemipterous insects, formed by the union of the two jaws (*maxillæ*) to the lower lip, which they embrace; thus forming a jointed organ, containing four long capillary lancets and a short tongue.

Pronaos (Gr.). In Ancient Architecture, the front porch of a temple. This corresponded with the NARTHEX of the early Christians. [NAOS.]

Pronator Muscles (Lat. prono, *I make prone*). Those which are used in turning the palm of the hand downwards.

Pronoun (Lat. pronomen). In Grammar, a part of speech used in the stead of nouns, to avoid needless or inconvenient specification. Pronouns are divided into *substantive* or *personal*, and *adjective*; the latter including *possessive, demonstrative, relative, indefinite*, and *interrogative* pronouns.

Proof (Fr. épreuve, from Lat. probo, *I try* or *test*). In Engraving, an impression taken from an engraving to prove the state of it during the progress of executing it; also one taken before the letters are engraved on the plate.

PROOF. In Printing, an impression of a sheet of a work on which the errors and mistakes are marked for the purpose of being corrected. Proofs are: *first proof*, which is the impression taken with all the errors of workmanship. After this it is read by the copy, and the errors having been corrected, another impression is printed with more care, to send to the author; this is termed a *clean proof*. On it he makes his corrections and alterations: when those are altered in the types, another proof is printed (on the paper proposed for printing the work, so as to settle the margin), and read over carefully, previously to the whole number being printed off; this is called the *press proof*.

PROOF. [EVIDENCE; HISTORICAL CREDIBILITY.]

Proof of Ordnance. All guns are proved at Woolwich before being issued for service. The tests are instrumental, water (for muzzle-loading guns only), and fire proof. Any gun failing to reach the standard of any of the tests is returned for alteration or rejected.

Proof Spirit. A mixture of equal weights of absolute alcohol and water; the specific gravity of such a mixture is 0·917; but that of the proof spirit of commerce is 0·920 at 60°. The term *proof* appears to be derived from the gunpowder test. Spirit was poured over gunpowder and the vapour inflamed: if it fired the gunpowder, it was over-proof; if it burnt without igniting the powder, owing to the residuary water rendering the powder damp, it was said to be under-proof. The weakest spirit capable of firing gunpowder was the proof spirit of pharmacy, specific gravity 0·920. [ALCOHOL; HYDROMETER.]

Propædeutics (Gr. προπαιδεύω, *I instruct beforehand*). A term used by German writers to signify the preliminary learning connected with any art or science.

Propaganda (Lat.). The name given to an association, or, as it is termed, the congregation *De propagandâ Fide*, established at Rome by Gregory XV. in 1622, for diffusing a know-

ledge of Catholic or Papal Christianity throughout the world. It is a committee of cardinals and special agents of the pope, under whose presidency it meets every week. Its duties are, the superintendence and assistance of missionaries in all parts of the globe, the maintenance of recent converts, the publication of religious works in foreign languages, &c. Derived from this celebrated society, the name *propaganda* is applied in modern political language as a term of reproach to secret associations for the spread of opinions and principles which are viewed by most governments with horror and aversion.

Propagation of the Gospel in Foreign Parts, Society for the. [SOCIETIES.]

Propagation of Plants. The greater number of plants are propagated naturally by means of seeds. Many plants, however, increase by extending over the surface, on which they take root by the production of runners or lateral shoots, which spread along the surface, and root at the joints or buds, from which they send up new plants; by the developement of suckers or side shoots from the roots; and by various other natural means.

Artificially, plants are propagated by seed, by runners, suckers, offsets, dividing the tubers, layers, cuttings, grafting, budding, inarching, &c. Seeds are gathered when mature, and sown on recently stirred soil, and covered to different depths, according to the size of the seed, the nature of the soil and situation, and other circumstances. The plants formed by runners are separated from the parent plant by cutting through the runner, and removing the young plant, in order to place it elsewhere. Suckers, slips, or side shoots from the roots, are separated from the parent plant by being slipped down, or cut off, so as to carry with them a portion of fibrous roots; and they are afterwards planted in suitable soil, &c. *Offsets* are small bulbs which are produced round the base of larger ones, and, being taken off and planted, become plants. *Tubers* are underground stems, containing leaf-buds; and these may be separated and planted entire, or cut into as many pieces as there are buds, in either of which cases new plants will be formed. *Layers* are branches or shoots of either woody or herbaceous plants, which are bent down, and a portion of their length buried a few inches in the soil; that portion having been previously wounded by cutting, bruising, or twisting, which, by checking the descent of the sap, gives rise, after a certain period, to the production of roots. After these roots are formed, the portion of the layer which has produced them is separated from the main stock or parent plant, and planted by itself. *Cuttings* are portions of shoots, either of ligneous or herbaceous plants, entirely separated from the parent and planted under suitable conditions, which vary with different species. They are made of the young shoots with the leaves on, or of the ripened wood either with or without its leaves; and after they have, either in a herbaceous state with the leaves on, or with the wood mature and with or without the leaves, been properly prepared and planted, they form roots at their lower extremity, each cutting becoming a perfect plant. In general, cuttings should be taken from those shoots of a plant which are nearest the soil; because, from the moisture and shade there, such shoots are more predisposed to emit roots than those on the upper part of the plant; neither excessively vigorous nor very weakly shoots should be chosen, and the young or last-formed shoots are in most cases to be taken in preference to older shoots, though in some instances it is necessary that they should be nearly matured before being removed. The cutting is to be prepared by paring away with a very sharp knife its lower extremity just below a joint, the lenticels or root-buds being there most abundant. When the cutting is planted, the principal part of the art consists in making it quite firm at the lower extremity, so as completely to exclude the air from the wounded section. Cuttings emit roots at this section, either in consequence of the action of the accumulated sap in the cutting, as in the case of the ripened wood in deciduous trees and shrubs; or in consequence of the joint action of the accumulated sap and of the leaves, as in the case of cuttings of soft wood with the leaves on, and in a living state. A few plants are propagated by cuttings of the leaves, the petiole of the leaf being slipped off from the parent plant, and probably containing the latent embryos of buds; and some plants are increased by fragments of the fleshy leaves themselves, as in *Begonia* and *Gloxinia*.

Grafting and budding are processes which have been already explained. [BUDDING; GRAFTING.] Inarching may be described as a species of grafting, in which the scion is not separated from the parent plant till it has become united with the stock.

Propeds. The name given by Kirby to the soft, fleshy, inarticulate, pediform appendages of certain larvæ, placed behind the true feet, and disappearing in the mature insects.

Propeller. [STEAM NAVIGATION.]

Propempticon (Gr. from προπέμπτω, *I send forth*). In Literature, a poetical address to one about to depart on a journey. Perhaps the finest in existence is that of Schiller to the duke of Weimar when about to visit France.

Proper. In Heraldry, any object represented of its natural colour is so termed.

Proper Motion. In Astronomy, the real motion of the sun and stars through space, as opposed to apparent motion, produced by the actual movement of the earth. It was first suspected by Halley in 1718. (*Phil. Trans.* vol. xxx. pp. 736–8.)

Property. In Logic, a predicable which denotes something essentially conjoined to the essence of the species. There are enumerated in books on logic four kinds of property, which are termed *universal, but not peculiar; peculiar, but not universal; universal and pecu-*

liar; universal and peculiar, but not at every time. The last kind is more properly designated as *accident*. [LOGIC; PREDICABLE.]

Prophet. The Greek word προφήτης denoted strictly one who speaks for another, and especially one who speaks for a god and interprets his will to men. Thus Teiresias is called by Pindar the prophet or interpreter of Zeus, and the Pythian priestess is called the prophetess of Apollo, and poets the prophets or interpreters of the Muses. In the New Testament the word is used commonly by St. Paul and in the Acts of the Apostles to signify an interpreter of Scripture, a preacher. (Liddell and Scott, *Greek and English Lexicon*, s.v. προφήτης). In the Hebrew Scriptures, persons who declared the will of God are called at first *seers*, and afterwards *nabi*, or *prophets*, who spoke as moved by the Spirit of God; but prophecy 'in its more extensive meaning comprehended the whole course of religious education,' this instruction being given in schools called the schools of the prophets. The outward gestures of the prophets indicated sometimes an excitement not unlike that of the Pythian priestess, as in the instances recorded of King Saul. (1 Sam. x. 11; xix. 24.) The word *prophecy* was also used to express the occurrence of marvellous events. Thus the body of Elisha is said to have prophesied, in reference to the revivification of the dead Moabite on coming into contact with his bones. A further meaning of the word was that of prediction or the foretelling of future events; and the Book of Jonah, which relates the disappointment and indignation of the prophet at the non-fulfilment of his prophecy in its literal meaning, seems pointed at an exaggerated theory then prevalent respecting this characteristic. The great Hebrew prophets were, pre-eminently, fearless spiritual teachers, who appeared among their countrymen to declare the Divine Will at all costs and at every sacrifice, and to assert the existence of a moral law which godless rulers and a superstitious people were tempted to ignore or to defy. 'But, setting aside their Divine commission, the prophets were the great constitutional patriots of the Jewish state; the champions of virtue, liberty, justice, and the strict observance of the civil and religious law, against the iniquities of the kings and of the people.' (Milman, *History of the Jews*, book viii.) The Old Testament contains sixteen prophetical books, viz. those of the four termed the great prophets, Isaiah, Jeremiah, Ezekiel, Daniel, and the twelve lesser prophets, Hosea, Joel, Amos, Obadiah, Jonah, Micah, Nahum, Habakkuk, Zephaniah, Haggai, Zechariah, Malachi.

Prophylactic (Gr. προφυλακτικός, from προφυλάσσω, *I defend*). In Medicine, this term is used to denote the means employed to prevent disease.

Propionic Acid. *Metacetic acid. Metacetonic acid.* A crystalline acid closely related to acetic acid and formed by oxidising oleic acid. It is also produced by the reaction of cyanide of ethyl and alcoholic solution of potash, and by the action of sodium ethyl upon carbonic acid.

Propolis (Gr.). A name applied to the substance employed by bees in closing up crevices in their hives, and in strengthening the margins of the cells of the comb. It is a glutinous resin, of a reddish-brown colour and an aromatic odour, and in time acquires a firm consistence. It is collected from the wild poplar and other trees. [HIVES.]

Proportion (Lat. proportio). In Arithmetic and Geometry, the equality or similitude of ratios; four numbers or magnitudes being said to be proportional, or in proportion, when the ratio of the first to the second is the same as the ratio of the third to the fourth, or when the first divided by the second gives the same quotient as the third divided by the fourth.

The definition of proportion has given rise to much controversy among writers on the elements of Geometry. Euclid's celebrated definition in the fifth book, whatever may be said in favour of its ingenuity and exactness, is found by experience to be much too complicated and refined to be understood by beginners; and accordingly many attempts have been made to substitute for it one more intelligible; but, on account of the difficulty of defining the term *ratio* in such a manner as to include incommensurable quantities, none of these attempts can be said to have been perfectly successful. This imperfection, however, must be understood as belonging merely to the metaphysical accuracy of the definition, for many of the treatises which have been composed with the view of superseding Euclid's have all the simplicity and elegance which can be desired. On this subject the reader may consult Barrow's *Mathematical Lectures*, the notes to Playfair's *Euclid*, Camerer's *Euclid*, Berlin 1825; De Morgan *On the Connexion of Number and Magnitude*, 1836; and the article 'Proportion' in the *Penny Cyclopædia*.

Proportion consists of, at least, four terms; of these the two which constitute the antecedents, as well as the two which form the consequents of the equal ratios, are said to be *homologous terms*. When, in a proportion, the antecedent of one ratio is equal to the consequent of the other, the three unequal magnitudes are said to be *continual* proportionals; in other cases the proportion is said to be *discrete*. Two quantities of the same kind are said to be *directly* proportional to two other quantities like each other and respectively related to the first, when in equal ratios the two related quantities are either both antecedents or both consequents. When the quantity related to the antecedent of one ratio, however, is the consequent of the other, the proportion is said to be *inverse*, and two of the magnitudes are said to be *inversely* or *reciprocally* proportional to their, respectively, related magnitudes.

It is a property of proportional numbers, derived immediately from the definition, that the product of the first and fourth terms is equal to the product of the second and third.

Hence, when three terms of a proportion are given, the fourth can be found. This is the object of all questions in the Rule of Three.

The preceding remarks apply exclusively to *geometrical* proportion; i.e. when the proportion consists in the equality of ratios. Writers on arithmetic also mention *arithmetical* proportion, and *harmonical* proportion, for which see the respective terms. [ARITHMETICAL PROGRESSION; HARMONIC PROGRESSION.]

PROPORTION. In the Fine Arts, the most proper relation of the measure of parts to each other and to the whole. The Greeks used the word συμμετρία (*symmetry*), to express this idea. In many instances *proportion* may be considered almost synonymous with *fitness*, though there is a distinction between them; since every form susceptible of proportion may be considered either with respect to its whole as connected with the end designed, or with respect to the relation of the several parts to the end. In the first case, fitness is the thing considered; in the second, proportion. Fitness, therefore, expresses the general relation of means to an end, and proportion the proper relation of parts to an end. It is hence needless to dwell on the intimate connection that exists between beauty and proportion, in all complex forms.

Proportions, Definite. In Chemistry. [AFFINITY.]

Proportional Compasses. Compasses with two pairs of opposite legs, by which distances are enlarged or diminished in any proportion.

Proportional Logarithms or **Logistic Logarithms.** This name was given to tables (intended to be used with the old *Nautical Almanac*) by which the fourth proportional to three given numbers, of which the first never varied, could be conveniently found. They are now rarely used.

Proportional Parts. A name given in logarithmic and other tables, to other small tables introduced for the purpose of facilitating interpolation. In each set of tables, the use of the table of proportional parts is usually fully explained.

Proportional Scales. [SCALES.]

Proportionals. The terms of a proportion; of these the first and last are the *extremes*, and the intermediate the *means*, or the *mean* when the proportion consists of only three terms. [PROPORTION.]

Proposition. In the scholastic system of Logic, a proposition is defined *a sentence indicative*; i.e. a sentence which affirms or denies. Thus, sentences in the form of command or question are excluded from the character of propositions. Logical propositions are said to be divided, first, according to substance, into *categorical* and *hypothetical*; secondly, according to quality, into *affirmative* and *negative*; thirdly, according to quantity, into *universal* and *particular*. 1. A categorical proposition affirms or denies absolutely, as 'Man is mortal.' A hypothetical proposition is defined to be two or more categoricals united by a conjunction, as 'If Caius is man, he is mortal.' There are several sorts of hypothetical propositions: *conditional*, *disjunctive*, *causal*, &c. But all disjunctive hypotheticals may be resolved into two or more conditional propositions, 'Either A is B or C is D,' being equivalent to 'If A is not B, C is D,' and 'If C is not D, A is B.' Hence their disjunctive character arises only from their form, their meaning being in all cases conditional. In such propositions no assertion is made of the truth of either proposition, all that is maintained being the inferribility of the one from the other. Thus in the proposition, 'If the Koran comes from God, Mahomet is the prophet of God,' the real subject of predication is the whole proposition, 'Mahomet is the prophet of God,' the affirmation being that this is a legitimate inference from the proposition, 'The Koran comes from God.' Hence the subject and predicate of hypothetical propositions are names of propositions. (Mill, *System of Logic.*) 2. An affirmative proposition is one whose copula (or conjunction) is affirmative, as 'Man is mortal;' a negative proposition has a negative copula, as 'Tyrants are not happy.' 3. A universal proposition is when the predicate is said of the whole of the subject, as 'All men are mortal,' 'Caius is mortal;' a particular, when it is said of part of the subject only, as 'Some men are rich.' To these two species may be added the indefinite proposition, when the subject has no sign of universality or particularity, or is a singular noun, which is either universal or particular according to the matter. The matter of a proposition is said to be either *necessary*, *impossible*, or *contingent*; and if the matter of an indefinite proposition be either of the two former, it is equivalent to a universal; if the last, to a particular: e.g. 'birds fly,' i.e. all birds —universal. 'No birds are quadrupeds;' here the matter is impossible, and the proposition universal. 'Birds sing,' i.e. some birds—particular. The fourfold division of propositions according to quality and quantity is denoted by arbitrary signs; e.g. A stands for a universal affirmative, in the logic used at Oxford; E for a universal negative; I for a particular affirmative; O for a particular negative. A categorical proposition is composed of two terms united by a copula. [TERM; COPULA.] The first term, i.e. that of which the other is affirmed or denied, is the *subject*; the other (that which is affirmed or denied respecting the first) the *predicate*. In the collocation of our language, the subject usually, but not invariably, precedes the predicate. Thus, 'Diana of the Ephesians (subject) is great' (predicate), is transposed into 'Great is Diana of the Ephesians.' In some languages, as Greek and Latin, the latter form of collocation is not less natural or usual than the former. When the subject of a proposition is a common term [TERM], it is said to be *distributed*, when the universal sign (*all*, *no*, *every*, &c.) is prefixed and the proposition is consequently universal. The predicate is said to be *distributed* in all ne-

gative but not in affirmative propositions, inasmuch as a negative proposition denies that any part of the predicate agrees with the subject, whereas an affirmative can *never* assert that every part of the predicate agrees with the subject; i.e. can never do so necessarily, by the logical force of the proposition, although it may undoubtedly happen that the predicate agrees with the subject and with nothing else: e.g. 'Cæsar was the first Roman emperor.' Two propositions are said to be opposed, when, having the same subject or predicate, they differ in quantity, in quality, or in both. The two universals (A and E) are termed *contraries* to each other; the two particulars (I and O) *subcontraries*; the universals and particulars (A and E, I and O) *subalterns*; A and O, or E and I (those which differ both in quantity and quality), *contradictories*. A proposition is said to be converted when its terms are transposed; i.e. when the subject is made the predicate, and the predicate the subject. [CONVERSION.]

It must be carefully remembered that propositions relate not to words or to our ideas of things, but to things or facts, in other words to phenomena; all propositions, affirmative or negative, being assertions that of two phenomena one agrees with, or includes, or is connected with the other, or that it does not so agree with it. The proposition 'Fire burns' cannot be resolved into the assertion that our idea of fire causes our idea of heat: it can mean only that the natural phenomenon fire causes or is followed by the natural phenomenon heat. If we wish to assert anything respecting ideas, we speak of those ideas by name, as when we say, 'The ideas entertained of the Deity have a great effect on the characters of mankind.' 'The notion,' says Mr. Mill, 'that what is of primary importance to the logician in a proposition is the relation between the two ideas corresponding to the subject and predicate (instead of the relation between the two phenomena which they respectively express) seems one of the most fatal errors ever introduced into the philosophy of logic.'

PROPOSITION. In Mathematics, a theorem proposed to be demonstrated, or a problem in which something is proposed to be done.

Proprætor. A Roman magistrate, bearing to the prætor the relation which the proconsul bore to the consul. [PROCONSUL.] Under the emperors, proprætors, as distinguished from proconsuls, were appointed as governors to the imperial provinces, the latter being the servants of the senate.

Propylæa (Gr. προπύλαια). Strictly, the entrance to a temple or sacred enclosure. But when the term is not specially used of Egyptian temples, it denotes generally the entrance to the Acropolis of Athens. These propylæa were completed in the time of Pericles, B.C. 432, the cost being upwards of 2,000 talents. The building was in the Doric style, and the architect was Mnesicles. (Leake, *Topography*, c. viii.; Beulé, *L'Acropole d'Athènes*; *Edinburgh Review*; July 1859.)

Prorogation (Lat. prorogatio). The continuance of the parliament from one sitting to another by command of the crown, whereby all business is suspended, and proceedings, with one or two exceptions, quashed. [PARLIAMENT.]

Proscenium (Gr. προσκήνιον, from πρό, and σκηνή, *a tent*). In Architecture, the frontispiece, or part in a theatre where the drop scene separates the stage from the audience; it is situated beyond the orchestra. In ancient theatres it comprised the whole of the stage.

Proscription (Lat. proscriptio, *an outlawry*). The most vindictive species of proscription was that introduced by Sylla when he wrested Rome from the hands of the Marian faction. It consisted in making out a list of persons supposed to be obnoxious to the state, and getting a sentence of condemnation passed, which made it unlawful to harbour them. By these measures thousands of citizens perished in the civil wars of Rome. The most celebrated proscription was that of the triumvirs, Octavius, Antony, and Lepidus, in which Cicero was slain.

Prose (Lat. prorsa oratio; from prorsus, adv., *direct* or *straightforward*). In Literature, all language not in verse. Prose diction, to be good, or even admissible, in ordinary criticism, must be conformable to the rules of composition as to style, cadence, &c.

Prosecution (Lat. prosecutio, *a pursuing*). In Law, the popular rather than legal name for the collective steps taken in order to bring an alleged offender to trial and conviction. The law of England differs from that of other countries in having no office analogous to what is termed in France *ministère public* for the prosecution of offences. At common law, therefore, and in the great majority of cases, the so-called *prosecutor* is merely the person injured by an offence, who in the first instance obtains a summons or warrant against the accused. In case of injury to the public, however, the Attorney-General is the recognised public prosecutor; and sometimes government originates proceedings in private cases of great importance or scandal: while informations for misdemeanours, in many statutable cases, are *prosecuted* by the informer.

Proselyte (Gr. προσήλυτος, *one who arrives as a stranger*). A term in use among the Jews after their connection with the Greeks, and applied to such foreigners as embraced their religion. These they divided, according to the common opinion, into two classes, distinguished by the terms *proselytes of the gate* and *proselytes of righteousness*. Of these the former were such as merely renounced idolatry, and believed in and worshipped the true God, receiving their name from being admitted within the first gate of the temple. The latter class were those who submitted to circumcision, and in every other respect conformed entirely to the customs of the Jewish people. Dr. Burton, however, thinks this distinction unfounded (*Lectures on the Eccl. History of the First Three Centuries*, i. iii.), and it probably is so as regards the Jewish national history,

having been introduced by the Rabbinical body from two to five centuries after the Christian era. (Smith, *Dictionary of the Bible*, s.v.)

Prosenchyma (Gr. προσεγχέω, *I pour still more upon*). In Botany, that form of cellular tissue the cellules of which taper to each end, and consequently overlap each other at their extremities. It is the first approach on the part of cellular tissue to the condition of woody tissue.

Proserpine. In Mythology. [PERSEPHONÊ.]

Prosody (Gr. προσῳδία). The science which treats of quantity, accent, and the laws of harmony, both in metrical and prose composition. In the Greek and Latin languages every syllable had its determinate value or quantity, and verses were constructed by systems of recurring feet, each foot containing a definite number of syllables possessing a certain quantity and arrangement. [FOOT.] The versification of modern European languages, in general, is constructed simply by accent and number of syllables. They have, therefore, no prosody strictly so called. The Germans, however, have laboured to subject their language to the ancient metrical system, but with indifferent success. (Hallam, *Lit. Hist.* pt. i. ch. i. p. 29.)

Prosopis (Gr. πρόσωπον, *a visage*). A genus of Leguminous plants of the sub-order *Mimosæ*, consisting of trees found in various tropical countries, and remarkable for having their pods filled in between the seeds with a pulpy or mealy substance. Thus *P. dulcis*, which, with several varieties often described as distinct species, is widely spread over Central and Southern America, is sometimes planted for its sweetish succulent pods, used for cattle-feeding, called Algarobo, after the Spanish Algarobo or *Ceratonia*, which it resembles in flavour. *P. spicigera*, in the East Indies, has also a sweet pod, there compared to the Algarobo. The pods of several species supply a large quantity of tannin. *P. glandulosa*, the Mezquit of Texas and the regions to the West, yields excessively hard and durable timber, and likewise affords a large quantity of gum resembling gum-arabic.

Prosopite (Gr. προσωπεῖον, *a mask*, from its deceptive or masked condition). A rhombic variety of Fluor Spar found at Altenberg in Saxony in brilliant dark blue crystals or in every state of alteration into Kaolin. It may be either a new dimorphous variety of Fluor, or pseudomorphous after Heavy-spar or Datholite.

Prosopography (Gr. πρόσωπον, *figure* or *person*, and γράφω, *I describe*). In Rhetoric, a word used by some critical writers to signify the description of animated objects.

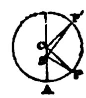
Prosopopœia (Gr. πρόσωπον, and ποιέω, *I make*). A figure by which inanimate objects or abstract ideas are personified, and addressed or represented by the poet or orator as if endowed with human shape or sentiments. Milton's famous digression of Sin and Death, in the *Paradise Lost*, is at once a prosopopœia and an allegory. [PERSONIFICATION.]

Prospectus (Lat.). In its most extended sense, this word is applied to the outline of any plan or proposal submitted for public approbation; but it is most usually confined to literary undertakings, in which it signifies an outline or sketch of the plan or design of a work, together with such other circumstances connected with the publication, &c., as it may be thought desirable to enlarge upon or make known.

Prostate Gland. In Comparative Anatomy, the prostate gland retains its single compact form in most of the Quadrumana, but is bifid in the Ruminantia. In the Rodentia and Insectivora it is resolved into numerous slender elongated cæcal tubes; in the mole it is remarkable for its periodical increase of size.

Prostates (Gr. προστάτης). The name given to the guardians of the foreign settlers at Athens, whose business it was to represent them in courts of law, and protect them from injury. [METŒCI.]

Prosthapheresis (a word made up from Gr. πρόσθεν, *in front of*, and ἀφαίρεσις, *subtraction*). A term used by the older writers on Astronomy to signify the difference between the true and mean motion, or the true and mean place of a planet, or the quantity which must be taken from or added to the mean anomaly, in order to get the true anomaly. Let P (or P′) be the place of a planet in its orbit, S the sun, C the centre, and A the perihelion of the orbit; the angle A S P is the true anomaly; A C P is the mean anomaly; and the difference between ASP and ACP is SPC, which is the prosthapheresis. If ACP be less than a right angle, SPC must be added to ACP in order to get the true anomaly; but if it be greater than a right angle the angle SPC must be deducted. The angle SPC is called by modern writers the equation of the *centre* or equation of the orbit.



Prosthesis (Gr. *an addition*). A figure of Grammar by which one or more letters are prefixed to a word; as in the common English participles, *be*loved, *be*reft, &c. [METAPLASM.]

Prostyle (Gr. πρόστυλος). In Architecture, a temple with a row of detached columns on its front elevation.

Prosyllogism. In Logic, a word sometimes used to signify a second syllogism, proving a former one; at other times in the same sense as enthymeme, viz. a syllogism of which one premiss is suppressed.

Protasis (Gr. literally *a stretching forth*). In Grammar and Rhetoric, every properly constructed PERIOD is said to be naturally divisible into two parts; of which the first is termed *protasis*, the second *apodosis*. In the ancient drama, the protasis was the exposition, usually contained in the first part of the piece, either by way of soliloquy or dialogue, serving to make known the characters and the plot to the audience.

Proteaceæ (Protea, one of the genera). A large natural order of arborescent, rigid Exo-

gens, of perigynous structure, belonging to the Daphnal alliance. They inhabit the hotter parts of the world, and are found growing in dry, sterile, stony, exposed places, especially near the sea-coast. They are distinguished by their irregular calyces having a valvate æstivation, by their apetalous flowers, by their anthers bursting lengthwise, and by their erect ovules. The genera *Banksia*, *Dryandra*, *Protea*, and *Grevillea* are cultivated for the sake of their beautiful foliage and flowers. The seeds of *Guevinia* are sold in Chili for the same use as hazel nuts with us. One of the larger timber-trees of New Zealand is the *Knightia excelsa*, a plant of this order.

Protection (Lat. protectio, *a covering*). In Political Economy, the indirect advantage which the legislature of any country gives to the sale of one or some among the productions of that country, with a view either to compensate the producer for some real or supposed disadvantages of a permanent kind under which he labours in competition with a foreign producer, or to aid in the developement of some nascent and imperfect manufacture. The means by which this advantage is accorded, is either by a duty levied on a foreign commodity, the home produce remaining duty free, or by a higher duty levied on the foreign than on the home produce, or by differential duties levied on the produce of foreign countries and colonial dependencies, or by the absolute prohibition of import. All these methods of protection have been adopted in this country at different periods of its economical history. An example of the first kind is to be found in the sliding scale of the old corn laws, and the shilling duty of the new; of the second, in the duties levied on foreign spirits as compared with the excise on home produce; of the third, in the colonial sugar and timber duties; of the fourth, in the bygone prohibition of the importation of Irish cattle. Most protective regulations have been eliminated from the English tariff; but all nations have conceived, and by far the largest number still conceive, that there is great wisdom, patriotism, and security in maintaining a protective system, despite the almost unanimous reasonings of economists, and the convincing experience of the benefits which result from an opposite policy. In the interval between ignorance and enlightenment as to the folly of protection, the practical refutation of the system is found in the encouragement and the sympathy given to the trade of the smuggler, a fraud on the revenue which administrations punish severely in their own case, and encourage studiously in dealing with foreign states. Thus, to encourage smuggling formed a necessary part of the English policy in retaliation for the Berlin edict; and so successful was this policy, that, notwithstanding Napoleon's influence over Europe in the first ten years of the present century, and the measures taken to enforce the decree, his own soldiers were clothed in English produce; and similarly the chief value of Gibraltar for many years was its convenience as a dépôt for smuggling goods into Spain. It is obvious that when the interest of a community is understood to consist in freedom of trade (and of this there can be no doubt as regards the export of its own products, whatever view may be entertained or enforced about imports), offences against the revenue, which are really wrongs inflicted on the tax-paying portion of the community, will be looked on with great leniency; a serious collision must needs arise between the public conscience and private interest, and a low tone of public morality will ensue. [SMUGGLING.]

It is observed that protection is accorded either by way of compensation or encouragement, and these are the two purely economical aspects of this kind of legislative action. But there are others which are social or political, and demand attention. It is sometimes alleged in defence of protection, that it enables a country to be more or less independent of foreign produce and foreign policy, and again that it tends to create a large social variety in the community. For instance, it is asserted that, if any country depends largely for any kind of produce upon supplies from foreign countries, it is in the power of such countries to starve or cripple the importing country by withholding the exportation, and (if needful) by compensating such members of the community as have produced in the hope of a foreign market. In the next place, it has been urged, that by encouraging, at least temporarily, the growth of some manufacture, the real advantage of variety of occupation will be secured to the community, and with it the benefits actual, or imaginary, of such a social reciprocity of feeling, education, and habit, as are supposed to arise from the due admixture of agricultural and commercial interests, and from the convenience of being provided, in case the cessation of any foreign supply takes place, with the home growth of the articles or utilities which might otherwise have been derived exclusively from external sources. Both these objections apply to imports. All civilised nations without exception desire to secure themselves a foreign trade, because unless they export commodities the accumulation of wealth is rapidly and permanently checked. Some of these arguments have been admitted and endorsed by eminent economists. A little attention, however, it is to be hoped, will be sufficient to show that both fears and benefits are equally imaginary.

In the first place, it may be observed, that the only commodities the prohibition of exporting which might affect an importing community, are grain and the raw material of clothing. Everything else could be dispensed with, and the prohibition, by destroying the trade of the producing country, would simply inflict an injury on the prohibiting community instead of a loss on the importing one in case the demand ceased. For instance, if the French or Spanish government were to prohibit the export of wine from their countries to England, the nation would either do without wine, or

draw its supplies from other sources, or, what is more likely, the wines of Spain and France would be sent to some port in some other country, and thence imported into England; and the result would be, that, first, the wine would be burdened with the cost of a circuitous carriage, and, next, the country which acted as a go-between would derive the advantage of lower prices from the producer, in consequence of the necessity which existed of exporting the produce, and the adoption of the only possible means of export. As regards the first necessaries of life, i.e. grain and the raw material of clothing, it is almost superfluous to say that they are very widely dispersed; that no country has a monopoly or sole production of them, except under very rare circumstances, and then only in one kind; and that therefore the inconvenience inflicted on the foreign market would be temporary, while the loss on the home producer would be lasting, because his market would be rendered uncertain. But, in effect, the practical refutation of this theory of dependence on foreign markets, and the risk of a prohibitory duty being laid on exports, lies in the fact that it has rarely been attempted, and has never been attended with the effect anticipated. As we have said before, it is in the first place contrary to the manifest interests of the producer, and is therefore unpopular and nearly certain to be evaded, either by smuggling or by transshipment, and in the next, other means and other sources are found to compensate the loss. Thus, during the French war, the English government prohibited the importation of saltpetre, and prevented that of sugar into France. The consequence was that nitre was procured from home sources, and the cultivation of beet received so powerful a stimulus in France as to make it a permanent object of industry. Similarly the cessation of the cotton supplies seemed to the leaders of the Confederate party in the Southern States of America so vital a question to English industry, that this country would be forced into a recognition of the Confederacy, if not into active aid. But though the local distress was great, the compensation supplied by other and analogous branches of manufacturing industry more than counterbalanced the loss of the cotton manufacture, and none of the political consequences which were anticipated ensued. But if so little resulted from the arrest of the cotton supply, the greater part of which was supplied from one region, how much less likely is it that any local prohibition of the export of grain should affect to any considerable extent the supplies derived from external sources. It is impossible to conceive such a state of things, unless every particular country which needed more grain than it could produce were at war with all mankind at once, and, to use an analogy which precisely represents such a status, were put into a state of siege by the whole world. So idle was the alarm which was frequently expressed during the time when the great economical struggle of twenty years ago was going on, as to the consequence of dependence on the foreigner. To depend on the foreigner as much as possible is to make the foreigner depend on oneself, for all nations are equally desirous to export their goods. Everybody who produces desires to sell, and the wider the market, the more certain is the purchase, the larger the aggregate profit of the transaction.

The argument that there is a social benefit in such a protective system as insures a diversity of occupations is a favourite mode of reasoning with the American protectionists, and is insisted on with great vehemence by Mr. Carey, almost the only economist of any reputation who has maintained every fallacy in favour of protection. But, in the first place, the argument starts with an unwarranted and unproved hypothesis, that benefit arises on purely social grounds from a diversity of occupations. Every nation must possess some manufactures, and it is certain that the manufactures of other countries must compete unequally (by reason of the charges of transport and the risks of a market—no trifling deductions) with those of home growth. A manufacturing class must therefore exist, and be the object of a *natural* protection. Besides, if one occupation is to be fostered on social grounds, why not all? If the ironmaster of Pennsylvania, and the cotton-spinner of New England, is to be protected, why not the author of Boston or elsewhere? If an American's body should be clothed only in fabrics of native work, why should an American's mind be enlightened by the labour of any other than an American's thoughts? To say that protection is to be afforded to certain branches of industry *only*, in order that the social benefits of every diversity of occupation should be secured, is an absurdity transparent to all except to the selfish instincts of particular producers. Protection on these grounds, to be just and consistent, should be accorded to all alike; and if everyone were thus protected, everybody would pay more for everything he needed, in other words he would get less for more labour; and even if some social advantage ensued from the stimulus given to plurality of occupations, still, as the protection must needs be accorded to the producers of the chief necessaries and conveniences of life (else the articles could be dispensed with, and the protection rendered nugatory), it may be doubted whether this is not more than compensated by the general loss inflicted on the community in the enhanced cost of such commodities. That the energy of American invention and industry stands in no need of any protective aid, and that therefore attempts to introduce prematurely any kind of occupation by legislative enactment are unnecessary, is proved incontestably by the extraordinary aptitude which the nation possesses of applying mechanical forces in aid or substitution of manual labour.

It remains to advert to the arguments by which protection has been defended in this

country, arguments which have been quoted summarily in the definition prefixed to this article. It is said, for instance, that the existence of a duty in foreign countries levied on articles produced in this, should be met by similar duties on imports. But the practical refutation of such a reciprocal loss has been supplied by manufacturers themselves, who have never during the last forty years ceased to importune the legislature to leave them free from such questionable aids. The most persistent claim, however, to protection was made by the landed interests, and the plea invariably alleged was the peculiar burdens laid on land, burdens which made it impossible for the farmer to compete profitably with the low prices of foreign produce. The result of this plea was the imposition of the CORN LAWS and the machinery of the sliding scale. The assertion that peculiar burdens are laid upon land, is a singular example of the facility with which a wholly baseless statement may gain credence when it is boldly and dogmatically repeated. Not only is it the case that there are no peculiar burdens upon land, but in fact the landowner has several distinct benefits accorded to him by the legislature. He did not till lately pay any succession duty, and even now real property pays at a far less rate than personal. He takes precedence of other creditors in the full payment of all debts due to him. His tenant's stock pays no insurance duty; and as insurance is part of the cost of production, and rent is all that remains after the cost of production is satisfied, he naturally gets added to his rent the tax which others pay for insurance. The duty on corn, although small, nevertheless affects all corn sold, as long as any is imported, and cannot raise on an average of years the price of all sold by less than a million and a half. He is able to borrow government money at lower than the market rate of interest. Poor rates, which have been shown to be really an insurance on labour, and therefore a deduction from wages, are paid by occupiers, i.e. by all alike instead of falling on employers of labour only. Highway rates, i.e. payments for the repair of roads, are, economically speaking, the machinery for supplying a necessary instrument to the agriculturist, i.e. the means of transit. These are also supported by all occupiers alike, and the last are maintained by tolls levied on the general public, the true wear of the road being the work of the farmer, who generally escapes the impost. It is not possible to advert to any tax which should be paid from land which is not, either wholly or in part, diverted upon some other kind of property or income. There is not the smallest warranty for asserting that land is affected by any peculiar burdens; while it is perfectly certain that, without any labour being expended upon it, land rises in value with the increase of population, and with the wealth and demands of the nation. But even if it had been the case that land had been exceptionally burdened, a protective system was the worst possible remedy for the inconvenience. It raised the price of one commodity, wheat, and dwarfed the price of all other agricultural produce. It insured a varying market for that which it professed to sustain, and thus inflicted the extremes of profit and loss on the producer, and it stereotyped a low market for every other thing which the farmer had to sell; for the greater part of the income of the greater part of the population being absorbed in the purchase of bread, a scantier margin was left for the purchase of meat, dairy produce, wool, and the other commodities which the farmer supplies. Thus we may confidently predict, that if at any time a great rise should take place in the price of bread, a great fall will take place in the price of all other farm produce, and the fancied gain on one side will be inconveniently balanced by a real loss on the other. No one is more interested in cheap bread than the landowner.

The remaining argument upon which protection is recommended, that it may support during its infancy some manufacture or branch of industry, not, as some American economists assert, for the benefit of society by encouraging all kinds of occupation, but as a means for developing in a new country a produce for which it is peculiarly fitted, and which it could not otherwise, as is presumed, have entered upon, has even been approved by Mr. Mill, *Principles of Political Economy*, book v. c. x. s. 1. The passage has often been quoted by protectionists in America and the colonies, as a complete apology for all such theories as have been put forward in those countries; and though it is not just to Mr. Mill, that, in spite of his strong protest against protection in the remainder of the chapter, his view should be cited as a vindication of protective extravagances, yet there is a dangerous latitude in his words, and an apparent authority is given to these delusive schemes.

Mr. Mill surrounds his case with cautions. The protection should be temporary, the industry should be suitable, and the aid should be granted only for such time as shall secure a fair trial. Mr. Mill does not say that the country must needs be young and rising, but considers this to be the most natural field for the experiment. He implies apparently that the community adopting protection for this limited period, should be equally able or perhaps better able to compete with another country in which the manufacture is already settled, provided this fair trial be accorded. It is plain indeed that, economically speaking, there is no difference between the case of a young country which begins an industry familiar to old countries, and that of an old which discovers the material for another industry not at present practised by itself, but occupied by one or two other communities. Newness does not lie in the country, but in the occupation followed in it. But, it may be asked, who is to judge of the time necessary for a fair trial of the

legitimate significance of a new set of conditions and of the suitableness of the industry? Every country, as has been said above, manufactures something. Every country has a natural protection for its own produce in the charge of carriage and the risk of the market contemplated by the importer. These appear to be the fairest set of conditions which can be supplied to any country for the adoption of a manufacture hitherto unknown, and to have been, historically speaking, completely sufficient for the growth of new industrial occupations in any community. Nor must we forget, that if protection be effectual, it not only taxes the purchaser of the protected commodity, but diverts the capital which could be employed for other products which need no protection. It not only inflicts a loss on consumers, but one on producers. And in young and rising countries, where the rate of interest is inevitably high, any diversion of capital from its natural channels, i.e. those in which it is, under existing circumstances, most productive, is a tax of the heaviest and most wasteful kind, and one which needs the most cogent reasons for its imposition—reasons little, if indeed at all, short of the urgent necessities of public safety.

There will probably never be wanting, in pursuance of Mr. Mill's hypothesis, plausible reasons for concluding that the conditions which he has alleged as justifying a temporary protection apply to many forms of industry, and for urging that public interests and even public safety are concerned in the aid to be given to special kinds of manufacture. But all these reasons, it may be submitted, are founded on particular instead of general interests. The developement of any branch of industry in countries or rather in localities for which it is most fitted, is a matter not only of national, but of what is far more important, human interests; and the general acknowledgement that a fair trial is to be sought only in letting things take their due course would do more towards breaking down the artificial barriers which separate the great families of the human race than any other conceivable means. It may unhappily be the case hereafter, as it has too frequently been the case hitherto, that motives of policy may be urged and may be employed in order to control and coerce industrial action, as well as to sow international jealousies. But the more thoroughly nations are taught to understand that their best interests are consulted when they depend on each other, and that for all economical purposes the civilised world is or should be but one community, the more certain is it that the harmony of purposes which would be fully effected were such a sentiment general, is being made complete. Political economy is not the wealth of a nation, but the wealth of all nations.

Some of the most ingenious illustrations of the fallacies of protection are to be found in the works of Bastiat, and perhaps among these none is more striking than that contained in a whimsical petition purporting to come from the various traders and manufacturers of artificial light, who are supposed to pray the Chamber of Deputies to grant them protection against the importation of that foreign produce, the light of the sun.

In this country, indeed, protection has not been abandoned, nor can it be said to have been abandoned so long as any privilege is given to any class of persons. That such privileges should be accorded is, of course, a question of public policy into which it is not possible to enter here. But the question is virtually decided as far as it relates to trade, agriculture, and manufacture, by the principle, now fully admitted, that any exceptional right, though not necessarily impolitic, though very possibly advantageous to the public interests, is nevertheless continually on its trial, and must needs vindicate its public utility before it can command present respect or secure itself ultimately from extinction. To have gained the acknowledgement of such a principle, is more important than the application of free trade to a few insulated cases.

Protectionist. In Politics, a name popularly given to those who maintain the principle of protection to native industry against that of free trade: in particular, to the party which opposed the repeal of the corn laws. The 'Society for the Protection of Agriculture' was dissolved in 1853 on Lord Derby's refusal to propose the restoration of those laws.

Protector (Lat. *a defender*). In English History, a title which has been three times borne by daring statesmen: 1. Richard, duke of York, in 1453, was appointed by parliament protector during pleasure. 2. The duke of Somerset, being constituted one of the sixteen executors of Henry VIII., obtained a patent from the young king, Edward VI., in 1548, constituting him protector, with the assistance of the other fifteen as councillors; but he enjoyed this dignity only a few months, and his loss of it was soon followed by his death. 3. Cromwell took the title of lord protector of the commonwealth of England, Scotland, and Ireland, on December 12, 1653, when the *Barebones Parliament* resigned its authority into his hand. His son Richard succeeded him in his title and authority, but was never formally installed protector.

Protein (Gr. *πρῶτος, first*). The azotised substance which forms the basis of albumen, fibrin, and casein, in which proximate principles it is combined with small proportions of sulphur and phosphorus. Different formulæ have been assigned to protein; that of Mulder is $C_{36}H_{27}O_{12}N_4$; but its existence as a distinct proximate principle is doubtful.

Protest (Lat. protestor, *I bear witness*). In Parliamentary Law, a privilege peculiar to the members of the upper house of parliament, of entering (by leave of the house always presumed) their dissent from a motion or resolution agreed to by a majority of the house, together with their reasons for dissenting. The paper embodying these reasons of dissent is called a

protest, and is entered on the journals. Protests, with the reasons, were first set down, according to Lord Clarendon, in 1641. [PARLIAMENT.]

Protestants. A general name applied to the various denominations of Christians which have sprung from the adoption of the principles of the Reformation in the sixteenth century. The term was assumed, in the first instance, by the reformers of North Germany, who, in the year 1529, formally protested against a decree of the imperial diet held at Spires, which ordained that the question between the parties should remain unsettled, some restrictions being laid upon the progress of the new opinions, until the calling of a general council, the time of which was left uncertain. The Protestants accordingly asserted that the decree was unfavourable and unjust to their party, and claimed the immediate summons of a lawful council, which they knew it was the interest of the papacy, under the circumstances, to delay. In the early period of the Reformation, the principal reformed churches were two, those of the followers of Luther and of Calvin, the partisans of Zuingli having become nearly identified with the latter. Since that time the number of subdivisions upon every point of doctrine and discipline has been infinite. The general bond of union, however, among all, continues to this day to be the assertion of private judgment, and the rejection of any infallible head of the church, or ultimate authority in pope or council. In modern Christendom, there are three principal divisions of Protestants: Anglicans, or of the church of England; Lutherans (North Germany, Scandinavia); Calvinists (Holland, Switzerland, France, Scotland). A rough calculation would make their relative numbers in Europe about fourteen, thirty, and twenty millions, the latter including some classes of dissenters in England.

Proteus (Gr.). In the *Odyssey*, this mythical being is described as an old man who tends the flocks (seals) of Poseidon, and rises at midday from the depths, to sleep upon the shore, surrounded by the monsters of the sea. His abode is variously placed in Pharos and Carpathos. Anyone wishing to learn his secrets might do so by catching him during his slumbers and holding him fast until he had exhausted his powers of transformation. A later version of the Trojan war represents him as taking Helen from PARIS, and leaving to him in her place a phantom which he carried to Ilion. Herodotus, rationalising this version, accepts it as the true account of the matter. [OANNES.]

PROTEUS. In Zoology, this name was originally and very aptly applied to a genus of Infusoria, which, during life, never for a single minute maintain the same form; this peculiarity is strikingly manifested in the common species called *Proteus diffluens*. The term was subsequently used by Laurenti to designate a singular amphibious reptile, peculiar to certain subterranean waters in Carniola, and which, like the American siren, retains the external gills, together with internal lungs or air-bags, throughout life.

Prothallus (a word coined from Gr. πρῶτος, *first*, and θαλλός, *a sprout*). In Botany, the term applied to distinguish the first results of the germination of the spore in the higher cryptogams, as ferns, adder's-tongues, horsetails, &c., in which the new plant springs from the impregnation of a cell in peculiar organs called *archegonia*.

Protheite or **Protherite.** A variety of Idocrase from Zillerthal in the Tyrol.

Prothorax (Gr. πρό, *before*, and θώραξ, *a breastplate*). In Entomology, this word signifies the first segment of the thorax in insects; by Kirby the term is restricted to the upper part only, or shield of that segment.

Prothyrum (Gr. πρόθυρον). In Architecture, a porch before the outer door of a house.

Protocol (from the Latin protocollum: a word made up from the Greek πρῶτος, *first*, and κόλλα, *glue*). The word *protocol*, in the French language, signifies the formulæ or technical words of legal instruments; in Germany it has been used to denote the minutes or rough draught of an instrument or transaction. In this latter sense the word has been borrowed by diplomacy, in which it signifies the original copy of any despatch, treaty, or other document.

Protogine. A porphyritic rock in which mica is replaced by talc or steatite. The granite of Mont Blanc is of this kind, and much of the Cornish china clay is obtained from the decomposition of similar varieties of porphyritic rock.

Protomorphic (Gr. πρῶτος, and μορφή, *shape*). The first stage of organised beings intervening between the fecundation of the germ and the first appearance of the typical or characteristic organisation of the species.

Protonotary (Low Lat. proto-notarius, or *first notary*). A title originally of the Byzantine empire. The apostolical protonotaries of the papal court are officers having precedence of the other notaries or secretaries of the Roman chancery; the papal *notaries participant* rank after bishops, but before abbots. In England, certain officers in the Courts of King's Bench and Common Pleas formerly had this title, but the offices are now abolished.

Protoplasm (Gr. πρῶτος, and πλάσμα, *a formed work*). In Vegetable Physiology, the term applied to matter deposited over the inside walls of a plant-cell subsequent to the formation of the cell itself.

Protopteri (Gr. πρῶτος, and πτερόν, *a feather*). An order of fishes in which the endoskeleton is partly osseous and partly cartilaginous; the exoskeleton as cycloid scales; pectorals and ventrals as flexible filaments; gills filamentary, free; no pancreas; swim-bladder as a double lung, with an air-duct; intestine with a spiral valve. The *Protopterus* or *Lepidosiren* forms an example of the order.

Protosaurus (Gr. πρῶτος, and σαῦρος, *a lizard*). The first fossil Saurian discovered,

and described by Spener in the year 1710, from the copper slates of Thuringia. The original specimen is now in the Royal College of Surgeons' Museum. It indicates the existence, during the period of the Permian strata, of a large, probably aquatic reptile, with a powerful neck and head, and sharpened teeth which enabled it to seize and overcome the struggles of the active fishes of the waters which deposited the old Thuringian *Kupferschiefer*.

Prototype (Gr. πρωτότυπος, *after the first form*). In the Fine Arts, the original pattern or model of a thing whereon are founded principles of imitation.

Protozoa (Gr. πρῶτος, and ζῶον, *animal*). A name synonymous with *Acrita* and *Oozoa*, and applied to the simplest living beings, or those which stand, as it were, on the first step of organisation.

Protractor (Lat. protraho, *I draw forth*). A mathematical instrument for laying down angles on paper, used in surveying, plotting, &c.

In its simplest form, the protractor consists merely of a semicircular limb of metal, divided into 180°, and subtended by a diameter, in the middle of which is a notch to mark the position of the centre. On placing this notch over the angular point, and laying the diameter along a given straight line, an angle of any number of degrees may be made by marking the point on the paper which coincides with the given degree on the limb, and joining this point with the centre, when the instrument is removed. The protractor is rendered more commodious by transferring the divisions to the edge of a parallel ruler.

For plotting surveys on a large scale a more accurate form of protractor is employed (Simms *On Mathematical Instruments*); the principle, however, is the same in all.

Proustite or **Light Red Ruby Silver-ore.** A sulpharsenide of sulphide of silver; composed, when pure, of 19·4 per cent. of sulphur, 15·2 arsenic, and 65·4 silver. It is a valuable ore of silver, and is found in Saxony, Bohemia, Spain, Mexico, Peru, &c. Named after J. L. Proust, the French chemist.

Provençal Language. The language of the TROUBADOURS—one of the Romance dialects which sprang up on the decline of the literary Latin. For the relation of the Provençal to other cognate dialects, see LANGUAGE.

Provençal Poetry. [TROUBADOURS; TROUVÈRES.]

Proverb (Lat. proverbium). A familiar saying, which has been variously defined. In point of form, there are two species of proverbs; one containing a maxim directly expressed in a concise and familiar style; the other, in which a maxim is expressed metaphorically, e.g. *honesty is the best policy*, or rather allegorically, e.g. *strike while the iron is hot*. In point of substance, proverbs are for the most part rules of moral, or, still more properly, of prudential, conduct.

In dramatic literature, chiefly French, the term has been applied to short pieces, in which some proverb or popular saying is taken as the foundation of the plot. They originated in the fondness of the higher classes of France for private theatricals, which became a sort of passion about the middle of the last century. Carmantelli was the most successful writer of proverbs at the time of their highest popularity. Those of M. Théodore Leclercq, at the present time, have met with considerable success.

Proverbs of Solomon, The. One of the canonical books of the Old Testament. According to the arrangement in its present shape, the first nine chapters form a species of introduction; those from the tenth to the twenty-fourth contain the proverbs ascribed to Solomon; and the remainder furnishes a kind of appendix; including the thirtieth and thirty-first, which contain the proverbs ascribed to Agur, the son of Jakeh, and to King Lemuel. According to Mr. Aldis Wright (Smith's *Dictionary of the Bible* s.v.) it is probable that the portion immediately following ch. xxii. contains a collection made by the learned men of the court of Hezekiah.

Provincia. Those countries were called by the Romans *provinces*, which, having been reduced under their power, were subjected to government by magistrates sent from Rome. The laws of a province were generally settled by ten commissioners, despatched from Rome in conjunction with the victorious general. In its modern acceptation, the term *province* signifies a grand division of a kingdom or state, comprising several cities, towns, &c., all under the same government, and usually distinguished by the extent either of the civil or ecclesiastical jurisdiction; in the latter case, the province, being a union of several dioceses, is subject to the archbishop.

Provision (Lat. provisio, *a foreseeing*). In Ecclesiastical Law (but not in use in England), the supply of an incumbent to a clerical office: consisting of *designation* and *collation*.

Provisions. In the Army. *Daily*: At home—¾ lb. meat, 1 lb. *best seconds* bread in barracks, or 1¼ lb. in camp. The stoppage paid by the soldier for this home ration is 4½*d*. a day. Abroad—1 lb. bread, or ¾ lb. biscuit, 1 lb. of meat, fresh or salt; at some stations special rations are issued for sanitary reasons connected with the climate; during active operations the officer commanding may increase the bread ration to 1½ lb. bread, or 1 lb. biscuit, and may issue wine or spirits.

The stoppage for a foreign ration is 3½*d*. daily. The families of soldiers abroad receive fractions of rations: wife, ½; child under 7, ¼; from 7 to 14, ½ ration.

The provision of forage consists daily of 10 lbs. oats, 12 lbs. hay, and 8 lbs. straw for each horse: issued to the soldiers without stoppage, but to the officers subject to a stoppage of 8½*d*. per ration.

From these arrangements it will be perceived that the sailor (who has equal pay) is materi-

ally better off than the soldier. The former is supplied gratuitously with all his provisions, while the latter receives a portion of them, having to make a small but covering payment for the rest, while he has also to provide other articles of diet from the remainder of his pay.

PROVISIONS. In the Navy. *Daily*: 1¼ lb. of biscuit or 1½ lb. of soft bread; spirits, ⅛ of a pint; sugar, 2 oz.; chocolate, 1 oz.; tea, ¼ oz.; when procurable, fresh meat, 1 lb., and fresh vegetables, ½ lb. When fresh provisions cannot be procured: salt pork, 1 lb. with split peas, ⅛ of a pint; or salt beef 1 lb. with flour 9 oz., suet ¾ oz., and currants or raisins 1½ oz. *Weekly*: oatmeal, ¼ pint; mustard, ½ oz.; pepper, ¼ oz.; vinegar, ¼ pint. These are all issued to the sailor free, i.e. without any stoppage from his pay.

PROVISIONS. In Prisons and Workhouses. The dietary tables of workhouses are generally uniform. At the present time, those of the metropolis are divided into several classes, which are provisioned at different rates. Thus the allowance of able-bodied paupers is generally 12 oz. of bread, 1½ pint of gruel, 1½ pint of soup or broth every day; the females having the same allowance as the males, except that two ounces less bread is served to them. Three times a week they have 5 oz. of cooked meat and ½ lb. of potatoes at dinner; on three other days, as stated before, 1½ pint of soup; and on one day 14 and 12 oz. of pudding respectively. When broth is not served at supper, they have 2 oz. of cheese instead. Aged persons have the same allowances, except that an ounce of butter and a pint of tea are supplied daily instead of the gruel, cheese, and broth of the able-bodied inmates. Children are supplied according to their age; the youngest, i.e. under two years, having bread and butter at discretion, and a pint of milk, 3 oz. of meat, and ½ lb. of potatoes daily. The amount increases as they grow older, and when they reach nine years they are generally rated as able-bodied women. Suckling women are allowed 3 oz. more meat on days when meat is served, but are otherwise treated as able-bodied women. Casual paupers are generally allowed 6 oz. of bread. When the paupers are employed in the service of the parish, and are therefore partially earning their support, their allowances are increased. The meat served is, of course, exclusive of bones.

A prison dietary is generally constructed on a progressive scale, the allowances for *short times* being much scantier than those served for longer periods of imprisonment. Thus the diet of a prisoner confined for seven days is a pint of gruel for breakfast and another for supper, and a pound of bread for dinner. A slight variation, but no material addition, is made for terms not exceeding twenty-one days, while those who exceed twenty-one days get small allowances of soup and meat thrice a week; those committed for longer periods still, get meat four times a week, and cocoa for breakfast and supper. The dietary for long terms is a little in excess of that served to paupers, both in quality and quantity. Criminals who commit prison offences are put on the sparest diet.

Proviso. In Law, a qualifying clause inserted in an instrument, commencing usually with the words *provided that*.

Provisors, Statutes of. Several statutes passed in the reigns of Edward I., Edward III. and Richard II. (35 Edw. I., 25 Edw. III., 27 Edw. III., 38 Edw. III., 3 Rich. II., 7 Rich. II. &c.) for the purpose of checking the claims of the popes to present to bishoprics and livings in England.

Provisory. In Politics and Jurisprudence, an agreement, law, or institution, is said to be provisory, which, established or entered into on account of immediate wants, requires further completeness of sanction to render it permanent, and subsists only *provided* it is so sanctioned.

Provost (contracted from Lat. præpositus, *placed over*). The title of the chief municipal magistrates of Scotland, equivalent to *mayor* in England. The chief magistrates of Edinburgh and Glasgow are styled *lord provost*. This title also belongs to the heads of some colleges in the English universities.

Provost Marshal. In the Army, an officer appointed in camp to preserve good order and discipline, to take charge of prisoners, and prevent crime. He is intrusted with authority to inflict *summary* punishment on any soldier or individual connected with the army, whom he may detect in the actual commission of any offence against order and discipline.

Provost of a University. [UNIVERSITY.]

Prow (Fr. proue, Lat. prora). The fore part of a ship, generally; and, in particular, the pointed beak or cutwater.

Proxenus (Gr. πρόξενος). In the ancient Greek states, a citizen who was intrusted with or took upon himself the charge of guarding the interests of the citizens of a foreign state, was called in the former case a πρόξενος, in the latter ἐθελοπρόξενος. The relation, however, was at first wholly voluntary, having arisen from the hospitium privatum or private ties of friendship between citizens of foreign states connected with each other. But when in two states, between which public hospitality had been established, no citizens came forward voluntarily to fill the office, then some one was formally appointed to it by the state. The early Spartan custom was to send a Spartan to the foreign state, to see to the interests of his countrymen, like the modern consuls; but generally the proxeni were citizens of the state to which the stranger came. Thus Alcibiades was the Spartan proxenus at Athens. The duty of the proxenus was chiefly to entertain ambassadors, and to mediate in any disputes which might arise between his own townsmen and the strangers for whom he acted as proxenus. [PROSTATES.]

Proximate Principles. Distinct compounds which exist ready formed in animals and vegetables, such as albumen, gelatin, fat,

&c. in the former; and sugar, gum, starch, resins, &c. in the latter, which are so called without reference to their ultimate composition.

Proxy (Lat. proximus). In Parliamentary Law, every peer, spiritual or temporal, can (by license, supposed to be obtained from the king) constitute another lord of parliament, of the same order with himself, his proxy, to vote for him in his absence. Proxies cannot be used when the house is in committee, nor in any judicial causes, nor can a proxy sign a protest. By an order of 2 Ch. II. (May, *Parliamentary Practice*, ch. xii.) no peer can hold more than two proxies. [PARLIAMENT.]

Prud'homme (Lat. homo prudens). In France, during the middle ages, municipal tribunals composed of citizens exercising a sort of conciliatory or equitable jurisdiction, as arbiters of disputes, inspectors of police, &c., were termed councils of *prud'hommes*. In 1806, a court of this denomination was re-established at Lyons by a law of Napoleon; and several others have since been created. Their principal office is the decision of disputes between masters and workmen in manufacturing towns.

Prune. [PRUNUS.]

Pruning (this word is connected by Mr. Wedgwood with the Old Norse prjon, the Scottish preen, or prin, *a pin* or *knitting needle*, from the notion of picking or arranging nicely with a pointed implement: *Dictionary of English Etymology*). In Arboriculture and Gardening, the art of cutting off parts of plants, and more especially of trees and shrubs, in order to strengthen those which remain, or to bring the tree or plant into some particular form calculated to increase particular products. Pruning therefore varies according to the kind of plant or tree to be pruned, and according to the object in view.

In the case of forest trees, the general object of pruning is to increase the quantity of timber in the trunk by diminishing the side branches, commencing at the lower part of the tree when it is quite young, and gradually advancing upwards as the tree increases in growth. In the case of hedges, the object is to produce a dense mass from the ground upwards, which is effected by shortening the side branches.

In pruning trees which are cultivated for the sake of their fruit or blossoms, the object is to thin out the branches so as to admit the light and air more freely to their leaves and blossoms, and to concentrate and increase the nourishment for the branches which remain. In the case of trees, or shrubs cultivated for the beauty of their shapes, whether natural or artificial, the object of pruning is to deprive the trees or shrubs of all those branches which deviate from or interfere with the natural shape, or with the form which is intended to be produced by art. In pruning with a view to produce fruit, it is necessary to know on what branches and buds the fruit is produced. In some trees, as in the peach, it is generally produced on the wood of the preceding year; in others, as in the apple and pear, it is generally produced on wood of two years' growth; and in the vine it is produced on shoots of the current year. The general effect of pruning on plants is to increase their longevity; since the tendency of all vegetables is to exhaust themselves, and, consequently, to shorten their duration, by the production of seeds. In the operation of pruning, the shoots are cut off close to the buds, or at a distance from them not greater than the diameter of the branch to be cut off; because, without the near proximity of a bud, the wounds will not heal over. In shoots which produce their buds alternately, the cut is made at the back of the bud, sloping from it, so that it may be readily covered by bark in the same or in the following year. This is readily done with a pruning knife, by a slanting cut, made at an angle of 45° with the direction of the branch; but, in the case of branches where the buds are produced opposite each other, either one bud must be sacrificed, or the branch must be cut off at right angles to its line of direction. Root pruning consists in shortening the principal roots so as to check over-exuberance of growth, and induce fruitfulness. It is practised chiefly with fruit-trees and ornamental flowering plants. The operation of pruning may in many cases be superseded by rubbing off, or pinching out, the leaf-buds, so as to prevent superfluous shoots from being produced.

Pruning Knife. A knife the blade of which has a straight edge, formed of well-tempered steel, and of no great breadth, with a narrow point, in order that it may be more readily introduced among crowded branches. Formerly, pruning knives were hooked at the point; but the cuts made by such knives had a tendency to crush the shoot, and leave a rough section, more readily injured by the air and water, and less likely to be speedily healed over. Such knives, when of a large size, were called *pruning hooks*.

Pruning Shears. Shears in which one of the blades moves on a pivot working in an oblong instead of a circular opening; by which means a draw cut is produced similar to that effected by a knife, instead of the crushing cut produced by common shears, which fractures the section left on the branch, and renders it liable to become diseased or to decay, instead of being covered over with fresh bark. Pruning shears are particularly adapted for cutting spiny or prickly shrubs, such as the different species of thorns, gooseberries, or roses.

Prunnerite. A calcareous Tufa, of a greyish-violet colour, found in Faroe.

Prunus (Lat. *a plum-tree*). A genus of *Drupaceæ* which includes, with the common Sloe and Bullace of our hedges, the apricot and plum trees of our gardens; though the apricot is sometimes referred to the genus *Armeniaca*. [APRICOT.] The sloe or blackthorn is a shrub whose upright stems are sought after for walking sticks, whose leaves are used to adulterate

tea, and whose fruit is employed in the manufacture of fictitious port wine. The Plum is a well-known and highly esteemed fruit, of which many varieties are grown. Some are employed for preserves, and for making the prunes of the shops. The prunes which come from Brignoles, in the South of France, are prepared from a variety called the *Perdrigon*. The neighbourhood of Tours is celebrated for the quantity of prunes which it furnishes. The German prunes are prepared from an oblong purple variety called Zwetsche, a Slavonian name which is spelt variously on the Continent. Damsons are plums well known and much used in this country for preserving, and so are the small round nearly wild sorts called *bullaces*. *P. myrobolana*, the Cherry Plum, which is a Canadian species, bears medium-sized heart-shaped fruit, in great abundance, and of tolerably good quality, but it is not equal to the European varieties.

Prurigo (Lat. *an itching*). An itching of the skin with or without the eruption of small pimples. The term is also carelessly applied to irritation of various parts of the body from other causes, as from vermin, worms, &c.

Prussian Blue. This pigment was accidentally discovered by Diesbach, a colour-maker at Berlin, in the year 1710. It is largely consumed in the decorative arts, and in dyeing, and calico-printing: it is used in making some of the varieties of what is called *stone-blue*, and is sometimes added to starch, though for this purpose, as well as for covering the yellow tint of paper, smalt or cobalt blue is preferable. Prussian blue is prepared of different degrees of purity, by precipitating solutions of peroxide of iron by ferrocyanide of potassium, various additions being made according to the purposes for which it is required.

Pure Prussian blue is obtained by adding a solution of ferrocyanide of potassium to persulphate of iron, thoroughly washing the precipitate, first with water slightly acidulated by sulphuric acid, and then with pure water, and ultimately drying it in a warm place. Prussian blue is of a peculiarly rich and intense blue, with a copper tint upon its surface: it is insipid, inodorous, insoluble in water, in alcohol, and in dilute acids, and is not poisonous. The alkalies decompose it into soluble ferrocyanides and oxide of iron; hence, as a dyeing material, it does not resist the action of soap. According to Chevreul, Prussian blue becomes white in the direct rays of the sun, but regains its blue colour in the dark. It is occasionally used in the composition of writing fluids.

Prussian blue is regarded as a compound of cyanogen and iron, but various views have been taken of its atomic constitution, as it has been considered to contain, or not to contain, the elements of water. When anhydrous, it contains seven atoms of iron and nine of cyanogen; or four atoms of iron and three of ferrocyanogen; but it is generally admitted that it cannot practically be obtained in this state, and that it always contains water, or the elements of water, which cannot be expelled without decomposing the compound; if so, it is probably a hydroferrocyanate of the sesquioxide of iron.

Commercial Prussian blue is generally contaminated with alumina, and often with chalk, plaster of Paris, and starch. *Turnbull's Prussian blue*, which is of a singularly brilliant tint, is the precipitate obtained by adding a solution of ferrocyanide of potassium to a solution of protosulphate of iron. When a solution of perchloride of iron is poured into one of ferrocyanide of potassium the precipitate which falls is insoluble in saline solutions, but after having been washed so as to deprive it of adherent salts, is soluble in pure water: it is known as *soluble Prussian blue*.

Prussic Acid. The composition and chemical characters of this acid are given under the head of HYDROCYANIC ACID. Prussic acid is frequently used medicinally as a powerful sedative and anti-irritant, especially to allay cough in phthisis, and to mitigate the spasmodic action in hooping-cough; but from its poisonous nature it requires to be employed with much caution. The antidotes for prussic acid, where it has been taken as a poison, are solution of chlorine, by which it is chemically decomposed; and ammonia, which combines with it, and acts as a stimulant. [CYANOGEN; HYDROCYANIC ACID.]

Prytanæum (Gr. πρυτανεῖον). The place of assembly of the Prytanes. In a Greek city the Prytanæum was the home of the community, and answered to the private homes of individual citizens. Hence a fire was always kept burning in the Prytanæum as on the hearths of private houses. In this building were entertained those citizens who by virtue of their office or for merit received the privilege of having their meals at the public cost. At Athens this was among the highest honours which could be conferred on anyone. Hence Socrates, when asked to adjudge his own penalty, named this as the recompense due for his past life and teaching.

Prytanes (Gr. πρυτάνεις). The Athenian senate consisted of 500 persons, fifty being elected from each of the ten tribes; each of these fifties took it by turn to preside with the title of Prytanes, having one-tenth of the year assigned to it; or, more accurately speaking, 34 days were allotted to each of the first four tribes, and 35 to the last six; the Attic year consisting of 354 days. Each fifty was again subdivided into five bodies of ten, which, when prytanes, took it by turns to perform the duties of proedri (πρόεδροι), seven days being allotted each. From these proedri, again, was chosen by lot an epistates (ἐπιστάτης) or president, whose office lasted one day.

Przibramite. Cadmiferous sulphide of Zinc from Przibram in Bohemia. The name has also been given to the capillary variety of Göthite, which is met with at the same locality.

Psalm (Gr. ψαλμός, from ψάλλω, *I sing*). A sacred song or hymn, originally accompanied with music. The book of Psalms is called, in

the modern Hebrew, *Thehillim* (*praises*). It is popularly ascribed to King David, by whom it may have been partly collected and to some extent composed. The Jews divide it into five books, ending with Psalm xli. lxxii. lxxxix. cvi. and cl. respectively. They, as well as all Christians, retain the number 150; but the divisions have varied. An apocryphal 151st is added in some Greek versions. The 119th and following Psalms to the 134th, called by some *gradual psalms*, or *psalms of the stairs*, a term of which various explanations have been given, are thought by Calmet and others to have been composed on the occasion of the deliverance from Babylon; possibly by Esdras, who is considered as the first collector of the Psalms; but they were at least partially used before, as early as the reign of Hezekiah. An attempt has been made to determine the respective ages of a large number of the Psalms by their employment of the names Elohim and Jehovah. (Bishop Colenso *On the Pentateuch* and *Book of Joshua*; Bishop Harold Browne, *The Elohistic Psalms*.) The latest Psalms, according to views now prevalent, are subsequent to the Babylonish captivity, and celebrate the rebuilding of Jerusalem.

Psalter. A book of devotion containing the psalms. (Palmer's *Origines Liturgicæ*, vol. i. p. 207.)

Psalterium (Lat.). The name of the manyplies or third cavity of the complex stomach of the ruminant quadrupeds, so called because it is occupied by numerous broad folds of membrane resembling the leaves of a book.

Psaltery (Gr. ψαλτήριον). A stringed instrument in use among the ancient Jews, by whom it was called NABLUM. It resembled, according to Burney, partly the lyre and partly the harp.

Psaturose (Gr. ψαθυρός, *fragile*). A sulphantimonite of silver, composed, when pure, of 70·36 per cent. silver, 14·01 antimony, and 15·63 sulphur. It is of a dark lead-grey colour inclining to iron-black, and is found at Schemnitz in Hungary, Freiberg in Saxony, and Zacatecas in Mexico. [STEPHANITE.]

Psellismus (Gr. ψελλισμός, *a stammering*). An imperfect articulation. Stuttering.

Psephoi (Gr.). A general name given to several things made use of by the Greeks in giving their suffrages, and in their computations, as small stones, shells, beans, &c. They were synonymous with the CALCULI of the Romans.

Pseudæsthesia (Gr. ψευδής, *false*, and αἴσθησις, *perception*). Imaginary or false feeling.

Pseudepigraphy (Gr. ψευδεπίγραφος, *with false inscription*). The ascription of false names of authors to works. This practice was carried to a great extent among the Christians of the earliest centuries. (Mackay, *The Tübingen School and its Antecedents*, part iii. 25.) Thus, many of the verses known by the name of Sibylline are evident Christian forgeries; and it is extremely difficult to distinguish the spurious works of the Fathers from the true. (See Gieseler, *Textbook of Eccl. Hist.*, 1st period, chap. iii. sec. 52, for a good section on Christian pseudepigraphy; Fabricii *Codex Pseudepigraphus*; Barbier, *Dict. des Ouvrages Anonymes et Pseudonymes*, contains a notice of most works falsely ascribed to their alleged authors in the French language.)

Pseudo-bulb. In Botany, an enlarged aërial stem, resembling a tuber, from which it scarcely differs, except in being formed above ground in the epidermis, being often extremely hard, and in retaining upon its surface the scars of leaves that it once bore.

Pseudoblepsis (Gr. ψευδής, and βλέπω, *I see*). There are various forms of false vision, some apparently dependent upon nervous irritation, others upon organic derangement. Specks, network, colours, and imaginary bodies floating or dancing before the eyes, distorted vision, double vision, are among the most common modifications of this complaint. They occur in plethoric as well as in debilitated habits, and are the consequence occasionally of intense study, of weakening evacuations, of debauchery, of hysteria, and of hypochondriasis: the treatment, therefore, which is required is very various. Attention to the stomach and bowels, local bleeding, camphor, ether, and other nervine stimulants, change of scene and occupation, varied exercise, are among the efficient remedies. When this condition is brought about by organic disease of the brain, the treatment must vary according to the nature of the lesion. In such cases, however, there is generally little hope of recovery.

Pseudodipteral (Gr. ψευδής, and δίπτερος, *with two wings*). In Architecture, a building in which the distance from each side of the cell to the columns on their flanks is equal to two intercolumniations; the intermediate range of columns which would stand between the outer range and the cell being omitted.

Pseudomalachite. Native phosphate of copper. [PHOSPHOROCHALCITE; PRASINE.]

Pseudomorphous Crystals (Gr. ψευδής, and μορφή, *form*). Substances found in crystalline forms not belonging to them, and being, as it were, casts of other crystals.

Pseudonym (Gr. ψευδώνυμος, *falsely named*). In Literature, a false or imaginary name assumed by a writer; more strictly, however, the former. Those who only assume a fanciful name, e. g. *Junius*, being more commonly ranked with *anonymous* writers.

Pseudopods (Gr. ψευδής; πούς, *foot*). A name applied to a tribe of Polygastric Infusoria (comprising Amœba and its allies), including those in which the body, by various contractions and changes of form, produces pediform processes.

Pseudoscope (Gr. ψευδής, and σκοπέω, *I view*). A name given by Professor Wheatstone to the stereoscope when employed to produce what he calls *conversions of relief*. These conversions may be produced in three different ways: (1) by transposing the pictures from one

to the other; (2) by reflecting each picture separately, without transposition; and (3) by inverting the pictures to each eye separately. The converse figure differs from the normal figure in this circumstance, that those points which appear most distant in the latter are the nearest in the former, and vice versâ. The *pseudoscope* consists of two reflecting prisms placed in a frame, with adjustments, so that when applied to the eyes each eye may separately see the reflected image of the projection which usually falls on that eye. The instrument being directed to an object, and so adjusted that the object shall appear of its proper size, and at its usual distance, the distances of all other objects are inverted; all nearer objects appear more distant, and all more distant objects nearer, and this constitutes the *conversion of relief*. The inside of a teacup appears a solid convex body. A china vase ornamented with coloured flowers in relief, appears to be a vertical section of the interior of the vase, with painted hollow impressions of the flowers. A small terrestrial globe appears a concave hemisphere; when the globe is turned on its axis, the appearance and disappearance of different portions of the map on its concave surface has a very singular effect. A bust regarded in front becomes a deep hollow mask. When regarded in profile the appearance is equally striking. A framed picture hung against a wall appears as if embedded in a cavity made in the wall. (*Athenæum* for 24 Jan. 1852.) [STEREOSCOPE.]

Pseudoscorpions. A family of Arachnidans, including those with an oblong body divided into several segments, with two or four eyes, and six or eight legs, as the book-crabs. (*Chelifer*.)

Pseudothyron (Gr. ψευδόθυρον). In Ancient Architecture, a false door.

Psidium. An extensive genus of South American trees belonging to the order *Myrtaceæ*. The most important species is the Guava-tree, *P. Guaiava*, which produces the well-known Guava fruits of tropical countries, a small tree, seldom growing more than fifteen or twenty feet in height. Several varieties are known, the two most common, distinguished by the shape of the fruit—*P. pomiferum*, with a round apple-shaped fruit, and *P. pyriferum*, with pear-shaped fruit—being sometimes described as distinct species. Both are natives of tropical America and the West Indies, whence they have been introduced into and become naturalised in India and other Eastern countries. They also produce very good fruit in our hothouses. Their fruits have a thin bright-yellow rind, and are filled with a pulpy yellowish or red flesh, which has a pleasantly acid-sweet flavour; but the pear-shaped variety is sweeter and more agreeable in a raw state than the apple-shaped, though both make very good jelly or preserve. Guavas are of too perishable a nature to permit of their being brought to this country in their natural state; but considerable quantities of guava-jelly and guava-cheese are brought by the West-India mail steamers. The wood of the Guava-tree has a fine close grain. *P. Cattleyanum*, the Purple Guava, probably a native of Brazil, yields abundantly deep claret-coloured fruit having a pale juicy flesh which is agreeably subacid.

Psilanthropists (Gr. ψιλός, *mere*, and ἄνθρωπος, *man*). A name sometimes used to denote those who believe that Jesus Christ was an ordinary man, and the son of Mary and Joseph.

Psilomelane (Gr. ψιλός, *bare*, hence *smooth*; μέλας, *black*; from its smooth or botryoidal form and black colour). A common ore of manganese, of very variable composition, probably only a mixture of the proto-peroxide Mn_3O_4, with pyrolusite MnO_4, and usually a little potash, baryta, and water. The principal British localities are Restormel Royal Mine, Cornwall; Upton Pyne, Black Down, Ashton near Chudleigh, and near Bideford, Devonshire; Brendon Hill Mine, Somersetshire; Drygill, Cumberland; Hartshill, Warwickshire; Leadhill, Lanarkshire; Old Kilpatrick, Dumbartonshire; Braeborough (*coralloidal*), and the Orkneys.

Psittacines (Parrot tribe). The name of a tribe of Scansorial birds, of which the genus *Psittacus* is the type.

Psittacus (Lat.; Gr. ψίττακος). The parrots belonging to the restricted genus *Psittacus* commonly have a strong bill, the head large without crest, the face covered with feathers, the body thick, the tail short and square. The prevailing colour is green. The common grey parrot is the *Ps. erythacus*, a native of Africa, which has been known to breed in Europe.

Psoas Muscle (Gr. ψόαι, *the muscles of the loins*). A large muscle upon the fore part and sides of the lumbar vertebræ. It bends the thigh forwards, and assists in turning it outwards.

Psophia (Gr. ψοφέω, *I make a noise*). A subgenus of storks, having a shorter bill than the rest, with the head and neck covered only with a kind of down, and the circumference of the eye naked. They frequent wooded regions, and subsist on grains and fruits. The best known species (*Psophia crepitans*) is a native of South America, and is remarkable for the ambiguous sound which it emits from time to time, and from which its specific name is derived. This bird is easily tamed by the Spanish settlers in South America, and is even taught by them to defend the common poultry from the rapacious birds, as a shepherd's dog guards his sheep from the wolves.

Psora (Gr.). The itch. [ITCH; PRURIGO.]

Psoralea (Gr. ψωραλέος, *scurfy*). A large genus of Leguminous plants, very widely distributed, and consisting of small shrubby or perennial herbs, usually having pinnate leaves, and spicate or racemose flowers. *P. corylifolia*, an East Indian herb, bears pods which have an aromatic taste; they are employed medicinally by the native doctors in India, and also yield an oil. The pods, under the name of Bawchan-seeds,

have been sometimes sent to this country for pressing. *P. esculenta*, a native of North-West America, produces tuberous roots, known as Indian or Prairie turnips, which form a great part of the food of the indigenous population, but when boiled are rather insipid. In Chili the leaves of *P. glandulosa*, there called *Culen*, are used as a substitute for tea under the name of Jesuit's Tea; but their infusion appears to be valued more for its medicinal properties than as an agreeable beverage, being a powerful vermifuge and stomachic; an infusion of the root is emetic and purgative. The plant has been introduced into Mauritius, where it has acquired a reputation as a remedy for diseases of the respiratory organs.

Psoriasis (Gr.). A rough scaly state of cuticle, sometimes continuous and sometimes in patches, generally accompanied by chaps or fissures.

Psorophthalmia (Gr.). An inflammation and ulceration of the eyelids attended by an itching sensation.

Psyche (Gr. ψυχή, *breath* or *soul*). In the later Greek writers the word *psyche* occurs as a personification of the human soul: and probably Apuleius was thinking of this personification when he related the following tale.

By her surpassing beauty, Psyche, the daughter of a king, excited the anger and jealousy of Venus, who sent Amor (Love) to inspire her with a passion for the most contemptible of mortals. But Psyche so charmed Amor that he fell in love with her himself, and taking her to some secret cave, visited her nightly, leaving her always before the dawn. Psyche had been warned by Amor against all attempts to find out who he was; but her jealous sisters told her that her lover was a hideous monster, and Psyche determined to learn the truth. Taking a lamp, she gazed at her lover while he slept, and saw before her the most beautiful of the gods. Amor, waked up by a drop of oil which fell from the lamp, rebuked her for her mistrust, and vanished. Then began the sorrows and wanderings of Psyche, who sought Amor in every temple till she came to that of Venus, who put her to a series of toilsome and degrading tasks, under which she must have died but for the love of Amor, who, though invisible, still consoled and cheered her. By his help she at last pacified the wrath of Venus, and, becoming immortal, was united with her lover for ever.

An examination of this tale reveals the fact that it was not invented by Apuleius, and that the several incidents which characterise it reappear in many Teutonic legends as well as in Hindu fairy tales. [VENUS.]

Psychology (Gr. ψυχή, *the soul*; and λόγος). In its larger acceptation, this word may be taken as synonymous with mental philosophy; but it is frequently used in reference to the lower faculties of the mind, and the classification of the phenomena which they present. All psychology is built on experience, either immediate or revived by the memory and imagination. But, in reflecting on our intellectual faculties, we discover in them certain laws, which, as soon as they are presented to us, we at once recognise as universal and necessary; certain conditions without the fulfilment of which we are sensible that no act of intellection could have taken place. This universality is something very different from the empirical truth, as a matter of fact, which we attribute to the laws of association, which are, indeed, universal, but which might, for aught we can see, have been different from what they are. Corresponding to this distinction, German writers have discriminated between a higher, or rational, and a lower, or empirical psychology; the first, that of Kant, who sought, in all our mental faculties, to determine that only which is necessary and immutable; the second, that of Hartley, who treats all our intellectual acts as alike objects of mere history, dependent for their validity only on the fact that they do really recur in such and such order. The psychology of Aristotle was of the latter description. He consequently regarded the science as forming one of the physical sciences, or those which are conversant with the contingent and changeable. Many pregnant psychological truths are discoverable in that philosopher's work on the soul; in particular, the doctrine of association owes its first enunciation to him. Among later writers who have made valuable contributions to the science may be enumerated Hobbes, Locke, Hartley, Sir Thomas Brown, Lord Mackintosh, and Professor A. Bain. [ASSOCIATION.] For earlier psychological theories, see Hallam, *Literary History*, part iii. ch. iii. [METAPHYSICS.]

Psychomancy (Gr. ψυχόμαντις, *a necromancer*). A species of divination, in which the dead were supposed to appear as spirits, to communicate the wished-for information.

Psychotria (a word coined from Gr. ψυχή, *life*, and ἰατρεία, *healing*). A Cinchonaceous shrub of tropical countries, one, of which, *P. emetica*, a native of Peru, yields what is called *Striated Ipecacuanha*. It is inferior to true Ipecacuanha, but a useful substitute for it.

Psychrometer. [HYGROMETER.]

Ptah. [PHTHAH.]

Pteris (Gr.). The genus of the common Brake or Bracken, a fern which is chiefly remarkable as being distributed in one form or other nearly over the whole world. This plant is the *Pteris aquilina* of botanists, and bears several other names in different countries. The rhizomes are sometimes cooked and eaten. They have the curious character when cut through obliquely of showing a figure resembling a spread eagle, or in some positions an oak-tree. The Bracken is a very useful plant for packing purposes, as well as for thatch and litter.

Pterocarpus (Gr. πτερόν, *a wing*, and καρπός, *fruit*). A family of large-growing trees, belonging to the Leguminous order, and yielding Kino and one sort of Rosewood. They

have pinnate leaves, and showy yellow blossoms, succeeded by flat nearly round or oval and somewhat one-sided pods. Gum Kino is obtained in India from *P. Marsupium*, and in Africa from *P. erinaceus*. Both are large trees, affording valuable hard timber, that of the former being extensively used in India in the manufacture of cotton-gins, while that of the latter is known in Western Africa as Rosewood. Kino is obtained by making incisions in the bark, from which the juice exudes and hardens into a brittle mass, easily broken into little angular shining fragments of a bright ruby colour. It is used in India for dyeing and tanning. Another species, *P. santalinus*, yields the deep red dyewood known as Red Saunders, large quantities of which are annually exported from India. Kino is also used medicinally as an astringent.

Pterodactyle (Gr. πτερόν, *a feather*, and δάκτυλος, *a digit*). The name of a genus of extinct reptiles, in which the second digit of the hand is of extreme length, and is considered to have supported an aliform expansion of the skin. It is divided into three subgenera, *Rampho-rhynchus*, *Dimorphodon*, and *Pterodactylus*.

Pterodon (Gr. πτερόν, and ὀδούς, *a tooth*). A genus of carnassial Mammalia which has been found in the eocene strata in France. The analogies of the *Pterodon dasyuroïdes* have led many palæontologists to ascribe it to the Sarcophagous family of Marsupials, near *Thylacinus*, but it exhibits strong traces of affinity to the typical miocene carnivore, *Hyænodon*.

Pteropods (Gr. πτερόν, and πούς, *a foot*). The name of a class of Molluscs, comprehending those which have a natatory wing-shaped expansion on each side of the head and neck.

Pterosauria (Gr. πτερόν, and σαῦρος, *lizard*). An extinct order of reptiles, characterised by the pectoral limbs being adapted for flight, through elongation of the antibrachium and fifth digit; by the pneumaticity of the skeleton; procœlian vertebræ; and a head large, with long dentigerous jaws. The principal genera of this order are given under PTERODACTYLE.

Pterygians (Gr. πτέρυξ, *a wing*). A name applied by Latreille to a group of Molluscs, corresponding to the Cephalopods and Pteropods of Cuvier, both of which have locomotive organs composed of wing-like expansions of the skin.

Pterygoda (Gr. πτέρυξ). Latreille has given this term to two small, hard, movable bodies, in the form of little elytra, directed backwards, and terminating at the origin of the wings. They arise from the two sides of the anterior extremity of the trunk, near the exterior base of the two first legs, instead of from the second segment of the trunk, like true elytra. They are present in Lepidopterous and Strepsipterous insects.

Pterygoid (Gr. πτερυγώδης, *wing-shaped*). This name is applied to processes of the sphenoid bone, which complete the osseous palate behind, and form distinct bones in the oviparous vertebrate animals.

Ptisan (Gr. πτισάνη, *barley-water*). A medicated drink prepared in France from the flowers of *Malva sylvestris*. It is also called Tisane.

Ptolemaic System. The astronomical systems of the Greek philosophers were based for the most part on theories for the truth of which no attempt was made to adduce the evidence of facts. But although they had thus a speculative character, they aided (sometimes not insensibly) the progress of a real science, as requiring the observation of phenomena in support of their several hypotheses.

The Pythagorean doctrine (the life and date of Pythagoras himself are shrouded in doubt and obscurity) asserted that the earth is not motionless in the centre of the universe, but that the central place is occupied by a mass of fire, which was mysteriously called the Altar of Nature and the Mother of the Gods. Round this centre, ten bodies moved in circular orbits, in the following order:, at the highest extremity the heaven containing the fixed stars, next the five planets, then the sun, then the moon, then the earth, and after the earth the ANTICHTHON. (Sir G. C. Lewis, *Astronomy of the Ancients*, 124.)

The first systematic explanation of the periodic motions of the planets came from Eudoxus of Cnidos (406–350 B.C.), who asserted that they were held in solid revolving spheres. This hypothesis of revolving spheres, which had been simple and intelligible enough while confined to the movement of the fixed stars, was made still more intricate by Calippus (a contemporary of Aristotle), who added seven spheres to the twenty-six of Eudoxus. With Aristotle as with Plato the earth was fixed at the centre of the universe, which, like Eudoxus, he held to be composed of revolving spheres, the motion of the bodies placed in these spheres being measured by their distance from the centre. But Aristotle saw that the motions of some of the planets were more intricate than those of the sun and moon, which he believed to be more distant from the external sphere. The solution of this difficulty he found in the conscious life of the stars, owing to which 'each orb accomplishes its circuit according to the best means at its command.' From the gravitation of matter to a centre he inferred the sphericity of the earth; and the comparative smallness of its size he gathered from the fact, that a slight change of distance to north or south changes the position of the fixed stars in those directions. His system was, in fact, substantially that which, under the name of Ptolemy, maintained its ground until it was finally set aside by the system of Copernicus. It was supported by the logic of Euclid, and in Galen's day the demonstration was as thoroughly believed as that two and two make four.

Against this system one remarkable protest was made by Aristarchus of Samos, who proposed a theory of the world exactly similar to that of Copernicus. [HELIOCENTRIC SYSTEM.] The date of Aristarchus is fixed by the testi-

mony of Ptolemy, who states him to have observed the summer solstice of the year 280 B.C. His theory is known to us only from secondary sources; but among these is the testimony of Archimedes, who could not fail to understand the hypothesis and to report it correctly. Archimedes was born 287 B.C.; and the theory of Aristarchus may have been published after he had reached his manhood. (Sir G. C. Lewis, *Astronomy of the Ancients*, 190.) From Archimedes, who rejected the theory, we learn that Aristarchus believed the earth to revolve in a circle, of which the sun was the immovable centre, the fixed stars being also motionless; that he assigned to the earth a rotation on its own axis; and that he explained the apparent annual motion of the sun in the ecliptic, by supposing the orbit of the earth to be inclined to its axis. (*Edinburgh Review*, July 1862, p. 94.)

The Alexandrian school of astronomy is pre-eminently distinguished by the names of Eratosthenes, Apollonius, Hipparchus and Ptolemy. Between the two latter there intervened a period of nearly 300 years, during which the practical astronomy of the Greeks made little progress. Hipparchus observed at Rhodes about 140 years B.C. This illustrious man appears to have paid little regard to the theoretical speculations of his contemporaries, but adopted the only method by which a correct knowledge of nature can be obtained, namely, assiduous and accurate observations. Among his important discoveries are the precession of the equinoxes; the length of the solar year; the eccentricity of the earth's orbit; the periodic time of the moon's revolution with respect to the stars, to the sun, to her nodes, and her apogee; the eccentricity and inclination of the lunar orbit. He invented the planisphere, determined the places of 1,080 stars, and was the first who introduced into geography the method of fixing the positions of places on the surface of the earth by means of their latitudes and longitudes.

The name of Ptolemy is still more celebrated than that of Hipparchus, although, as an astronomer, he occupies a far inferior rank. His principal astronomical discovery is the inequality of the moon's motion, technically called the *evection*; but his fame chiefly rests on his great work called *Syntax*, or *Composition*; in which he explains the apparent motions of the sun, moon, and planets, according to a hypothesis invented by Apollonius of Perga some centuries before, and which consists in supposing each of these bodies to be carried by a uniform motion round the circumference of a circle called the *epicycle*, the centre of which is carried uniformly forward in the circumference of another circle called the *deferent*. This second circle may be the epicycle of a third, and so on as long as inequalities remained to be explained; the earth occupying a position near, but not at, the centre of the last circle. This hypothesis is utterly demolished by a few accurate observations of the present day; but in the time of Ptolemy it served to explain all the deviations from circular motion then known, particularly the phenomena of the stations and retrogradations of the planets; and it was even of service to astronomy, by offering a means of reducing the apparent irregularities of the planetary motions to arithmetical calculation. Ptolemy's share of the merit belonging to the invention of this ingenious hypothesis consists in the determination of the proportion between the radius of the epicycle and that of its deferent circle, and between the velocity of the planet and the velocity of the centre of its epicycle. The Ptolemaic system continued in vogue till the revival of astronomy and the other sciences in the fifteenth century, when it gave place to theories founded on more enlarged views and more accurate observations.

Fourteen centuries elapsed between Ptolemy and Copernicus; and during this long interval astronomy continued nearly in the same state. The elements of the solar and lunar tables had indeed received many corrections; and various improvements in the methods of observing and calculating had been introduced, principally by the Arabs; but in respect of theory, no change had taken place. But an epoch had now arrived when men's minds could no longer be held in thraldom by reverence for ancient authority; and a spirit of investigation and enquiry had arisen, which produced the happiest results in all the departments of natural science. Copernicus, guided perhaps in some measure by the opinions of Pythagoras, but more by his own meditations on the planetary phenomena, and the comparison of the numerous observations accumulated by Purbach, Regiomontanus, and Walther, in the latter half of the fifteenth century, had the glory of establishing the system of the world on its true basis. In his great work, *De Revolutionibus Orbium Cœlestium*, published in 1543, he showed that all the apparent motions are easily explained by simply attributing a double motion to the earth; a diurnal rotation about its axis, and an annual motion about the sun. The doctrine of the earth's motion was opposed to the religious dogmas of the age, and accordingly the theory of Copernicus met with great resistance; but as observations now began to be greatly multiplied, and to be performed with greater accuracy, the evidences in favour of it daily acquired strength, and in a short time commanded universal assent among astronomers. Tycho Brahe, indeed, an excellent observer, and one to whom astronomy is under the greatest obligations, made an attempt to save the ancient prejudices; while he explained the phenomena by supposing the sun, accompanied by the planets, to perform a diurnal revolution about the earth. This system, however, on account of its physical improbability, never obtained many followers.

The next important step in astronomy was made by Kepler. By means of a laborious comparison and calculation of observations, Kepler discovered that the orbits of the planets

are not circles but ellipses, having the sun in one of the foci. He also found that the motion of any planet in its elliptic orbit is so regulated that the spaces passed over by a straight line drawn from the planet to the sun are equal in equal times; and that the periodic times of the different planets are in a certain given ratio to their distances from the sun. It is difficult to estimate the importance of these discoveries, either with reference to the amount of prejudice they overthrew, or their influence on astronomical theory. The circular and uniform motion of the celestial bodies was an axiom that had never been disputed. It was even admitted by Copernicus, who was obliged, in order to reconcile it with the observations, to suppose the sun placed at a little distance from the centre of each of the planetary circles. The elliptic motion was a proposition as bold as it was original; and, combined with the equal description of areas in equal times, led to the discovery of universal gravitation, and all the *sublime* results of physical astronomy.

Ptolemaites. A sect among the Gnostics, who maintained that the Mosaic Law came partly from God, partly from Moses, and partly from the traditions of the Jewish doctors.

Ptyalin (Gr. πτύαλον, *saliva*). A supposed peculiar animal matter obtained from saliva. It is insoluble in alcohol, and is said to be analogous to the vegetable substance termed *diastase*, and to convert starch into dextrine and glucose; it has therefore been termed *salivary diastase*. [SALIVA.]

Ptyalism (Gr. πτυαλισμός). An increased flow of saliva. Salivation.

Ptychotis (a word coined from Gr. πτυχή, *a fold*, and οὖς, *an ear*). An Umbelliferous genus of annual or biennial plants, one species of which, *P. Ajowan*, is much cultivated in Bengal, where its fruits, called *Ajowains*, are valued for their aromatic properties, and are used both for culinary and medicinal purposes.

Pubescent (Lat. pubescens, *hairy*). In Botany and Zoology, when a part or whole is covered with very fine short hairs.

Public Safety, Committee of. In the first French Revolution, this famous body, formed out of the Convention, April 6, 1793, was invested with very general powers to provide for the supposed welfare of the state, even the power of arrest and imprisonment being soon conferred upon it. After the downfall of the Girondist party [GIRONDISTS], this committee became the virtual government of France, by a decree of Dec. 4, 1793. Its members were, at this period, elected every month, but in general the members were re-elected. From this period its history is, in effect, that of the revolution. It appointed tribunals, composed of committees, invested with sovereign power to try offences against the state, over the whole country. It was in the committee of public safety that the opposition to Robespierre originated; but, on the overthrow of that personage, its powers were limited by the Convention; and, on the introduction of the new constitution of October, 1794, it became extinct along with the Assembly out of which it had been formed.

Public Schools. [SCHOOLS, PUBLIC.]

Public Weal, War of the. In French History, this name has been given to that struggle between the feudal aristocracy and the monarchy, which was ended by the defeat of the confederation entitled the League of the Public Weal, by Louis XI. The great feudal chiefs, especially of the houses of Foix, Albret, and Armagnac, saw with dislike and fear the growth of an absolute power in which they could have no share; but although the alliance into which they entered was nominally based on the interests of the people, and professed to redress their injuries, it had little or no popular support. It had become clear to the French that only under a strong government could they be secured against the violence of military ruffians and the lawless exactions of feudal chieftains. This discontent of the nobles came to a head, when the dukes of Brittany, Burgundy, Alençon, Bourbon, and the count of Dunois, leagued themselves under Charles duke of Berry, brother of Louis XI. and heir presumptive to the throne. But Louis contrived to prevent the interference of Edward IV. of England; the duke of Berry died suddenly at Guienne, not without suspicion that he had been poisoned by the king, and the less powerful vassals were rigorously punished, and the league finally crushed in 1472. (Hallam, *Middle Ages*, ch. i. part i.)

Publicans (Lat. publicani). The farmers of the public revenue of Rome. They formed two distinct classes: the farmers-general of the revenues, who were regarded as belonging to one of the most honourable grades of citizens; and deputies or under publicans of an inferior caste, whose reputation was very questionable. Hence, in the New Testament, the τελῶναι, or *publicans*, are almost always placed in juxtaposition with sinners. (Milman's *Hist. of Christianity*.) This term was also applied as a nickname to the ALBIGENSES.

Publicist. A term sometimes applied to writers on International Law.

Publilian Laws. In the ancient history of Rome, the name of three laws said to have been enacted by the dictator Q. Publilius Philo, B.C. 339. By the first of these laws the decrees of the plebs were to bind the whole community. By the second the senate was bound to give a preliminary consent to all laws put to the vote in the comitia of centuries. The third provided that one at least of the censors should be a plebeian. For the historical difficulties involved in the various accounts of these enactments, and of the earlier Publilian agitation assigned to the year 470 B.C., see Sir G. C. Lewis, *Credibility of Early Roman History*, ch. xii. sect. 32 and ch. xiii. sect. 22.

Pucha-pat. An Indian name for Patchouli. [POGOSTEMON.]

Puck (Old Norse puki, Welsh pwca: Wedgwood. Dr. Latham says that the Slavonic word bog, *deity*—whence the English

bogy—is 'almost certainly the same word as Puck; perhaps the root of *Bacchus*.' The connection of *bogy* with *bug* is attested by the expression *bug-bear*, to denote that which scares or terrifies). In Mediæval Mythology, the 'merry wanderer of the night,' whose character and attributes are depicted in Shakspeare's *Midsummer Night's Dream*. This celebrated fairy is known by a variety of names; as *Robin Good-fellow* and *Friar Rush* in England; and in Germany, as *Knecht Ruprecht*; but it is by his designation of Puck that he is most generally known both in England, Germany, and the more northern nations. He was the chief of the domestic tribe of fairies, or *brownies*, as they are called in Scotland; and innumerable stories are told of his nocturnal exploits, among which drawing the wine and cleaning the kitchen while the family were asleep, are the most prominent.

Pudding Stone. A name sometimes given to a peculiar variety of Conglomerate consisting of pebbles, rounded by the action of water, cemented together with a large quantity of silicious paste. Masses of such conglomerate are common in Hertfordshire. The pebbles within them bear a fanciful resemblance to the raisins in a plum pudding, but the stones are generally much larger than raisins.

Puddling. The method resorted to in iron works for the conversion of cast into wrought iron. It consists of two operations, the first being designed for the purpose of allowing the impurities of the iron to escape in the course of the refining process, while the second, which is the more correctly named process of *puddling*, consists in reducing the cast iron to the state in which it is susceptible of being drawn, hammered, and rolled into the shape of bars in the state of wrought iron.

Puerperal Fever (from Lat. puerpera). A fever attended by peritoneal inflammation, which comes on about the third day after delivery. The usual febrile symptoms are attended with great tenseness and tenderness of the abdomen; the milk disappears, and the bowels are usually affected by diarrhœa. It is most common in the autumn, and appears to be contagious. It is an alarming disease, and requires great promptitude and judgment in its treatment. It must be regarded as the result of contamination of the blood by animal poison generated in the system, and not as a local affection. This poison is probably produced by the decomposition of coagula or other material retained in the uterus. Bleeding, modified according to the circumstances of the case, calomel, saline sudorifics, and occasionally opium, to quiet pain and induce rest, are among the remedial means; but it often happens that great irritability of the stomach and bowels, or even incessant purging and vomiting, are predominant symptoms, and the fever assumes a typhoid character, in which case the system requires support from cordials.

Puffball. [LYCOPERDON.]

Pufflerite. The name given to the globular Prehnite of the Seisseralp in the Tyrol.

Pugging. In Building operations, the word *pugging* is used to denote the coat of lime and hair, or chopped straw, laid upon the sound boarding, in order to resist the transmission of sound between one story and another.

Pugil (Lat. pugillus). A quantity of anything which may be taken up between the thumb and two fingers.

Pugmill. A mill used by brickmakers for the purpose of thoroughly blending the materials. It is an upright cylinder, in the axis of which a shaft revolves having several knives projecting from it, arranged spirally round the arbor, so as effectually to knead and mix the mass of clay, which is finally forced through a hole in the bottom of the cylinder.

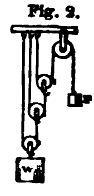
Puisne Judge (Nor. Fr. puisné, *younger*). The judges and barons of the Queen's Bench, Common Pleas, and Exchequer, with the exception of the chief justices and chief baron, are so called.

Pulley. In Mechanics, one of the six simple machines, or mechanical powers. It consists of a wheel, movable about an axis, and having a groove cut in its circumference, over which a cord passes. The axle is supported by a box or sheave, called the *block*, which may be either movable or fixed to a firm support.

Fig. 1.

A single pulley serves merely to change the direction of motion; but several of them may be combined in various ways, by which a mechanical advantage or *purchase* is gained, greater or less, according to their number and the mode of combination. The purchase gained by any combination is readily computed by comparing the celerity of the weight raised with that of the moving power, according to the principle of virtual velocities, which is alike applicable to all machines of whatever kind. In fig. 1, which represents a system where the several portions of the cord are parallel to each other, suppose the weight W to rise 1 inch, the two blocks would approach each other by that quantity, and consequently the length of cord connecting a single pair of pulleys would be shortened by 2 inches, so that the power P would descend 2 inches. Let the number of pulleys in each block be n; then, while the weight ascends 1 inch, the power descends $2n$ inches, and, consequently, when there is equilibrium, the power is to the weight as 1 to $2n$.

Fig. 2.



In the combination represented in fig. 2, the purchase is much greater. If n be the number of pulleys, it is readily seen that the relative velocities of P and W are as 2^n to 1, so that the power is to the weight as $1 : 2^n$.

In the combination represented by fig. 3, the mechanical advantage with n pulleys is still greater, and is easily proved to be as 1 to

$2^{n+1}-1$. This theoretical advantage, however, is in all cases greatly diminished by friction and the rigidity of the rope.

The last two combinations are of little, if any, use in practice, but various modifications of the first are common. *Smeaton's pulley*, or *Smeaton's tack*, as it is usually called, contains two rows of wheels, one under the other, in each block, and a single cord is made to pass over them in such a manner that the power and the weight both act in the same line with the centres of the two blocks, so that there is no tendency to twist. But this ingenious arrangement is open to several objections, the chief being the great amount of lateral friction of so many independent wheels. In White's pulley (fig. 1) the wheels in each block turn on the same axis, and consequently revolve in the same time; and they are of different sizes, their dimensions being so proportioned that a point on the circumference of any wheel moves with the velocity of the rope on that wheel. To effect this the diameter of the wheels in the upper block must be as the numbers 1, 3, 5, &c., and in the lower as 2, 4, 6, &c. Instead of separate wheels, the upper and lower blocks are cut in grooves in the above proportions, whereby the friction is reduced to that of one wheel in each block.

Fig. 2.

In the Great Exhibition at South Kensington, in the year 1862, an ingenious application of the system of pulleys was exhibited under the name of *Weston's patent pulley block*, which dealt with weights of from two to three tons, with the motive power of only one man. The sheaves of the blocks in this machine revolved in such a way as to offer a resistance to the motion of the rope, or chain, in case the power were suddenly withdrawn, so that the weight would remain suspended; and it required no hoisting crab, which is a serious drawback to the ordinary pulley blocks. There was no difference, however, in the principles regulating the arrangement or the sizes of the details of this machine from the principles generally observed.

Pulmogrades (Lat. pulmo, *a lung*; gradior, *I advance*). The name of a tribe of Acalephans, including those gelatinous species which swim by the contraction of the vascular margin of the disc-shaped body, where respiration also probably takes place.

Pulmonaria (Lat. pulmo). A genus of perennial herbs, often met with in old gardens, and remarkable for the spotted leaves of some of the species, from which cause, and some reputed but wholly imaginary value in lung diseases, it was called Lungwort. It is also called Jerusalem Cowslip.

Pulmonaries. The name of the order of Arachnidans including those which breathe by means of pulmonary sacs or lungs.

Pulmonates. The name of an order of Gastropodous Molluscs, including those which breathe air, to which the blood is exposed while circulating through a vascular network lining the internal surface of the bronchial cavity.

The order is subdivided into the *Pulmonata terrestris*, comprehending the Linnæan genera *Limax* and *Helix*, with *Clausilia*, Drap., and *Achatina*, Lam.; and the *Pulmonata aquatica*, comprehending the genera *Onchidium*, Buchanan; *Planorbis*, Cuv.; *Limnæus*, Lam.; *Physa*, Drap.; *Auricula*, Lam.; *Conovulus*, Lam.

Pulp (Lat. pulpa). In Botany, the juicy tissue found in the interior of plants. The term is applied in an especial sense to such tissue in fruits.

Pulpit (Lat. pulpitum). In Architecture, the raised part in a public building from which an oration is delivered. In the ancient theatres it was the higher part of the stage on which the musicians stood.

Pulque. The fermented juice of the *Agave*.

Pulse (Lat. pulsus, *a beating*). The pulsation of the arteries, depending upon the impulse given to the blood by the action of the heart. [Heart.] The pulse is usually felt by pressing the *radial artery* at the wrist, and the rapidity, regularity, and force of the circulation thus ascertained furnish an important criterion of the phenomena and progress of disease. The range of the pulse as to *frequency*, in a healthy adult, is usually between 60 and 80, but there are persons whose pulses rarely beat 60 times in a minute, and others, not out of health, in whom the frequency exceeds 80; the pulse, in short, is extremely capricious, and before any correct inferences can be drawn from it, the peculiarities of each individual require to be carefully considered. Slight mental affections, indigestion, irritability, and many other causes producing modifications of the pulse, do not admit of any general description. The terms *hard*, *full*, *soft*, and *wiry* pulse, are used to indicate other obvious modifications independent of the number of pulsations. The average rate of the pulse of a healthy infant is, for the first year, from about 120 to 108; for the second year, from 108 to 90; for the third, from 100 to 80; from the seventh to the twelfth year, the pulsations are about 70. When the pulse exceeds 140 beats in a minute, it is not easy to count it precisely, and to this it attains in some febrile diseases.

An *intermitting pulse* is by no means uncommon, and often produced by trivial causes: with many persons in perfect health the pulse will be subject to very extraordinary irregularities; and there are cases on record in which a person's pulse which has always intermitted in a state of health has acquired regularity on the accession of disease. The state of the digestive organs, more especially in gouty persons, has often a marked influence upon this condition of the pulse.

Pulse. Leguminous plants cultivated for their pods or seeds, such as the pea, bean, kidney-bean, &c.

Pulse Glass. A tube of about a quarter of an inch diameter and five or six inches long, with a bulb at each end, and about half filled with spirit of wine, care having been taken to expel the whole of the air before sealing the tube. When held in an inclined position, one of the bulbs being grasped in the hand, the ebullition of the included liquid causes the latter to rise and fall in the tube, or to *pulsate*.

Pulvilli (Lat.). In Entomology, the cushions of short hairs very closely set, or a membrane capable of being inflated, or very soft and concave plates, which cover the underside, or their apex, of the four first joints of the manus or tarsus, and sometimes even of the ends of the movable spines situated at the apex of the *tibia*, which act so as to produce a vacuum, and enable the insect to suspend itself, or walk against gravity.

Pulvinated (Lat. pulvinar, *a pillow*). In Architecture, a term used to express a swelling in any portion of an order, such, for instance, as that of the frieze in the modern Ionic order.

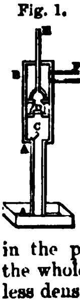
Pulvinus (Lat. *a cushion*). In Botany, the cushion-like enlargement seen at the base of the leaves, or at the apex of the petioles in certain plants.

Pumice (Lat. pumex). A porous rock obtained only in volcanic districts, and produced by the action of gases on materials melted by volcanic heat. It is light, spongy, and fibrous, of an ashy grey colour, and extremely rough to the touch. It is somewhat largely used in the arts, owing to its uniform roughness and the absence of irregularities of hardness. It can only be regarded as a variety of trachytic lava.

Pump (Ger. pumpe, Fr. pompe). A machine for raising water. Though the forms under which this useful engine is constructed, and the mode in which the power is applied, may be modified in an infinite number of ways, there are only four which can be considered as differing from each other in principle. These are the *sucking pump*, the *forcing pump*, the *lifting pump*, and the *centrifugal pump*: so called from the manner in which they act.

The *sucking pump*, or common household pump, is an apparatus of which the principle and construction will be evident from the annexed figure. A A is a pipe of any convenient length, the lower end of which reaches below the surface of the water in the well or reservoir; B is a barrel, generally of greater diameter than the pipe; C a valve opening upwards; D a piston moved by the rod E: in this piston there is also a valve opening upwards. When the piston is raised, the air in the barrel between the valves is expanded, and its tension consequently diminished; the pressure of the air in the pipe, therefore, opens the valve C, and the whole air in the pipe and barrel becomes less dense. In this state the atmospheric pressure on the surface of the water causes it to rise in the pipe, until the tension of the confined air becomes equal to the pressure of the atmosphere. On again depressing the piston, the valve in it opens, and the air passes through it from the barrel as it descends; but the valve C is closed by the downward pressure, and the volume of water which has entered the pipe remains. On again raising the piston, the same effect is repeated, and an additional quantity of water enters the pipe. Thus, by the alternating motion of the piston, a column of water is raised in the pipe until it reaches the piston when at the bottom of the barrel, and the whole of the air below it has been excluded. On raising the piston when the water has reached it, the fluid will be compelled to follow by the pressure of the atmosphere on its surface in the well. When the piston is again depressed, the water flows through the valve in it, and ascends into the barrel, and by the succeeding strokes of the piston is lifted up until it reaches and flows out of the spout F.

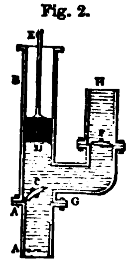
Fig. 1.



Although in theory the limit of the height to which water may be raised by the sucking pump, from the surface of the fluid in the well to the highest position of the movable piston, is about thirty-four feet (the height of a column of water which balances the pressure of the atmosphere), it is not found practicable, with pumps of the ordinary construction, to raise it more than about twenty-eight feet. The difference arises from the difficulty of making the apparatus absolutely air-tight.

The *forcing pump* is represented in fig. 2. The piston-rod E D is attached to a solid plunger D, adjusted to the cavity of the barrel. A pipe G H, furnished with a valve F, opening outwards, communicates with the barrel at G. On elevating the plunger D, the water will ascend through the valve C, in the same manner as in the sucking pump, till the barrel is filled to D. Now, when the plunger is depressed the valve C will shut, and the water between D and C be forced through the valve F into the pipe G H. When the plunger is raised, the valve at F shuts, the pressure on its under side being removed, so that the water which was forced into the pipe by the previous stroke cannot return into the barrel. At the next stroke of the piston more water is again forced into the pipe, and so on till it is raised to the height required.

Fig. 2.

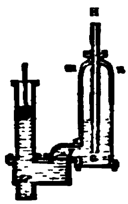


In this pump the pipe A A may be dispensed with, and the barrel B immersed in the reservoir; in which case the action of the pump is independent of the atmospheric pressure, and could be maintained equally well in a vacuum.

In order to produce a continued stream through the pipe G H, an air vessel *m n* may be attached to the lateral branch above the

valve F (fig. 3). The pipe G H reaches nearly to the bottom of the air vessel; and when the water has been forced into the vessel by the action of the pump, until it reaches above the lower end of the pipe at G, it is evident that, as all communication is then cut off with the external atmosphere, every additional quantity of water thrown into the vessel will tend more and more to compress the air within, which, acting by its pressure on the surface of the water, forces it through the pipe G H in a continued stream.

Fig. 3.



The *lifting pump* is represented by fig. 4. The barrel of the pump is immersed in the water and fixed to an immovable frame. The piston with its bucket and valve C, opening upwards, is attached at E to another frame, G H I K L, consisting of two strong iron rods, H I and L K, which move through holes in the frame-work to which the pump is fixed. An inclined branch M N, either fixed to the top of the barrel, or movable by means of a ball and socket, is fitted exactly to the barrel, and furnished with a valve at M. Suppose the barrel immersed in the water to a certain depth: if the piston frame be now thrust down by the handle at G, the piston will descend, and the water be forced by its upward pressure through the valve C, so as to maintain the same level in the pump as in the well. But when the piston frame is elevated, the valve C will shut (as shown in the figure), and the water above C be *lifted up* with the piston, and forced through the valve M into the branch M N, from which its return will be prevented by the shutting of the valve M when the piston descends.

Fig. 4.

In each of these different kinds of pumps which have been described, the total effort required to work the machine, independently of friction, is equal to the weight of a column of water, the base of which is equal to the area of a section of the working barrel, and the altitude equal to the distance between the surface of the water in the reservoir and the point to which it is raised. In the sucking pump the whole of this effort is expended in raising the piston; in the forcing pump, one part is expended in raising and the other in depressing the piston, and it is advantageous to dispose the machinery so that these two parts shall be nearly equal. In small pumps for domestic purposes, the strength of man is usually employed as the moving power; but in raising water from great depths, as the bottoms of mines, the steam engine is applied to this purpose. [Fire Engine.] For an account of the mechanism of different kinds of pumps, see Gregory's *Mechanics*, vol. ii.; the *Aide-Mémoire of the Military Sciences* may also be consulted, both for the bibliography and the description of the different kinds of pumps.

The *centrifugal* or rotary pumps are those in which a rectilineal vertical motion is communicated to the water to be raised by means of a wheel, bearing a series of fixed arms rotating at a high velocity in a close drum, and receiving its supply through apertures in the side of the drum close to the axis. The shape of the arms has a very material influence upon the useful effect of these pumps; and, after many experiments, it has been found that the most advantageous form to be given to them is to curve them backwards to the direction of the movement, so as to form a tangent to the circumference of the wheel at the points where they intersect it. Amongst the most valuable forms of these centrifugal pumps for drainage purposes, are those manufactured by Mr. Appold, or by Messrs. Gwynne & Co.; and perhaps it may be desirable to add that the latter work with the smallest loss of power compared to the useful effect, with small lifts: Appold's pumps, however, present more satisfactory results when higher lifts are required. All these engines are inferior to the best forms of force pumps when large volumes of water have to be raised to great heights; and their use would appear, in their present forms at least, to be most advantageously limited to lifts of about thirty or forty feet vertical as a maximum. (*English Cyclopædia, Arts and Sciences.*)

The *chain pump* sometimes used in ships of war consists of an endless chain moving over a wheel on the gun deck, which is turned round by winches, and over a roller in the pump-well, having saucers or flat circular pistons at certain intervals. Near the pump-well, on the side on which the chain on turning the winches ascends, are a few feet of pipe; through this the saucers raise the column of water, which, being lifted over the upper orifice of the pipe, falls into the cistern, and thence into the waste-pipe, called the *pump-dale*, which carries it overboard. The descending portion of chain falls through another case called the *back case*. Chain pumps, in large ships, throw out a ton a minute.

Pumpernickel. The name of a species of rye bread peculiar to Westphalia. It forms the chief food of the Westphalian peasants, but is regarded as a great delicacy in other parts of Germany, whither it is exported in large quantities. The loaves sometimes weigh 60 lbs. The term is said to be of French derivation, and to have originated in a French soldier having rejected the bread with disgust, exclaiming, 'C'est bon pour Nicolas:' i.e. for his horse.

Pumpkin. The *Cucurbita pepo*, a large kind of Gourd, cultivated as an esculent.

Pun. A play upon words, the wit or point of which depends on a resemblance between the sound of two or more words, which have different, and perhaps opposite, meanings. [Paronomasia.]

Punch (Ital. punzecchiare, *to punch*, from punzone, *a goad*). The process of producing a

hole in a piece of metal by direct pressure is called *punching*. This process can be applied only to the malleable metals, such as lead, zinc, copper, iron, &c., cast iron or bronze being liable to break or to produce a ragged edge, if so treated. The action of piercing the plates by means of a drill must not be confounded with punching.

Puncheon. In Architecture, a short post; also the small quarters of a partition, above the head of a door.

PUNCHEON. A measure of capacity for liquids, containing 84 gallons or one-third of a tun.

Punctate (Lat. punctum, *a point*). In Zoology, when a part is beset with many points or minute impressions, which do not perforate the surface.

Punctuation. In Printing and Writing, the dividing words, propositions, or sentences from each other by means of certain marks or points, designed to facilitate the apprehension, or to regulate the enunciation, of written language. Points or stops are said to have been first used by Aristophanes, the Alexandrian grammarian; but the modern system of punctuation is due to Aldo Manucci (Manutius), a learned printer, who lived at Venice in the fifteenth and sixteenth centuries. The marks most commonly in use are: 1. The comma (,), which is placed between the less important divisions of a sentence or passage; as, for instance, before and after qualifying propositions or clauses; between single words not connected by conjunctions; before conjunctions which unite sentences, &c. 2. The semicolon (;), which distinguishes the longer or more important members of a sentence; as when the latter part is an inference from, or qualification, explanation, or illustration of, the former. 3. The colon (:), which is chiefly used to distinguish such members of a sentence as are themselves divided by semicolons into two or more principal parts. 4. The period or full stop (.), which stands at the end of a complete sentence. Besides these may be enumerated the note of interrogation (?) or enquiry; of exclamation (!), expressing admiration, endearment, or any considerable emotion; the parenthesis ( ), used when a clause is inserted which interrupts the progress of the sentence; with other marks, either less commonly used, or for the use of which the rules are less easily defined.

Punctum Caecum (Lat.). That part of the retina of the eye immediately about the spot at which the optic nerve unites with it is found experimentally to be totally insensible to the stimulus of light, and hence it has been called by writers on Optics the *punctum cæcum*.

Pundit. [PANDIT.]

Punic Language. The language of the ancient Carthaginians. It was a Phœnician dialect, and substantially the same as the Hebrew.

Punic Wars. The name given to the celebrated contests in which the Romans and Carthaginians were engaged for more than three centuries, and which finally terminated in the destruction of Carthage. The first commenced A.C. 264, and ended A.C. 241; the second lasted from A.C. 218 to A.C. 202; the third from A.C. 149 to A.C. 147, ending with the destruction of Carthage.

Punic Wax. In Painting, the vehicle used by the Greek painters in their wax and encaustic pictures, &c. Punic wax, says Pliny (*cera Punica*), was the ordinary yellow wax purified and bleached, by being boiled three times in sea water with a little nitre, the water being changed each time: it was then taken out of the water, covered with a thin cloth, and placed in the sun to dry. So prepared it was mixed with various colours and made into *ceræ* fit for the painter's use, and it was also employed in varnishing or polishing.

Punica (Lat. punicus, *red*). The genus of the Pomegranate, which is called by botanists *P. granatum*. The fruit is peculiar, being composed of two whorls of carpels placed one above the other. It is the produce of a tree growing in Northern Africa and Western Asia, and varying from fifteen to twenty-five feet in height. The flowers are usually scarlet and yield a red dye. The fruit is greatly valued in warm countries on account of its cooling and refreshing pulp. Many varieties are grown, some being sweet and vinous, and others acid or of a bitter astringent taste. It is generally about the size of the fist, and has a tough leathery rind of a beautiful deep golden colour tinged with red. The rind, especially that of the bitter kind, contains a large quantity of tannin, and is used for tanning the celebrated morocco leather. Some double-flowered varieties are very beautiful garden shrubs.

Punicin. A peculiar principle having the appearance of an oleo-resin obtained from the root of the Pomegranate, *Punica granatum*.

Punishment (Lat. pœna, *punishment*). In Jurisprudence, the infliction of suffering, under legal sanction, upon those who have violated the law.

It is undoubtedly true, that both in legislation and in public opinion respecting punishment, the *vindictive* theory which considered it as a retribution for crime, and to be governed by our moral feelings of indignation against the offender, has far too generally prevailed, and that the primary end, the interests of society, has been overlooked. But it may perhaps be doubted whether the present course of opinion does not run too exclusively in the contrary direction, and whether they who adopt the common formula, that 'the object of all punishment is the prevention of the offence in future,' have reflected on all the consequences of that position.

For instance, it is the common practice in this country, as well as in others, to connect the administration of justice with the enforcement of the tenets of religion and morality. In passing sentence, wherever there is any peculiarity in the case calculated to call forth such remarks, the judge rarely fails to comment on

the moral deformity of the act; not merely in its tendency to injure society, but subjectively, as showing moral depravity in the person committing it. (Lord Russell, *The English Government and Constitution*, ch. xxiv. 1865.) The solemnities of public worship which form part of the ceremonial; the public harangues of the judges (as, for instance, in the English custom of charging the grand jury); the language in which the jury is commonly addressed, both by the judge and the advocates; all these seem based on the assumption, that the moral quality of acts is one of the matters to be brought under their consideration. But if the judge has really no concern whatever with that moral quality, and is simply there to see that society may be guarded, as far as possible, from exposure to material injury by fraud or violence, it may be thought that all these ceremonies are out of place, and that they can be defended only as politic devices, employing the machinery of religion to aid in deterring offenders from the commission of crime, or as concessions to popular ignorance. And it is certain that in such a case it would be far better to abolish them altogether, as leading the mind to dwell on that view of the object of punishment which it is the purpose of Bentham and his school to extirpate, as irrational and false.

Again, in popular estimation, the moral atrocity of an offence is one of the elements in the correct measure of punishment. On whatever ground philosophers may object to sanguinary laws, this conviction has retained its hold on the public mind. In the case of forgery, for example, the feeling of the majority triumphed in the end over the severity of the law, not so much because the penalty was thought disproportioned to the injury inflicted on society or to the importance of repressing the crime, as because it was thought not to deserve it in a moral point of view. Now all such expression of sentiment, on the theory in question, is founded on a wrong principle; and the writers who adhere to it are forced to admit this feeling as a disturbing cause, preventing the right doctrine from being fully carried out; they are forced to admit, as part of their definition of a good punishment, that it shall not be such as to shock the popular notion of moral justice —an admission which they can make consistently only by maintaining that punishments which shock popular notions of justice and equity are likely to multiply offences or aggravate their character, and so to interfere with the real interests of society.

That the interest of society is the first object of punishment must be conceded on all hands. That the specific object of preventing the offence from being committed is a very important part of that general object, probably by far the most important, may also be conceded. But it is a further question, whether the general object does not comprehend other particular objects also; and whether a punishment which should answer in the highest degree the advantage of repressing that particular offence, or class of offences, might not be imperfect notwithstanding.

This question can be solved only by deciding the great preliminary difficulty of political science, in which so many others are involved; whether the ruling power which we call the state, or society, or the legislature, has or has not any *moral* authority. Those who conclude that it has nothing to do beyond preserving the personal security and property of individuals, of course deny that it has any. But those who believe that it has, also, what may be termed paternal power, and is intrusted by Providence with the maintenance of religion and moral principle, must, consistently, admit that there may be a moral object in punishment beyond the mere prevention of the offence, unless they maintain that the moral authority of the state is to be exercised not in punishment but in prevention, as by education.

And it must be observed in passing, that those who do hold the state to possess such a moral authority, and have such moral duties imposed upon it, need not, therefore, hold those to be its principal objects. It may very well be that the primary object of the association of men in a political body is security and self-defence; yet that association may have other ends not inconsistent with this. And although those other ends are in themselves incomparably the most important, it does not at all follow that they are the most important as regards the state. When men enter into a particular contract with each other, their mutual duties under that contract are primarily those connected with the object of that contract; they may have other and more important mutual duties, which yet, as regards that contract, are secondary. No religious man will deny that the connection of master and servant involves some duties of a very exalted character; but the principal object of that connection is, nevertheless, the rendering of service in lieu of a remuneration.

It must, however, be remembered that the theory of the moral vocation of the state does not necessarily justify retribution as an object of punishment. No one can apportion retributive justice who cannot judge of the motives of actions. The moral authority of the state, even by those who have carried its divine character to the highest point, has only been likened to the paternal; and no father has the right to chastise a child by way of retribution. He has no right to punish at all, except with a view to reformation. Omitting this mistaken end, the real objects of punishment may be classed as follows:—

1. The interest of society; which must be subdivided into—

i. Its security from the injury to person or property occasioned by the crime.

ii. Its moral and religious improvement.

2. The reformation of the offender. This is admitted as one of the ends of punishment by all writers; but Bentham and his

followers regard it as such only so far as it conduces to the security of society by preventing the repetition of the offence; those who embrace the other view regard it as an end, both on this account and also as the fulfilment of the duty of the state towards the offender himself. Considered in either view, it is clearly a secondary object only, the good of society being the first.

The security of society is attained by punishment in four ways:

1. By forcibly preventing the offender from repeating his offence; as by death, mutilation, or perpetual imprisonment.

2. By reforming the habits of the offender, and thereby taking away the desire to offend.

3. By deterring the offender from repetition by the fear of fresh punishment.

4. By deterring others through example. And this last is clearly the chief practical end of all legal inflictions. The admission of other principles, in order to satisfy the idea of the existence of the state as a moral agent, need not prevent the legislator from keeping this steadily in view.

If Bentham's theory of punishment be defective in its main principles, it is so at all events only from being imperfect, not erroneous; as far as it goes, it is logical, consistent, and definite. And as he was nearly the first writer who introduced anything like clearness or arrangement into the popular notions on penal laws, so we are inclined to think that, on the whole, he has done more for society in this particular than in any other of the various subjects to which he applied his reforming genius. It must not be forgotten that Sir S. Romilly and Sir J. Mackintosh were the pupils who carried his speculation into practice.

Bentham divides punishments into corporeal and privative. The first of these are: 1. Simply afflictive, those which consist in the mere infliction of temporary pains, the lash, &c. 2. Complexly afflictive, in which pain is joined with permanent loss: as in the old punishments of mutilation and disfigurement. 3. Restrictive, under which he classes together imprisonment, or the total deprivation of liberty, and banishment, which deprives of a certain portion of liberty. 4. Active or laborious; such as the galleys, hard labour, &c. Transportation combines this character with the former. 5. Privative punishments, or those which deprive the criminal, 1. Of life. 2. Of reputation only; such, perhaps, as the amende in French law. 3. Of property: as by fine and confiscations. 4. Forfeiture of condition; which, more or less, accompanies infamous punishments in most countries: e.g. civil infamy, in France, is attended with various disabilities. These punishments comprehend all the simple forms in ordinary use; but he adds a few, which he terms anomalous, and only mentions them in order to hold them up to general reprobation. 1. What he calls *vicarious* punishments; as when the family of a suicide are punished by the forfeiture of his chattels. 2. Transitive; when the penalty passes to future generations; corruption of blood in the English law. 3. Collective; of which he gives, as an instance, the punishment of corporations for the acts of individual corporators; a more ordinary one is, the compelling the inhabitants of a hundred to make good the damages occasioned by a riot. 4. Fortuitous; where individuals wholly unconnected with the offender are implicated, as it were casually, in the consequences of his crime; of which he gives as an instance, the avoidance of mesne conveyances by some kinds of confiscation, and consequent loss of innocent purchasers; and the imposition of deodands, where no negligence is imputed. (Bentham, *Theory of Punishments and Rewards*; *Ed. Rev.* vol. xxii.; Lucas, *Système Pénal*; De Tocqueville, *Du Système Pénitentiaire aux États-Unis*; J. S. Mill, *On Liberty*, ch. iv.)

On the subject of capital punishment, opinions have of late years undergone considerable modification. The argument which based the infliction of such punishment on an alleged divine command, supposed to be contained in Genesis, has been tacitly, if not avowedly, abandoned, and the argument from expediency has been more prominently brought forward in its stead. The *Report of the Royal Commission on Capital Punishment*, 1866, recommends the substitution of private for public executions, and proposes to introduce a distinction between two varieties of crimes, now classed together as murder and capitally punishable. Of the commissioners, two were in favour of the immediate abolition of the death penalty. The gradual change in opinion on this subject is illustrated in Lord Russell's *Treatise on the English Government and Constitution*. In the first edition, published in 1825, Lord John Russell, while declaring that 'there cannot be many offences to which capital punishment ought to be attached,' asserted that 'all wilful acts tending directly to inflict death ought to be punished with death,' and added that, 'murder, stabbing, shooting at, burning of dwelling-houses or buildings contiguous to dwelling-houses, and setting fire to the clothes of a person, are crimes of this description.' In the introduction to the second edition, published in 1865, Lord Russell, while still he doubts not the right of a community to inflict such punishment, or the expediency of exercising that right in certain states of society, adds, 'When I turn from that abstract right and that abstract expediency to our own state of society, when I consider how difficult it is for any judge to separate the case which requires inflexible justice from that which admits the force of mitigatory circumstances, how invidious the task of the secretary of state in dispensing the mercy of the crown, how critical the comments made by the public, how soon the object of general horror becomes the theme of sympathy and pity, how narrow and how limited the example given by this condign and awful punishment, how brutal the scene of the execution, I come to the con-

clusion that nothing would be lost to justice, nothing lost in the preservation of innocent life, if the punishment of death were altogether abolished.'

Punneeria. An Indian genus of *Solanaceæ*, found in Scinde and Afghanistan. The berries of the only species, *P. coagulans*, a shrubby plant, growing from one to three feet high, are known to the natives as possessing the property of coagulating milk, in the same manner as rennet, for which they are substituted by the Beloochees and Afghans, who call them *punneer-bund*, i.e. cheesemaker.

Punt (Dutch pont, Fr. ponton). A small open pontoon, resembling a boat with a flat bottom and ordinarily with square ends. Though occasionally fitted for oars, the punt is in general propelled by poles acting on the bottom. It is useful for navigating shallow waters, as rivers, marshes, &c., or for any operation in which a steady base is desirable.

Pupa (Lat.). A genus of land snails, so called from the resemblance of the shell to the pupe, or chrysalis of an insect. Several species are British, as *Pupa umbilicata*, Drap.; *P. marginata*, Drap.; *P. edentula*, Drap.

Pupa (Lat. pupa). The name of the oviform nymphs of lepidopterous insects; also applied to metabolian insects generally, when in the second stage of their metamorphosis.

Pupil (Lat. pupilla). A term applied to the central opening of the eye, because it reflects the diminished image of the person who looks into it. It is the central aperture of the *iris*.

Pupil (Lat. pupillus). In Jurisprudence, properly, an infant or other under a *guardian*; popularly, a scholar under a teacher.

Pupipara (Lat. pupa, and pario, *I bring forth*). Those insects are said to be pupiparous which produce their young in the condition of a pupe or nymph; as the forest-fly, *Hippobosca equina*.

Pupivora (Lat. pupa, and voro, *I devour*). The name of a tribe of Hymenopterous insects, comprehending those of which the larvæ live parasitically in the interior of the larvæ and pupæ of other insects.

Purana (Sansc. *a poem*). The sacred books of India which contain the explanation of the Shaster. There are eighteen books of the Puranas; chiefly filled with legends of the inferior gods and the heroes of Hindustan. (*Mem. de l'Acad. des Inscr.* vol. xxxviii.) Much doubt is entertained as to the great antiquity of the Puranas. (Professor H. H. Wilson, translation of the *Vishnu Purana*, *Asiatic Journal*, Dec. 1840; Max Müller, *His. of Sansk. Lit.*)

Purbeck Beds. A compact shelly limestone or imperfect marble, alternating with clay and fossil limestones, resting on the Portland beds, and forming the uppermost group of the great series of the oolites in England. Among the beds are some which are called Dirt-beds; these seem to have been portions of an ancient vegetable soil. Others are marbles, used in churches and other buildings in some parts of England. Most of them are of fresh-water origin. The Purbeck beds are thin, but persistent, over a considerable space in the county of Dorsetshire; they are, however, very local, no exact representative appearing in the middle or north of England, and none on the Continent.

Above the dirt-beds of the Purbeck series are compact beds of oyster shells, known locally as the Cinder-bed, and others occasionally quarried for building-stone and slate. The well-known Purbeck marble, loaded with remains of *Paludina*, occurs in the upper parts of the series.

The lithological characters of the Purbeck beds, as well as their order of succession and the nature of their fossils, is shown in considerable detail in the published sections of the Geological Survey of Great Britain.

Purchase. In Law, generally the acquisition of lands or tenements by any other means than descent; as by devise, gift, or contract.

Purgatory (Lat. purgatorius, *cleansing*). A place appointed for the satisfaction of temporal punishments, which, according to the Roman Catholic church, are distinguished from the eternal, the latter only being remitted by the death of Christ. The doctrine of purgatory, which Augustine of Hippo mentions as a new opinion, was much discussed between the Greeks and Latins at the council of Ferrara, 1438. The present Roman Catholic belief is thus expressed in the creed of Pope Pius IV.: 'Constanter teneo purgatorium esse, animasque ibi detentas suffragio fidelium juvari.' To which it may be added, that the sins supposed to be punished in purgatory are of two kinds —mortal, but repented of; and venial. This article of the creed is derived from the canon of the council of Trent on the subject, sess. 25. The 'Romish doctrine' of purgatory is condemned by Art. 22 of the English church. The reader will find the general argument for purgatory well stated (among Protestants) by Hooker in his 3rd Sermon; the latter part, in which he replied to it, is lost. See also *Tracts for the Times*, No. 79.

Purification (Lat. purificatio, *a cleansing*). An observance enjoined on the Jews upon occasion of certain accidental deflements which are scrupulously recorded in the Levitical code. The purification was generally by water; and in the case of women, who were considered impure after childbirth for the space of forty days if delivered of a male, and eighty if of a female, the offering of a lamb or some other sacrifice was required. The purification of the Virgin Mary is a festival in the calendar, and is observed on February 2, being forty days after Christmas. This festival was established in the sixth century, and is variously termed in ecclesiastical antiquities by the names of Festum Candelarum, Candlemas, the Presentation. The processions of this day were instituted by Gregory the Great.

For an account of the ceremonies of purification among the Greeks and Romans, see Lustration.

Purim. The name of the solemn festival among the Jews in which they commemorate their deliverance from the wiles and stratagems of Haman, as recorded in the book of Esther. The observance of this festival has been religiously maintained by all the Hebrew race down to the present time. It is a movable feast.

Purism (Lat. purus, *pure*). Asceticism in taste; a preference for the emaciated and affected to the beautiful and natural. Overbeck may be considered as one of the most prominent of the Purists. [QUATTROCENTISMO; PRÆRAPHAELITE.]

Purist. A name sometimes applied to rigorous critics of purity in literary style.

Puritans. The name by which the dissenters from the church of England were generally known in the reign of Elizabeth and the first two Stuarts. The term was applied to them from the fact that they professed to follow the Word of God alone, purified from all human inventions and superstitions, of which they believed the English church to retain a considerable share, notwithstanding its alleged reformation. According to Fuller, the use of the name commenced about 1564. (Neale's *History of the Puritans.*) [DISSENTERS.]

Purlin. In Architecture, a piece of timber lying on the principal rafters of a roof, for the purpose of dividing the length of the bearing of the common rafters.

Purple (Gr. πορφύρα, Lat. purpura). In Painting, a colour produced by the mixture of red and blue, and thence partaking of the hue of each. Among the ancients, purple was always the distinguishing badge of power and distinction; and, of all the various kinds in use, the Tyrian dye is the most celebrated. This colour was produced from an animal juice found in a shell-fish called *murex*, or *conchylium*, the quality of which, however, varied with the different coasts on which it was caught. [MUREX.]

Purple of Cassius. A compound of the oxides of tin and gold, obtained by adding a mixture of protochloride and perchloride of tin to a solution of chloride of gold. It is used as a purple colour for porcelain painting, and also for staining glass, to which it imparts a fine ruby red.

Purple Copper-ore. A mineral of the composition $3\,Cu_2\,S+Fe_2\,S_3$ containing from 55 to 70 per cent. of copper. [ERUBESCITE.]

Purpura (Lat. *purple*). An eruption of small purple specks and patches, caused by extravasation of blood under the cuticle; it is attended by constitutional debility, and sometimes by fever. Aperient medicines, and occasional purgatives, carried to a greater or less extent, followed by mild tonics, and in some cases by wine, bark, and acids, are the principal remedies; but, in the treatment, much will depend upon the concomitant symptoms.

PURPURA. In Zoology, a generic name of the univalve Gastropod which secretes the purple fluid forming the base of the Tyrian dye. [MUREX.]

Purpure. *Purple.* In Heraldry, one of the colours or tinctures used in blazonry. It is equivalent to amethyst among precious stones, Mercury among planets. In engraving, it is represented by diagonal lines from the sinister to the dexter side of the escutcheon.

Purpuric Acid. A substance resulting from the action of nitric acid upon uric acid; it forms deep red or *purple* compounds with most bases. [MUREXIDE.]

Purpurifers (Lat. purpura, *purple*; fero, *I bear*). The name of a family of Gastropodous Molluscs, including those species which secrete the purple substance forming the celebrated dye of the ancients.

Purpurin. One of the colouring matters of madder; closely allied to alizarin.

Purree or **Indian Yellow.** A yellow colouring matter imported from India and China. Its origin has not been accurately ascertained, but it is supposed to be of animal origin, and to consist of a peculiar acid (*purreic* or *euxanthic acid*) combined with magnesia. [EUXANTHINE.]

Purse. A Turkish money of account containing 500 piastres, and worth on the average (for Turkish money is very debased) about 4*l.* 13*s.* 9*d.* sterling.

Purser (from *purse*, Fr. bourse, Ital. borsa, Gr. βύρσα). Formerly an officer in the British navy, whose chief duty consisted in keeping the accounts of the ship to which he belonged; but he also acted as purveyor. The title of this officer has been since 1844 PAYMASTER.

Pursuit, Curve of. The curve described by a point which pursues, with uniform velocity, another point which describes with a different, but still uniform, velocity a given right line not passing through the first point. The curve was first discussed by Bouguer in the *Mémoires de l'Académie*, 1732. It again came under discussion in consequence of a problem, respecting a dog following its master, which was proposed in the *Correspondance de l'École Polytechnique*, t. ii., and which was solved by St. Laurent in Gergonne's *Annales*, vol. xiii. The arcs of the curve are obviously proportional to the intercepts, on a fixed line, between the tangents at their extremities. Taking the fixed line as ordinate axis, the intercept upon it made by the tangent at (xy) will be $y-x\dfrac{dy}{dx}=y-px$. The increment of this, which is $-x\,dp$, being proportional to the increment of the arc, which is $ds=dx\sqrt{1+p^2}$, we have at once, for the differential equation of the second order,

$$x\,dp+\lambda\,dx\sqrt{1+p^2}=0,$$

where λ is the relative velocity of the two points. By integration we arrive at the equation of the curve, which contains two arbitrary constants a and b, and may be written in the form

$$2\,(y-b)=\frac{a}{\lambda+1}\,x^{\lambda+1}+\frac{a^{-1}}{\lambda-1}\,x^{-\lambda+1}.$$

The curve, therefore, is always algebraic ex-

cept when $\lambda = 1$, when a logarithmic term will enter into its equation.

Pursuivants. In Heraldry, a kind of probationers in the Heralds' College of England, not admitted to the full privileges of the college, but advanced by succession into its higher offices. They are styled *Portcullis*, *Rouge Dragon*, *Blue Mantle*, and *Rouge Croix*.

Purûravas. [URVASÎ.]

Purveyance (Fr. pourvoir, Lat. providere, *to provide*). Among the privileges possessed by the English monarchs down to the time of the Restoration, and the subsequent abolition of feudal incidents, was that which, known under the name of *purveyance*, entitled the officers of the household to take corn and cattle for the use of the king, and to employ beasts of burden for the carriage of the king's effects. As the monarch, like other great landowners or feudal lords, generally travelled from one manor or castle to another, accompanied by his retinue, and resided on the spot till the store was consumed, the infliction of purveyance was very general; and as the privilege, belonging originally only to the king and his family, was frequently usurped by his household, the burden was very severe. Moreover, as the payments were made in tallies on the exchequer, the prospect of such remuneration as the crown gave was very remote; and as the king bought in a larger measure than that fixed by the standard, the loss was large, as well as capricious in its incidence. Hence the statute book is full of enactments, limiting the number of persons who should possess the privilege, defining the measure by which the corn should be purchased, prescribing the occasions and times for impressing beasts of burden, and assuring the payment of the debts incurred. As, however, these statutes are constantly repeated, we may conclude that they were constantly broken, and we know from the rolls of Parliament that the grievance was felt to be intolerable. In order to evade these exactions bribes were freely given, and to large amounts, to the king's officers, either with a view of getting rid of the purveyance altogether, or with that of making the transaction as light as possible. The system, as far as regards purchases and impressments of cattle, was got rid of by stat. 12 Ch. II.

The only relic of purveyance which remains to the present day, is the right possessed by the crown, and exercised through the War Office, of billeting soldiers upon innkeepers, the ratio at which the soldier is to be lodged and boarded being fixed by the military authorities. In practice this exaction does not fall upon the metropolis or on such towns as have permanent barracks, and is perhaps not over-onerous in other places since the facilities of transit have been so considerably increased by railway communications. But in theory the system belongs to a bygone age, is partial in its incidence, and unjust in principle. It is possible that, while the billeting of soldiers on small public-houses may be no inconvenience to the owners, and even indirectly a source of profit, it may fall with undue severity on such inns as are constructed for the accommodation of the wealthier classes. Of course it is impossible for the innkeeper to house his involuntary guests, and he has to pay for their lodging elsewhere. This payment forms a tax upon his occupation, heavy because it affects some of the traders and not others, and because, if shifted at all, it is put upon those who make use of the inn, in enhanced rates for food and lodging.

Pus (Lat.). A bland yellowish fluid, somewhat like cream, found in abscesses, and formed upon the surfaces of what are termed healthy sores; it is heavier than water, and when viewed under the microscope appears composed of translucent globules floating in a colourless serum. The globules contain fatty matter and cholesterin. An albuminoid substance has also been found in pus, called *pyin*, soluble in water, but precipitated by acetic acid and by a solution of alum. Boedecker has announced the presence of leucin and of a peculiar crystallisable acid in pus, which he calls *chloridic* acid, and Forbes has obtained a blue compound (*pyocyanin*) from certain purulent secretions which are occasionally met with, and which leave a blue stain on linen.

Puschkinite. A green, yellow, or red variety of Epidote from Siberia.

Putamen (Lat.). In Botany, the inner coat, or shell, or stone of a fruit; commonly called the *endocarpium*.

Putchuk. One of the Eastern names applied to the roots of the Costus, *Aplotaxus Lappa*.

Putlog. In Architecture, short pieces of timber used in scaffolds, for supporting the scaffold boards. They are placed at right angles to the wall, one end of them resting on the ledges of the scaffold, and the other on holes left for them in the wall. In many of the ancient Roman buildings, as in the Pont du Gard, the holes thus left are treated as parts of the ornamentation of the building, under the name of *columbaria*, according to Vitruvius, from the supposed resemblance of the holes so left to the holes in a dove cote.

Putorius (Lat. putor, *a stench*). A genus of carnivorous mammalia, distinguished from the Martens, to which they are most nearly allied, by their shorter muzzle, the suppression of one premolar above and below, and the absence of an internal tubercle to the lower *carnassial* tooth. The polecat (*P. fœtidus*), of which the ferret is an albine variety, the weasel (*P. vulgaris*), and the stoat or ermine (*P. herminea*), form the English representatives of the genus.

Putrefaction (Lat. putrefacio, *I make rotten*). The spontaneous decomposition of animal and vegetable substances, attended by the evolution of fetid gases. The putrefaction (or putrefactive fermentation) of animal substances is usually attended by more fœtid and noxious exhalations than those arising from vegetable products. This appears principally referable to the more abundant presence of

nitrogen and of sulphur in the former; and hence the vegetables which abound in these principles (such as most, if not all, of the cruciferous plants) exhale similar effluvia: hence, also, such animal products as are destitute of nitrogen are either unsusceptible of what is commonly called putrefaction, or suffer it slowly and imperfectly. The formation of ammonia, or of ammoniacal compounds, is a characteristic of most cases of animal putrefaction; while other combinations of hydrogen are also formed, especially carburetted hydrogen, together with complicated and often deleterious vapours or gases, in which sulphuretted hydrogen is discerned. These putrefactive effluvia are for the most part easily decomposed, and resolved into new and comparatively innocuous compounds, by the agency of chlorine; hence the importance of that body as a powerful and rapidly acting disinfectant.

The rapidity of putrefaction, and the nature of its products, are to a great extent influenced by temperature, moisture, and access of air; they do not ensue below the freezing point, nor in dry substances, nor under the entire exclusion of oxygen; and hence various means suggest themselves of retarding or preventing putrefaction, as well as of modifying its results: a temperature between 60° and 80°, a due degree of humidity, and free access of air, are the circumstances under which it proceeds most rapidly. The most effective antiputrefactives or antiseptics are substances which either absorb or remove a portion of the water or moisture, and enter into new combinations with the organic matter; hence the great efficacy of certain salts, sugar, alcohol, and several other applications, among which, perhaps, the most remarkable are carbolic acid and some volatile oils, such especially as kreasote and other empyreumatic products obtained by the destructive distillation of wood, pyroligneous acid, and pyroligneous spirit: the latter is eminently useful in the preservation of dead bodies for the purposes of dissection, and, when properly and sufficiently injected into the vessels, and externally applied, indefinitely suspends the ordinary steps of the putrefactive process.

The astringent or tanning principle of vegetables is also a powerful preserver of most organic tissues; it enters into chemical combination with the albuminous and gelatinous membranes and fibres; and the resulting compound, of which leather furnishes a characteristic example, is comparatively little prone to change.

Among saline substances, the antiputrefactive powers of salt are commonly known. When a piece of flesh is salted, brine runs from it, in consequence of the energy with which the salt abstracts the water of the muscular fibre; the flesh becomes indurated, and its susceptibility to putrefactive changes greatly diminished; it becomes at the same time less easy of digestion as an article of food. Corrosive sublimate is a more powerful preservative than common salt; and it appears to act not by the mere abstraction of water, but by rendering impossible the developement of animalcules, to which, as Pasteur has lately demonstrated, all putrefactive processes are essentially due. Sulphate of copper and several other metallic salts are similarly efficacious; and the most putrescible substances, as for instance the brain, after having been steeped in such solutions and dried, will remain without further change for an indefinite period. The poisonous nature of these and many other metallic salts prevents their employment in the preservation of articles of food.

It is probable that the ancient Egyptians employed several of the above-mentioned antiputrefactive and preservative substances in the preparation of their mummies, which have remained for so many hundred years without signs of decay or decomposition. Yet in these and similar cases, when by the careful application of various solvents the preservative substances are removed, the flesh resumes its susceptibility of putrefaction.

The inhabitants of northern climates avail themselves of freezing to prevent the putrefaction of their food, and the supplies of game and other articles in the Russian markets are retained in a frozen state. Our fishmongers resort to the same expedient for the preservation of their unsold fish, which is daily removed to the ice-house after having been exhibited in their shops. Salmon is packed in ice for the purpose of transport and preservation. [PRESERVATION OF MEAT.]

It is curious to remark the wonderful influence of vitality in opposing those chemical changes which constitute putrefaction, and in retaining that arrangement of the organic elements which is requisite for the functions of life. When a part of the body dies, the phenomena of gangrene or mortification, i.e. of local putrefaction, ensue; and the putrefactive changes are the more energetic in consequence of the proximity of the dead part to the living.

All organic tissues may be indefinitely preserved by cautious desiccation; and it is in consequence of the comparative absence of water that the animal part of bone resists putrefaction. Dried bones may thus be stored up for ages; and when it is required to extract their nutritive parts, these are found but slightly impaired.

Putty (Fr. potée). In Architecture, a very fine cement used by plasterers, made of lime only. It differs from fine stuff in the manner of preparing it, and in its being used without hair. Also a composition used by glaziers for the purpose of fixing sheets of glass in the wood frames. It consists of whiting and linseed oil.

Pycnite (Gr. πυκνός, *dense*). Schorlous Topaz. A massive variety of Topaz, having a parallel columnar structure and oblique transverse divisions, along which it may be easily broken. It is translucent, and of a dull yellowish or reddish-white colour. It is a silicate of alumina, with one-seventh of the oxygen

replaced by fluorine. The chief localities where it is found, are at Altenberg, in Saxony; and Schlackenwald and Zinnwald, in Bohemia.

Pycnodontes (Gr. πυκνός, and ὀδούς, *tooth*). A family of fossil lepidoganoid fishes, in which the vomer, as in *Anarrhichas*, opposes its pavement of teeth to that of the two closely approximated premandibular or dentary elements of the under jaw. They were mostly deep-bodied fishes, symmetrically compressed from side to side. They were notochordal; a few of the earlier forms were heterocercal, but the majority of the family were homocercal. The family is found from the carboniferous to the earlier tertiary periods.

Pycnostyle (Gr. πυκνόστυλος). In Architecture, an arrangement of columns in which the intercolumniations are equal to one diameter and a half of the columns.

Pycnotrop. A kind of Serpentine.

Pygmy (Gr. πυγμαῖος, *dwarfish*; from πυγμή, *a cubit*). By ancient authors on natural history this name was applied to a fabulous race of dwarfish human beings; it is now restricted to a species of ape, the *Troglodytes niger* of Geoffroy St. Hilaire, or the chimpanzee. (Tyson's *Anatomy of a Pygmie*, with an Essay concerning the Pygmies of the Ancients, fol. 1699.) Homer (*Il.* bk. iii.) described a nation of pygmies dwelling somewhere near the shores of the Ocean stream, and maintaining perpetual wars with the cranes. Ctesias, the Greek historian, as quoted by Photius, represented a nation of them as inhabiting India, and attending its king on his military expeditions. Others believed them to inhabit the Indian islands; and Aristotle places them in Ethiopia, Pliny in Transgangetic India. These numerous fables appear to originate partly, as Strabo long ago observed, in the stunted growth of particular races, under the sufferings of a severe climate or great privations; thus the Esquimaux or Laplanders furnished the ancient Northmen with their legendary *Dwergar*, or nations of malicious dwarfs. Some of the low-caste races which inhabit the forests of interior Hindustan are feeble and puny enough to have given origin to the account of Ctesias; while the pygmies of the Malay Archipelago and the interior of Africa were probably apes.

Pyin. [Pus.]

Pylagoras (Gr. πυλαγόρας, so called from the assembly of the Amphictyons at Pylæ or Thermopylæ). The title of one of the two deputies from each confederate at the Amphictyonic Council. His functions comprised the diplomatic and deliberative duties of the mission: while the care of the sacred rites fell on his colleague, the Hieromnemon (ἱερομνήμων).

Pylorideans (a word coined from Gr. πυλωρός, *a gatekeeper*, and εἶδος, *likeness*). The name of a tribe of Lamellibranchiate Bivalves, comprehending those which have a shell open at both extremities.

Pylorus (Gr. πυλωρός). The aperture of the stomach into the duodenum; it guards, as it were, the entrance into the intestinal canal.

Pyocyanin. [Pus.]

Pyrallolite (Gr. πῦρ, *fire*; ἄλλος, *other*; and λίθος, *stone*). An altered form of Augite in which magnesia takes the place of lime. It occurs, of a greenish-white to a yellowish-grey colour, at Pargas in Finland, generally massive. The name has reference to the change of colour which takes place before the blowpipe.

Pyramid (Gr. πυραμίς). In Geometry, a solid contained by a plane polygonal base and other planes meeting in a point. This point is called the vertex of the pyramid; and the planes which meet in the vertex are called the sides or faces. These are necessarily all triangular.

The principal properties of pyramids are the following: 1. Every pyramid is equivalent to one-third of a prism having the same base and altitude. Hence, 2. All pyramids having equivalent bases and equal altitudes are equivalent. 3. The solid content of a pyramid is measured by the product of the area of the base into one-third of the altitude. 4. If a pyramid is cut by a plane parallel to its base, the frustum (or part comprehended between the base and the section) is equal to the sum of three pyramids having for their common altitude that of the frustum, and of which the bases are respectively the lower base of the frustum, the upper base of the frustum, and a mean proportional between them. (Legendre's *Geometry*, and Notes.)

Pyramids are denominated from the figures of their bases, being *triangular*, *quadrangular*, *pentagonal*, &c., according as the base is a triangle, a quadrangle, a pentagon, &c.

Pyramids of Egypt. Celebrated monuments of massive masonry, which, from a square base, rise by regular gradations till they terminate in a point, but so that the width of the base always exceeds the perpendicular height. The pyramids commence immediately south of Cairo, but on the opposite bank of the Nile, and extend in an uninterrupted range for many miles in a southerly direction, parallel with the banks of the river.

The three largest are situated in the vicinity of Ghizeh, not far from Cairo; and of these the loftiest is called the pyramid of Cheops, from the prince by whom it is supposed to have been erected. The sides of its base, which are in a line with the four cardinal points, measure at the foundation 763·4 feet; so that it occupies a space of more than 13 acres. Its perpendicular height is 480 feet, being, consequently, 43 feet higher than St. Peter's at Rome, and 136 feet higher than St. Paul's. Supposing this pyramid to be entirely solid, its contents would exceed three millions of cubic yards, and the mass of stone contained in it would be six times as great as that contained in the Plymouth breakwater! This huge fabric consists of successive tiers of vast blocks of calcareous stone, rising above each other in the form of steps. The thickness of the stones, which is identical with the height of the steps, decreases as the altitude of the pyramid increases, the greatest

height being 4·628 ft. and the least 1·686 ft. The mean breadth of the steps is about 1 ft. 9 in. The best authorities agree in estimating the number of steps or tiers of stone at 203. According to the information communicated to Herodotus by the priests, 100,000 men were employed for twenty years in the construction of this prodigious edifice; and ten years were employed in constructing a causeway by which to convey the stones to the place, and in their conveyance. (Lib. ii. § 124.)

The other pyramids, although of inferior dimensions, are mostly all of vast magnitude: they are not all of stone, some of them being of brick.

Many learned dissertations have been written to account for the original use and object of these imperishable structures. But the difficulty of the subject is such, that hitherto no satisfactory conclusion has been arrived at. Even in the remotest antiquity their origin was matter of doubt, and nothing certain was known with respect to them or their founders. (Plin. *Hist. Nat.* lib. xxxvi. § 12; Diodorus, i. 64.) Some have supposed that they were intimately connected with the religion of the ancient Egyptians; others have thought that they were at once a species of tombs and temples; while others again have maintained that they were designed to serve as gnomons, an opinion countenanced by the fact of their being placed in the direction of the four cardinal points. (Shaw's *Travels*, p. 170 &c. 4to. edit.; Greaves's 'Pyramidographia,' *Works*, vol. i.; Bunsen, *Egypt's Place in Universal History*; Piazzi Smyth, *Our Inheritance in the Great Pyramid*.)

The question of the date of the great Egyptian buildings has been examined by Sir G. C. Lewis in his treatise on the *Astronomy of the Ancients*, p. 440, &c., and his conclusion is that there is not sufficient historical ground for placing any of them at a date anterior to that of the building of the temple of Solomon, 1012 B.C. (*Edin. Rev.* Jan. 1857, p. 125; July 1862, p. 100.) This assertion has been received by some with 'profound astonishment.' It is, however, obvious that Sir G. C. Lewis does not fix their date, all that he asserts being that we have no *historical* warrant for ascribing them to an earlier age. According to Herodotus, the pyramid kings reigned from about 913 to 813 B. C. 'Astronomers, who tell us that 3,970 years ago the star γ Draconis fulfilled the office of a pole star, accept that date for the pyramids (B. C. 2123 for the great pyramid), because they have openings on the north side 'leading to straight passages, which descend at an inclination varying from 26° to 27°, the direction of these passages being in all cases parallel to the meridian: now if we suppose a person to be stationed at the bottom of any one of these passages, and to look up it as he would through the tube of a telescope, his eye will be directed to a point in the meridian 26° or 27° above the plane of the horizon; and this is precisely the altitude at which the star γ Draconis must have passed the lower meridian at the place in question 3,970 years before the present time.' (Chambers, *Handbook of Astronomy*, p. 270.) It might have been thought that the astronomical argument would have been welcomed by Baron Bunsen; but it did not fit in with his scheme, and hence apparently he has thrown the pyramids still further back by more than a thousand years.

The etymology of the word *pyramid* is involved in as great obscurity as the object of the structures themselves. Almost all the derivations that have been assigned to the term proceeded on the supposition that it is of Greek origin, than which nothing can be more erroneous. De Sacy regards the ις in πυραμίς as a Greek termination; the first syllable πυ he holds to be the Greek version of the Egyptian article *pi* (and so written by the Greeks from their wish to derive the word from πῦρ, *fire*); and he refers the syllable ραμ to the root *ram*, which, in the Egyptian language, signified *separating* or *setting apart from common use*: consequently, the word *pyramid* will denote a *sacred place or edifice* set apart for some religious purpose. (De Sacy, *Observations sur l'Origine du Nom donné par les Grecs et les Arabes aux Pyramides d'Ægypte*; M'Culloch's *Geog. Dict.* art. 'Egypt.')

Pyramids of Mexico. Some of the Mexican pyramids have a larger base than even the pyramids of Egypt. The pyramid of Cholula has a truncated form, and faces with its four sides the cardinal points, being divided into the same number of terraces. It is possible that the interior of this pyramid may be a natural hill, but more probably it is an artificial composition of stone and earth, deeply encrusted in every part with alternate strata of brick and clay. The perpendicular height of this pyramid is 127 feet, the base being 1,423 feet, or twice as long as that of the pyramid of Cheops. On the summit stood the temple of Quetzalcoatl, the god of the air. The larger of the two great pyramids of Teotihuacan, dedicated, the one to Tonatiuh, the sun, the other to Meztli, the moon, is 682 feet in length at the base. Around these are many smaller pyramids, rarely exceeding 30 feet in height, and said to have been dedicated to the stars. They served also as sepulchres for the chiefs of the nation. (Prescott, *Conquest of Mexico*, book iii. ch. i. and book v. ch. iv.)

Pyramidal Numbers. In Arithmetic, the successive sums of polygonal numbers, the latter being obtained by the successive summation of numbers in arithmetical progression. Pyramidal numbers are FIGURATE NUMBERS of the third order.

Pyrantimonite. Red Antimony-ore. [KERMESITE.]

Pyrargillite (Gr. πῦρ, *fire*, and ἄργιλλος, *clay*). A hydrated silicate of alumina, protoxide of iron, magnesia, soda and potash, found in granite at Helsingfors in Finland. It occurs massive and in prismatic forms with an indistinct cleavage, and in colour is partly black

and shining or partly bluish and lustreless; also liver-brown or dull red. According to Bischof, it is an altered form of Iolite.

Pyrargyrite (Gr. πῦρ, and ἄργυρος, *silver*). Dark-red ruby Silver-ore. A sulphantimoniate of sulphide of silver ($Ag\,S + Sb\,S_3$), containing about 60 per cent. of silver. It crystallises in complex modifications of the hexagonal system, and is also found massive. Colour deep blood red when seen by transmitted, and dark grey or black with an adamantine lustre, by reflected light. It is one of the most important of silver ores, and occurs in quantity in the Harz, Saxony, Bohemia, Hungary, and Mexico, also in Washoe Nevada, and the western states of South America. The light-red ruby ore is similar in form, and differs in composition only in the substitution of arsenic for antimony in the second term. [PROUSTITE.]

Pyrenees. This mountain-chain, rising like a wall separating Spain from France, is chiefly interesting in physical geography as connected with the table-land of Spain which extends between the Pyrenees and the Sierra Nevada, interrupted at intervals by several ranges of hills rising only to a moderate elevation. The Pyrenean chain is quite separated from the Alps, and has little resemblance to it either in its style of mountain scenery or in the forms of the valleys. The average height is considerable, the chain remarkably uniform, the general effect being that of a serrated ridge. The breadth of the range is comparatively small, nowhere exceeding sixty miles, and generally much less. The length is a little less than 600 miles from the gulf of Lyons to the Atlantic. The culminating point of the chain is rather more than 11,000 feet above the sea, and the sides are much steeper towards France than Spain. There are few passes, none of them being either good or practicable at all seasons, except two, one near Perpignan on the east, and one near Bayonne on the west.

Pyreneite. A black or greyish-black variety of Iron-lime Garnet, occurring in small but very perfect rhombic dodecahedrons, in the limestone of the Pic d'Ereslids, in the Pyrenees.

Pyrethrum (Gr. πύρεθρον, *feverfew*). One of the genera of *Compositæ* which have a medicinal reputation. The popular species is *P. Parthenium*, otherwise called Feverfew, from its being a domestic remedy in slight fevers. It possesses bitter tonic properties. Some forms of the plant in which the flower-heads consist wholly of ligulate florets, and others in which the quilled yellow disc florets of the wild plant are exchanged for large white quilled florets, both being of an ornamental character, are met with in flower gardens, notwithstanding their strong and not very agreeable odour.

Pyretology (Gr. πυρετός, *fever*, and λόγος). The doctrine of fevers.

Pyrexiæ (Gr. πύρεξις, *feverishness*). Febrile diseases. The first class in Cullen's nosology.

Pyrgom (Gr. πύργωμα, *a fortress*). A dingy green variety of Sahlite, found in the Fassa valley, in the Tyrol.

Pyridine. An oily organic base found amongst the products of the distillation of bone.

Pyrites (Gr. πυρίτης, sc. λίθος). This term was originally applied to the harder varieties of bisulphide of iron which strike fire with steel. The German equivalent *kies* probably expresses the same idea as *kiesel*, flint, for in the earliest forms of fire-arms the charge was ignited by a piece of pyrites striking against the steel covering the pan, the use of flints for the same purpose being a later improvement. At the present time, when used alone, pyrites is usually understood as expressing Iron Pyrites.

The various terms compounded of Pyrites, expressing sulphides and arsenides of different compositions, are translations of the corresponding compounds of *kies*. Such are Copper Pyrites, Arsenical Pyrites, Nickel Pyrites, Cobalt Pyrites, and Magnetic Pyrites. Taken as the name of a group in this way, the term Pyrites forms one of the three divisions of minerals, used by the old German miners, namely, *kies* or Pyrites (hard ores?), *glance* or glassy ores, and *blende* or brilliant ores. According to Koch, *marcasites*, another old term for Pyrites, is of Arabic origin, and also signifies fire-stone. The common term for Pyrites used in Cornwall is *mundic*.

Pyro-Acids. The prefix *pyro* is usually applied to the products which are obtained by subjecting certain organic acids to heat. The acids are thus altered in composition, and give rise to distinct classes of salts. Thus we have the pyrogallic, pyrocitric, pyrotartaric acids, &c.

Pyroacetic Spirit. A liquid formed during the destructive distillation of acetate of lead. [ACETONE.]

Pyrochlore (Gr. πῦρ, *fire*, and χλωρός, *pale green*). A compound of columbic and titanic acid with lanthanum, lime, potash, soda, zirconia, yttria, &c.; found in Norway, and near Miask in Siberia. The name refers to the change in colour, before the blowpipe, of the glass which the mineral forms with microcosmic salt.

Pyrodmalite (Gr. πῦρ, *fire*; ὀδμή, *odour*; and λίθος, *stone*). A name given to Pyrosmalite, from the odour which it gives off when heated.

Pyrolaceæ (Pyrola, one of the genera). A small natural order of the Erical alliance of hypogynous Exogens, distinguished by its semi-monopetalous flowers, its free perfect stamens, its loose-skinned seeds, and its baseless embryo. *Chimaphila umbellata*, a North American species of the order, is powerfully diuretic. Some *Pyrolas* are found wild in England.

Pyroligneous Acid (Gr. πῦρ, and Lat. lignum, *wood*). This term is generally applied to the *acid liquor* which passes over along with other products when wood is subjected to destructive distillation. This acid liquor is an impure vinegar, from which acetic acid is obtained as follows: The pyroligneous acid, freed from tar, is saturated with chalk or powdered slaked lime, filtered, and evaporated, by which an impure acetate of lime is obtained; this

is gently heated, so as to destroy part of its empyreumatic matter without decomposing the acetic acid; it is then mixed with sulphate of soda, which yields, by double decomposition, sulphate of lime and acetate of soda; the acetate of soda is filtered off the sulphate of lime, evaporated, heated cautiously in a reverberatory furnace, and redissolved and crystallised. In this way a pure crystallised acetate of soda is by proper management obtained, which is mixed in a retort or still with an equivalent proportion of sulphuric acid, a gentle heat being applied. The strong acetic acid then distils over, and sulphate of soda remains behind. This acetic acid is in a high state of concentration; it is lowered by the addition of water, and if intended for the table or for domestic use, as a substitute for other forms of vinegar, it is usually coloured with a little burnt sugar. The charcoal which is the residue of this distillation of wood is of an excellent quality. The charcoal employed in the manufacture of gunpowder is thus prepared. This manufacture of vinegar is now carried on upon a very large scale, and the greater part of the vinegar used for domestic purposes and in the arts, in many of which it is largely consumed, is derived from this source. The hard woods, such as beech, oak, birch, and ash, are most productive of acetic acid, some of them yielding as much as four per cent. [VINEGAR.]

Pyroligneous Spirit. [PYROXYLIC SPIRIT.]

Pyrolusite (Gr. πῦρ, *fire*, and λύσις, *a loosening*). A mineralogical term applied to the common black ore of manganese, in consequence of the ease with which it is resolved by heat into oxygen and a suboxide.

It is a binoxide of manganese, composed of 63·64 per cent. of manganese and 36·36 oxygen. It sometimes occurs crystallised, but generally in botryoidal and reniform masses, with a radiating structure, or in granular masses. The colour is often bluish, but more frequently steel-grey, inclining to iron-black, with a metallic lustre. It is so soft as to soil the fingers when handled; a test which serves to distinguish this mineral from Psilomelane, with which it is frequently associated. It is found in Cornwall and Warwickshire, in Saxony, Bohemia, France, Brazil, &c.

Pyrolusite is the most valuable of the ores of manganese, from the large amount of oxygen which is contained in it, and renders it of great value in the preparation of chloride of lime, and in bleaching. It is also employed in the manufacture of glass for discharging the brown and green tints, and other colouring matters; in enamel and glass painting, and in colouring pottery. (Bristow's *Mineralogy*.)

Pyromancy (Gr. πυρομαντεία). Among the classical ancients, a species of divination by means of the fire of the sacrifice; in which, if the flames immediately took hold of and consumed the victims, or if they were bright and pure, or if the sparks rose upward in a pyramidal form, success was said to be indicated. If the contrary took place, misfortunes were said to be presaged. (Soph. *Antig.* 1005, &c.)

Pyromelite (Gr. πῦρ, and μήλινος, *quince-yellow*, from its becoming of that colour when first heated before the blowpipe). A hydrated sulphate of nickel, occurring in interlacing capillary crystals, but chiefly as a greenish efflorescence, at Wallace Mine, Lake Huron.

Pyrometer (Gr. πῦρ, *fire*, and μέτρον, *measure*). An instrument for measuring higher temperatures than can be determined by an ordinary thermometer. Various contrivances have been employed for this purpose. Muschenbroek, who gave the name *pyrometer* to this instrument in 1730, adopted the following method: A prismatic rod, about six inches long, of the metal under trial, is attached at one extremity to an immovable obstacle, and heated by lamps, the other end being necessarily pushed forward; this being fastened to a rack playing into a pinion, communicates a revolving motion to an axle to which a train of wheel-work is attached; and thus the minutest expansion of the heated bar is rendered sensible, and measured by an index on a dial. This method is liable to several objections, and the absolute temperature communicated to the bar by the lamps is entirely unknown. Desaguiliers, and afterwards Ellicott, made several improvements in the construction of the instrument, tending to give it a more equable motion and to increase its delicacy. Graham substituted a micrometer screw for the wheels and levers that had formerly been employed; and on this principle Smeaton contrived a far more accurate instrument with which the $\frac{1}{23\,000}$th of an inch of expansion was determinable. With this pyrometer Smeaton ascertained the expansion of various solids between the freezing and boiling points of water, and his results agree remarkably well with recent observations.

An ingenious mode of indicating the expansion of a metal bar by heat was invented by Ferguson, originally for lecture illustration, for which purpose it is well suited. By means of two levers of the second order the powerful motion of the expanding bar was converted into a considerable deviation of a long but light index, moving over a graduated arc. Though thus simple in its construction, this instrument is said to be delicate enough to show variations of its index merely from the heating of its metal bars by slight friction. Subsequently, Ferguson rendered his instrument so sensitive that it readily showed the expansion of a bar to the $\frac{1}{75000}$ of an inch. A more accurate method of measuring the dilatation of a bar by heat was devised by Ramsden, for the purpose of determining with the greatest precision the expansibility of the rods employed by General Roy in his trigonometrical survey. The expansion of the tested bar, which was caused to pass through changes of temperature, was compared with a standard bar kept at a constant temperature. This was done by direct observation through two microscopes provided with cross wires; the amount of this expansion

was ascertained by the movement which it was necessary to give to a micrometer screw in order to bring the expanded bar back to its initial position.

The instruments thus far described, though called pyrometers, have little claim to this term, for practically they are incapable of measuring very elevated temperatures, and even if they could do so their indications are unconnected with the ordinary thermometric scale. Wedgwood, by means of the pyrometer which bears his name, was the first to accomplish this object with any degree of success. He had found by repeated trials that fine porcelain clay contracted uniformly with the degree of heat applied to it, and on cooling remained thus contracted. Accordingly, by measuring the dimensions of a cylindrical piece of this substance, which was done with great accuracy by observing the depth to which it sank between two scales of metal inclined to each other under a small angle, and subjecting it to the heat of a furnace, then applying the scale again to it when cold, an indication of the degree of heat to which it has been subjected was given by the amount of its contraction. Wedgwood divided his scale into 240°; and, in order to compare it with that of Fahrenheit's thermometer, made use of a piece of silver fitted to the same mould as the pyrometric pieces of clay. Having determined the expansion of the silver between 50° and 212° of Fahrenheit's scale, he subjected the silver and clay to the same heat; and, by a comparison of the expansion of the one with the contraction of the other, he estimated that each degree of his scale was equal to 130° of Fahrenheit's. He also estimated that the zero of his scale corresponded with 1077·5° of Fahrenheit's; and from these data comparative tables of the two scales were formed. Clay, however, is a heterogeneous mixture, varying in its composition, and even different portions of the same clay might possess different contractile powers; the cylinders could not therefore be always alike, and thus their indications were not always the same. This uncertainty, and the erroneous conclusions to which Wedgwood was led by his pyrometer, caused it to be abandoned soon after its invention in 1782, and it has long since become obsolete. But Wedgwood's greatest error lay in the conversion of the scale of his pyrometer into degrees of Fahrenheit's thermometer. It was subsequently shown by Guyton de Morveau, and since confirmed, that Wedgwood assigned far too high a temperature for the degrees of his scale. The cause of this error was in the comparison of the contraction of clay with the expansion of silver, the connecting link between the Wedgwood and Fahrenheit degrees. Guyton, by means of his pyrometer, next to be described, estimated that each degree of Wedgwood, instead of being 130° Fahr., ought not to have been more than 62·5° Fahr., while the commencement of his scale should have been 517° Fahr. instead of 1077°.

Guyton de Morveau, in 1804, invented a platinum pyrometer, which, though a great improvement on Wedgwood's, yet, as subsequently pointed out by Daniell, was rendered liable to error by the softening and consequent flexibility of the platinum at high temperatures. This instrument is very similar to one constructed by Brongniart for determining the temperature of the porcelain furnaces at Sèvres; Brongniart using, however, a bar of silver instead of platinum. Guyton de Morveau's pyrometer consisted of a solid plate of highly baked porcelain, in which a groove was cut containing a flat bar of platinum, an inch and three-quarters in length, two-tenths of an inch broad, and one-tenth of an inch thick. One end of the bar abuts against the bottom of the groove, the other presses against the short arm of a bent lever, of which the long arm, moving on a pivot, becomes the index of the instrument and marks the degrees on a scale fixed to the porcelain. Guyton connected these degrees with those of the ordinary mercurial thermometer, and accordingly was able to give in Fahrenheit degrees the fusing points of various metals. As we have already noticed, he corrected Wedgwood's scale, which, thus altered, furnished a table of high temperatures, far nearer the truth than it was originally.

Daniell, unaware of Guyton's pyrometer, invented one on somewhat the same principle, but certainly more trustworthy in its indications. In this pyrometer a mixture of black lead and clay was substituted for the porcelain in the former; the part by which the heat was to be determined being in Daniell's original instrument a rod of platinum, ten inches in length and a seventh of an inch in diameter, placed within a tube of black-lead ware, and having one end fixed at the bottom of the tube; to the other end was attached a fine wire of platinum, which, after passing two or three times round the axis of a wheel, was fastened to a spring by which it was always preserved at the same degree of tension. The teeth of the wheel played into a pinion, the axis of which carried an index, whose revolution showed, on a greatly magnified scale, the expansion and contraction of the platinum rod.

In 1830 Daniell improved his pyrometer by dividing it into two parts, one of which he termed the *register*, the other the *scale*. The *register* was the part exposed to the temperature to be determined, and consisted of a rod of metal, generally wrought iron, dropped within a tube of black lead. The heat expanded the metal more than the plumbago, and the *scale*, by a rule and vernier, measured this relative expansibility of the platinum. Reducing his scale by experiment to that of Fahrenheit, Daniell determined the fusing point of several metals; the results of some of his experiments are given in the article TEMPERATURE.

In a paper read before the Paris Academy of Sciences in 1836, Pouillet proposed three

methods of measuring high temperatures. The first method, which was originally used by Prinsep in 1827, consisted in employing the dilatation of a gas by heat, instead of the expansion of a solid. Pouillet's air pyrometer is a cylindrical vessel of platinum, containing air; connected with the vessel is an exit tube, also of platinum, which leads into a manometer, by the depression of the mercury in which the amount of the expansion of the air in the vessel, when exposed to a high temperature, can be determined. Knowing how much air enlarges in bulk for every degree of temperature, in other words, knowing the coefficient of expansion of air, and having found how much air has been expelled by the source of heat, we are enabled by a simple calculation to find the temperature to which the pyrometer has been exposed. The second method suggested and used by Pouillet was the production of a thermo-electric current by the union of platinum and iron, the junction being exposed to the source of heat. Equal increments of heat were found up to a high limit to produce equal additions to the strength of the current. By means of a tangent galvanometer the strength of the thermo-electric current could be accurately measured, and in this way Pouillet succeeded in finding the fusing points of a number of metals; the results obtained by his two pyrometers agreeing fairly. With the same instruments as those here described, Pouillet subsequently determined very low temperatures, with great accordance in the different means of measurement. The third means of measuring high degrees of heat, suggested by Pouillet, differs in its principle from other pyrometers. The difference between the specific heat of platinum and water is employed to determine the temperature to which the former has been raised. The specific heat of water being 1, that of platinum at high temperatures is ·0373; in order, therefore, to raise an ounce of water one degree, about 28 times more heat is needed than to raise an equal weight of platinum to the same temperature. If 200 ounces of platinum heated in a furnace raise 1,000 ounces of water 12½°, it can readily be found that the temperature of the platinum before immersion was 1756°. In this way Pouillet has determined some high temperatures, and the principle has been suggested for use in certain arts, employing a copper ball instead of platinum; it requires, however, skill and repetition to avoid several sources of error.

Owing to the investigations of Regnault, our knowledge of the rate of expansion of gases has of late become far more accurate. This circumstance, and the improvements in the apparatus made by Regnault, greatly increased the value of measurements made by the air pyrometer. But, quite recently, doubts of the accuracy of the indications of this instrument have arisen from an unexpected cause. In the course of his researches, M. H. St. Cl. Deville discovered that platinum and iron, to a certain extent, become porous when at a white heat. A platinum vessel, therefore, containing air, or still more hydrogen, would at a high temperature permit the passage of a portion of the enclosed gas through its substance; hence, as experimentally established by Deville and Troost, this becomes a serious source of error, to which air pyrometers made of these metals have all been exposed. Deville and Troost, in a series of measurements of high temperatures, have advantageously replaced air by the vapour of iodine, or of that of some of the metals; using, moreover, instead of platinum a vessel of porcelain.

M. Ed. Becquerel has recently made some researches on the measurement of high temperatures, which are published in the *Comptes Rendus* of the Paris Academy for December 1862 and November 1863. M. Becquerel's pyrometer is a thermo-electric couple formed by the union of a wire of platinum with another of palladium; the current generated regularly increasing with the temperature up to the fusion of palladium at about 1500° C. = 2730° Fahr. Observations with this pyrometer caused M. Becquerel to suggest an *optical* pyrometer; a means of determining any temperature, however elevated, by measuring the intensity of the light emitted from the glowing source. The point of fusion of platinum he thus estimates at 1600° C. or 2910° Fahr., and the temperature of the positive carbon in the voltaic arc at 2070° C. or 3760° Fahr. M. Becquerel has, by means of the thermo-electric and air pyrometer, determined the boiling points of some of the metals. The correctness of the numbers which he obtained has, however, been disputed.

Under the article TEMPERATURE the measurements of various high temperatures obtained by different experiments are given at length.

Pyromorphite (Gr. πῦρ, and μορφή, *form*). Native chloro-phosphate of lead, found at Huel Penrose, and other Cornish mines, and in Devonshire, Derbyshire, Cumberland, and Leadhills in Lanarkshire. When heated before the blowpipe, it fuses into a globule, and the name has reference to the polyhedral crystalline form which such a globule assumes in cooling.

Pyrope (Gr. πῦρ, and ὄψις, *appearance*). Precious Garnet. A dark red variety of Garnet seldom found crystallised, but generally in rounded or angular grains. This stone, which is of a full crimson-red colour, approaching to that of a ripe mulberry, is much used in jewellery. Sometimes it is called *fire garnet*, from the resemblance of its hue, when held between the eye and the light, to that of a burning coal. It is procured chiefly from Bohemia, Saxony, and Ceylon.

Pyrophane (Gr. πῦρ, and φαίνομαι, *to appear*). A variety of semi-opal which becomes transparent on being heated.

Pyrophorus (Gr. πῦρ, and φέρω, *I bear*). A substance which spontaneously takes fire when exposed to air. *Homberg's* pyrophorus is made by mixing equal weights of alum and

brown sugar, and stirring the mixture over the fire in an iron ladle till quite dry; it is then put into an earthen or coated glass bottle, and heated red-hot so long as a flame appears at the mouth; it is then removed, carefully stopped, and suffered to cool. The black powder which it contains becomes glowing hot when exposed for a few minutes to the air. The experiment succeeds best in a damp state of the atmosphere, and the ignition is frequently accelerated by breathing upon the powder. A mixture of 3 parts of lampblack, 4 of dried alum, and 8 of carbonate of potassa, may be substituted for the above, and calcined in the same way: 27 parts of sulphate of potassa and 15 of calcined lampblack, heated to redness in a crucible, and then carefully preserved out of contact of air, also yield a good pyrophorus.

It appears from Gay Lussac's experiments that the essential ingredient in these pyrophori is sulphuret of potassium; the charcoal and alumina only act by being interposed between its particles; but, when the mass once kindles, the charcoal takes fire and prolongs the combustion. An excellent pyrophorus is afforded by heating tartrate of lead red-hot in a glass tube, in which it may afterwards be hermetically sealed. When the tube is broken, and the black powder within it shaken out through the air, it burns with the emission of a dense smoke of oxide of lead. The spontaneous inflammability of this pyrophorus is probably due to minutely divided lead.

Pyrophyllite (from Gr. πῦρ, and φύλλον, *a leaf*; as exfoliating before the blowpipe). A hydrated silicate of alumina of a white or a pale green colour. It occurs foliated like talc (which it was formerly supposed to be), and often in fibrous radiated masses, and small elongated prisms, in the Ural, at Westana in Sweden, and at Cottonstone Mountain, North Carolina, also in Georgia and California.

Pyrophysalite (Gr. πῦρ, and φυσαλίς, *a bubble*). A coarse and nearly opaque variety of Topaz, found occasionally in large yellowish-white crystals at Finbo and Broddbo in Sweden.

Pyropissite (Gr. πῦρ, and πίσσα, *pitch*). A mineral resin, resembling earthy brown coal in appearance, met with at Weissenfels in Prussia.

Pyrorthite (Gr. πῦρ, and ὀρθός, *straight*). Probably a decomposed Orthite, containing bituminous matter, found in granite at Kararfoet near Fahlun in Sweden. When gently heated on one side it takes fire and burns; hence the name.

Pyrosiderite. [PYRRHOSIDERITE.]

Pyrrhosiderite (Gr. πυῤῥός, *brown*, and σίδηρος, *iron*). A brown hydrous peroxide of iron (Göthite) from Eiserfeld in Nassau.

Pyrosis (Gr. πύρωσις, from πυρόω, *I set on fire*). A disease of the stomach, attended by a burning sensation, and the throwing up of a quantity of saline fluid; it is sometimes called *water brash* and *black water*.

Pyrosklerite (Gr. πῦρ, and σκληρός, *hard*; from its refractory behaviour before the blowpipe). A green or reddish hydrated silicate of magnesia and alumina, found in foliated and fibrous masses at Elba, and at Åker in Sudermannland, Sweden.

Pyrosmalite (Gr. πῦρ; ὀσμή, *odour*; and λίθος, *stone*). A native silicate of iron, with chloride of iron, which, when heated, exhales the odour of chlorine. It occurs massive, and in six-sided prisms, at Nya Kopparberg in Sweden, and at one of the iron mines of Nordmark near Phillipstad.

Pyrosoma (Gr. πῦρ, and σῶμα, *a body*). The generic name of certain pelagic floating compound Ascidians, remarkable for the brilliant phosphoric luminosity which they emit.

Pyrotechny (Gr. πῦρ, and τέχνη, *art*). This term denotes, in its widest sense, the art or science which teaches the management and application of fire to certain operations; but it is most usually restricted to those articles and instruments manufactured for amusement, or for exhibition on grand public occasions. The origin of artificial fireworks is lost in obscurity. They were in general use in China long before their introduction to Europe, which is comparatively of recent date. The finest inventions of this kind are due to the celebrated Ruggieri, father and son, who executed in Rome and Paris, and the principal capitals of Europe, the most brilliant fireworks ever seen.

Fireworks are divided into three classes:—
1. Those to be set off upon the ground;
2. Those which are shot up into the air; and
3. Those which act upon or under water.

The three prime materials of their composition are, nitre, sulphur, and charcoal, along with filings of iron, steel, copper, zinc, and resin, camphor, lycopodium, &c. Gunpowder is used either in grain, half crushed, or finely ground, for different purposes. The longer the iron filings, the brighter red and white sparks they give; those being preferred which are made with a very coarse file and quite free from rust. Steel filings and cast-iron borings contain carbon, and afford a more brilliant fire with wavy radiations. Copper filings give a greenish tint to flame, those of zinc a fine blue colour; the sulphuret of antimony gives a less greenish blue than zinc, but with much smoke; amber affords a yellow fire, as well as colophony and common salt; but the last must be very dry. Lampblack produces a very red colour with gunpowder, and a pink with nitre in excess. It serves for making golden showers. The yellow sand or glistening mica communicates to fireworks golden radiations. Verdigris imparts a pale green; sulphate of copper and sal-ammoniac, a palm-tree green. Camphor yields a very white flame and aromatic fumes, which mask the bad smell of other substances. Benzoin and storax are used also on account of their agreeable odour. Lycopodium burns with a rose colour and a magnificent flame; it is principally employed in theatres to represent lightning, or to charge the torch of a fury. (See, for full information as to the

various processes adopted in the construction of fireworks, Ure's *Dictionary of Arts, &c.* art. 'Fireworks.')

Chinese or Japanese Fire.—This composition, which may be either rammed into cases ¼ of an inch in diameter, or folded up in quantities of about 1 or 1½ grain in slips of tissue paper, consists of—

Nitrate of potash	3¼ parts
Sulphur	1½ part
Lampblack	1 „

These ingredients should be well incorporated, after being first passed through a fine sieve. If put into a case, the mixture burns slowly, throwing out splendid coruscating sparks which, from some fancied resemblance to the rowel of a spur, caused this mixture to be formerly called *spur fire.* These magnificent sparks are perhaps seen to best advantage when the composition is enclosed in tissue paper, as above described. These charged papers have recently become known under the name of *Japanese matches.*

PYROTECHNY. In Military Art, the science of the manufacture of artificial fireworks, and all combustible materials, including the compositions for rockets, fuses, carcasses, &c. &c., together with their use and application.

Pyroxanthin (Gr. πῦρ, and ξανθός, *yellow*). A crystalline yellow derivative of the action of alkalies upon wood-tar.

Pyroxene (Gr. πῦρ, and ξένος, *a guest*). A mineral isomorphous with Hornblende, but differing from it in containing a smaller quantity of silica, in being less fusible, and in having a higher specific gravity. The name indicates that it is a guest in the domain of fire, or that it is supposed to have pre-existed in the lava in which it is contained, and is not therefore a result of crystallisation consequent on the cooling of the mass. [AUGITE.]

Pyroxylic Spirit, Wood Spirit, or **Methylic Alcohol.** When wood is subjected to destructive distillation there is formed, besides tar, acetic acid, and other products, a variable portion, but not amounting on an average to more than about 1 per cent., of an inflammable and volatile liquid. This may be separated, to a certain extent, from the water and acetic acid, by distillation and separation of the first products. These, redistilled and rectified over quicklime, afford the *pyroxylic spirit* or *methylic alcohol* of commerce. If it contain ammonia, it should be neutralised, by sulphuric acid, previous to its last rectification. To obtain perfectly pure pyroxylic spirit, an excess of chloride of calcium is added, and the mixture is distilled in a water-bath so long as any volatile matter goes over. A compound of wood-spirit with chloride of calcium remains in the retort, to which a quantity of water, equal to that of the original spirit, is added, and the distillation then continued. The product which is now obtained, and which is pure pyroxylic spirit diluted by a little water, may be dehydrated by a final distillation off quicklime. Pyroxylic spirit is the *alcohol* of the *methylic* series. It is a limpid liquid, of a penetrating odour, partaking of that of alcohol and acetic ether, with an aromatic taint which has been compared to peppermint. Its taste is hot and pungent. Its specific gravity at 60° is 0·7398. It is very inflammable, and burns with a pale flame resembling that of alcohol. It boils at about 150°; the density of its vapour is 1·125. When pure it is not altered by exposure to air or light, but when subjected to the slow action of platinum-black, it yields, together with other products, *formic* acid; not acetic acid, as is the case with alcohol. If pure, it is neutral, and mixes in all proportions with water, alcohol, and ether, without becoming turbid. Its solvent powers, in regard to *salts,* closely resemble those of alcohol; it dissolves the resins, and may be used as a substitute for alcohol in almost all varnishes, but its odour is objectionable. It is a powerful antiseptic, and preservative of animal matter.

Pyroxylic spirit has the formula of $C_2H_4O_2$, or as hydrated oxide of methyl of C_2H_3O,HO or MeO,HO.

Methylated Spirit.—A mixture of 90 per cent. of alcohol and 10 per cent. of methylic alcohol is much used in the arts and manufactures, as well as in medicine and chemistry, as a substitute for rectified spirit.

Pyroxyline. The manufacture of this substance for military purposes, and its composition when so prepared, are noticed under the article GUN COTTON. In the chemical laboratory the following process may be resorted to for its production. Dry and clean carded cotton-wool is steeped in a mixture of three volumes of nitric acid (sp. gr. 1·5) with five of sulphuric acid; the mixture is allowed to cool, and small portions of cotton should be used at a time, so as to avoid elevation of temperature. In ten or twenty minutes the cotton may be withdrawn (the excess of acid pressed out), and thoroughly washed in water containing a little ammonia; it is then cautiously dried, at a temperature not exceeding 200° Fahr. 100 parts of cotton thus treated yield about 177 of dry gun cotton. Clean paper, the purer varieties of sawdust, and other forms of ligneous matter, produce similar compounds. Pyroxylic paper is remarkable for the intensity of its electricity when slightly rubbed. Well-prepared pyroxyline resembles the original cotton in appearance, but is more harsh and brittle, and highly electric. Its extreme combustibility is very remarkable. Inflamed in the open air it flashes off without smoke or residue; it takes fire at a much lower temperature than that required for the ignition of gunpowder, and its combustion is more rapid. The temperature at which gun cotton is inflamed is about 277° Fahr., but the different varieties of it no doubt require different temperatures for their ignition. When substituted for gunpowder in firearms, the extreme suddenness of its explosion would be apt to burst the barrel, unless precautions were

taken to prevent the simultaneous ignition of the whole charge. When this is done, however, it has now been shown that pyroxyline can be safely and with great advantages substituted for gunpowder in fowling-pieces. It is not deteriorated in damp air, or even (when subsequently dried) by immersion in water; and, weight for weight, its explosive force is between three and four times greater than that of gunpowder. The extreme rapidity of its combustion is well shown by placing a flock of it upon a small heap of gunpowder, where it may be exploded by a hot wire without kindling the powder. Aqueous vapour, carbonic oxide, carbonic acid, and nitrogen, are the only products of its combustion in a closed space, but in the open air it forms also traces of nitrous acid.

Under the name of *collodion*, a solution of pyroxyline in a mixture of alcohol and ether is largely used by photographers. For such purposes Mr. Nicol recommends the following formula. Ten ounces, by measure, of sulphuric acid (1·840), and five ounces, by measure, of nitric acid (1·370), are to be well mixed, and two fluid drachms of water added. When the mixture has cooled to about 130°, place in it, tuft by tuft, well pulled out, five drachms of clean cotton. Each tuft should be penetrated by the acid as it is immersed, and kept in for ten minutes, then removed, well washed, and dried. This compound is soluble in a mixture of alcohol and ether, and the solution leaves, on evaporation, a smooth transparent film.

The composition of pyroxyline varies with the mode of preparation. It is generally regarded as a substitution compound in which peroxide of nitrogen (NO_4) replaces one or more atoms of the hydrogen of the cotton-fibre. According to Hadow, the most explosive variety (insoluble in a mixture of alcohol and ether) may be represented by the formula $C_{36}\,O_{30}\,H_{21},+\,9\,NO_4$, and the less explosive variety used in making collodion, and therefore soluble in a mixture of alcohol and ether, as $C_{36}\,O_{30}\,H_{22},+\,8\,NO_4$, so that in the former nine, and in the latter eight, atoms of the hydrogen of the cotton are replaced by peroxide of nitrogen, assuming cotton fibre as $C_{36}\,H_{30}\,O_{30}$.

Pyrrha. In Mythology. [DEUCALION.]

Pyrrhic Dance. A species of warlike dance called by the Romans *Pyrrhica Saltatio*, said to have been invented by Pyrrhus to grace the funeral of his father Achilles. This dance consisted chiefly in such an adroit and nimble turning of the body as represented an attempt to avoid the strokes of an enemy in battle, and the motions necessary to perform it were looked upon as a kind of training for the field of battle. This dance is supposed to be described by Homer as engraved on the shield of Achilles. Lord Byron describes the Suliotes as still performing this dance (*Childe Harold*).

Pyrrhite (Gr. πυῤῥός, *yellow*). A mineral occurring in minute octahedrons of an orange-yellow colour, at Alabaschka in Siberia, and the Azores. It is probably columbate of Zirconia coloured by the oxides of iron, uranium, and manganese.

Pyrrhonists. The followers of Pyrrho, a philosopher of Elis, and disciple of Anaxarchus, who flourished about 300 B.C. Their tenets, which have come to us only through the reports of unfriendly writers, are said to have been so absurdly sceptical, that they would not put even as much confidence in the senses as was necessary for the preservation of their existence; but this seems partly refuted by the age at which Pyrrho himself died, which was ninety years. There is a summary of the doctrines of Pyrrhonism in the 2nd vol. of the historical part of the *Encyc. Metropolitana*; see also Hallam, *Literary History*, part ii. ch. iii. § 17, and ch. iv. § 8, and part iii. ch. iii. § 87. [SCEPTICISM.]

Pyrrhotine (Gr. πυῤῥότης, *redness*). Magnetic Iron Pyrites. A sulphide of iron composed of 60·5 per cent. of iron and 39·5 sulphur. It generally occurs massive and amorphous, but sometimes crystallised, in irregular and variously modified six-sided prisms. The colour, which is bronze-yellow, reddish, or brownish, is liable to become speedily tarnished on exposure to the air. It is found in Cornwall, Devonshire, and Cumberland, in North Wales, and Scotland. In Ireland it is met with of a bronze colour near Leahtown, Donegal. [MAGNETIC PYRITES.]

Pyrrol. An empyreumatic oil formed during the destructive distillation of bone.

Pyrus (Lat. pirus, *a pear-tree*). The genus of *Pomaceæ* or *Rosaceæ*, to which belong the Apple and Pear. In these fruits the ovaries become united, and form with the calyx-tube a fleshy mass enclosing about five leathery or cartilaginous cells, within which are one or two pips. This consistence of the cells is the chief distinction between *Pyrus* and *Cratægus*, the cells of the latter being hard and bony. Besides the Apple, *P. Malus*, and Pear, *P. communis*, the genus includes the Service-tree, *P. Sorbus*, the White Beam-tree, *P. Aria*, and the Mountain Ash or Rowan, *P. Aucuparia*. From the fruit of the latter a jelly is made which is highly esteemed as an adjunct to venison. [APPLE; PEAR.]

Pyruvic Acid. An acid discovered by Berzelius amongst the products of the destructive distillation of racemic and of tartaric acid.

Pythagorean Theorem. In Geometry, the theorem which forms the forty-seventh proposition of Euclid's first book, and according to which the sum of the squares on the sides of a right-angled triangle is equal to the square on the hypothenuse.

Pythagoreans. The followers of Pythagoras, a native of Samos, said to have been the first Greek who assumed the title of a philosopher. The date of his birth and the extent of his scientific travels are matters of great uncertainty (Sir G. C. Lewis, *On the Credibility of Early Roman History*, vol. i.

p. 451; *Astronomy of the Ancients*, 123–269); but he is said finally to have fixed his abode at Crotona, one of the Dorian colonies in the south of Italy. He here attached to himself a large number of youths of noble descent, whom he formed into a secret fraternity for religious and political as well as philosophical purposes; and by their assistance produced many beneficial changes in the institutions of Croton and the other Græco-Italian cities. Of the strictly philosophical tenets of the Pythagoreans very imperfect records are preserved. Many of the doctrines ordinarily imputed to them are evidently the fabrication of the later Pythagoreans, a class of visionaries who lived during the decline of the Roman empire. One point is sufficiently evident, that the Pythagoreans were the greatest mathematicians of their time, and that they sought in the study of mathematical relations that solution of the principal philosophical problems for which their contemporaries, the Ionic and Eleatic philosophers, sought, the first in physical, the others in ontological hypotheses. The relations of space and quantity, as they are the most obvious, are also the most definite forms, in which the laws of the outward world can present themselves to this faculty. Hence, as the atomic philosophers have endeavoured to explain all things by a diversity in the figure of their ultimate parts, the Pythagoreans seem to have found, in the number and proportions of those parts, the true essence of the things themselves. Having proceeded thus far, they went a step farther. They perceived that the universe and its parts are obedient to certain laws, and that these laws can be expressed by numbers. By a mistake prevalent during every period of speculation, they mistook the necessary conditions of a thing's subsistence for the essence of that thing itself; and at once pronounced that numerical relations were not merely all that could be understood in outward phenomena, but were, in fact, all that was real in them. Units of number grew gradually into points in space, and these into material atoms. To every order of existence, even to many abstract conceptions, a distinct number was assigned. God is represented as the original unity; the human soul, the earth, the planets, the animal creation have each their own peculiar arithmetical essence; as have also the abstractions *justice*, *opportunity*, *opinion*, &c.

The outlines of a duallistic scheme are discernible in a singular table of opposites (*συστοιχία*), preserved to us by Aristotle, in which the two principles of the universe are successively represented under the form of limit and the unlimited, odd and even, one and many, right and left, male and female, still and moved, straight and curved, light and darkness, good and evil, square and oblong.

For the character and working of the Pythagorean brotherhoods, see Grote's *History of Greece*, part ii. ch. xxxvii. An account of the astronomical theories of Pythagoras and his followers is given by Sir G. C. Lewis, *Astronomy of the Ancients*, p. 13, &c. See also Thirlwall's *History of Greece*, vol. ii. c. xii.; Ritter's *History of Philosophy*, b. iv.; Boeckh's *Philolaus*, &c.

The doctrine of Metempsychosis, or the transmigration of souls through different orders of animal existence, is the main feature by which the Pythagorean philosophy is popularly known. It is, however, by no means certain that the genuine Pythagoreans held this doctrine in a literal sense. It may have been only a mythical way of communicating their belief in the individuality of the soul and its existence after death.

Pythia (Gr.). The name of the priestess of the Delphian oracle of Apollo. [Oracle.]

Pythian Games. One of the four great national festivals of Greece, celebrated every fifth year in honour of Apollo, near Delphi. Their institution is variously referred to Amphictyon, son of Deucalion, founder of the council of Amphictyons, and Diomedes, son of Tydeus; but the most common legend is that they were founded by Apollo himself, after he had overcome the dragon Python. The contests were the same as those at Olympia, and the victors were rewarded with apples and garlands of laurel. [Delphi.]

Python (Πύθων). In Greek Mythology, the name of the dragon slain by Apollo. [Phœbus; Perseus.] The name was interpreted by the word πύθω, *to rot*, because its dead body was left to rot at Delphi; but this explanation is of no more value than that which professes to account for the name Lycaon. [Rishis.] In Teutonic myths, Python reappears as Fafnir. [Mythology, Comparative; Œdipus; Persephonê; Sigurdr.]

Python. In Zoology, the name of a genus of large Ophidian reptiles, having anal hooks, and a double series of sub-caudal scutæ.

Pyx (Gr. πυξίς, *a box of box-wood*). The name given to the box in which the host is kept by the Roman Catholic priesthood.

Pyx, Trial of. [Coinage.]

Pyxidium (Gr. πυξίδιον, dim. of πυξίς). In Botany, a fruit which divides circularly into a lower and upper half, of which the latter acts as a kind of lid, as in the Pimpernel.

Pyxis Nautica. The Mariner's Compass. A constellation of the southern hemisphere formed by Lacaille.

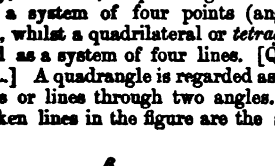
Q

Q. In all the languages in which it is used this letter is invariably followed by *u*, the combination being represented in English pronunciation by the letters *kw*, as in *quote*. Q is used as an abbreviation for *question*; Qy. for *query*; Q. E. D. for *quod erat demonstrandum*, which was to be demonstrated, &c.

Quader Sandstone. The cretaceous rocks of the north of Germany chiefly consist of sandstones, called *Quader sandstones*. There are two divisions—the *Upper Quader*, corresponding nearly in geological age to the main body of the chalk in England and Europe, and the *Lower Quader*, which represents our upper greensand and firestone. These German beds are not without calcareous matter, but it is chiefly present as a cementing medium. They are fossiliferous towards the base. Parts of them are much used as building material, and are well adapted for this purpose.

Quadragesima (Lat. *fortieth*). In the Calendar, a term applied to the time of Lent, because it consists of about forty days. *Quadragesima* Sunday is the first Sunday in Lent, and about the fortieth day before Easter.

Quadrangle (Lat. quadrangulus, *four-cornered*). A figure with four angles and four sides; in short, a quadrilateral. This is the ordinary acceptation of the term. In modern geometry, however, a quadrangle or *tetragon* denotes a system of four points (angles or corners), whilst a quadrilateral or *tetragram* is regarded as a system of four lines. [QUADRILATERAL.] A quadrangle is regarded as having six sides or lines through two angles. Thus the broken lines in the figure are the sides of



the quadrangle a, b, c, d, and α, β, γ, are the three *intersections of opposite sides*, which latter are sometimes called the *diagonal points* of the complete quadrangle. One of the most important properties of the quadrangle is that the rays joining any one of these three diagonal points with the other two are harmonic conjugates with respect to the sides which pass through the first point. Thus $\alpha\,(a\,b\,\beta\,\gamma)$, $\beta\,(a\,b\,\gamma\,\alpha)$, $\gamma\,(a\,d\,\alpha\,\beta)$ are harmonic pencils.

Quadrans (Lat.). A division of the Roman *as*, consisting of one-fourth of it, or three ounces when the *as* was of its full weight. [AS; FARTHING; PENNY; TRIUNCIUS.]

Quadrant. A mathematical instrument, formerly much used in astronomy and navigation. The instrument is variously contrived and fitted up, according to the purpose for which it is intended; but it consists essentially of a limb or arc of a circle equal to the fourth of the circumference, and divided into 90°, with subdivisions. The mural quadrant is of considerable size (six or eight feet radius, for example), the axis of which moves in a wall or solid piece of masonry. [MURAL CIRCLE.] Ptolemy, in the *Almagest*, describes a quadrant with which he determined the obliquity of the ecliptic. Tycho Brahe had a large mural quadrant for observing altitudes, and others which revolved on a vertical axis for measuring azimuths. Picart, in his measurement of the earth, used a quadrant for his terrestrial angles. In 1725 a mural quadrant, by Graham, was erected in the Royal Observatory at Greenwich, which, in 1750, was replaced by Bird's quadrant, with which Bradley made his celebrated observations. The quadrant has, however, of late years been entirely superseded by the *mural circle*; it having been found that the circle, on account of the symmetry of its form, and the advantage which it possesses of allowing the readings to be made at different parts of the limb, is an instrument much more to be relied on. [MURAL CIRCLE.] Hadley's *quadrant*, in its principle and application, is the same as the *sextant*, by which it has been superseded. [SEXTANT.] For further information respecting the quadrant, see Lalande, *Astronomie*, s. 2,311; Vince's *Practical Astronomy*; Pearson's *Practical Astronomy*; and the *Penny Cyclopædia*.

QUADRANT. In Geometry, the fourth part of a circle; an arc of ninety degrees.

QUADRANT. In Gunnery, an instrument occasionally used for regulating the elevation of pieces of ordnance. It consists of two bars of wood or brass, at right angles to each other, with an arc between them divided into degrees. A plumb line hangs from the angle at which the bars meet. One of the bars being placed in the bore of the piece, the degree on the arc intersected by the plumb line shows the elevation.

Quadrant of Altitude. An appendix to an artificial globe, consisting of a thin pliable slip of brass, which is applied to the globe, and used as a scale for measuring the distances between points in degrees. It is graduated into 90°, the degrees being of the same length as those on one of the great circles of the globe. At the end where the division terminates a nut is riveted on, and furnished with a screw, by which it is attached to the brass meridian of the globe at any point. This point being placed in the zenith, and the quadrant applied to the globe, its zero coincides with the horizon, and consequently the altitude of any point along its graduated edge is indicated by the corresponding division.

Quadrantal Triangle. In Trigonometry, a spherical triangle which has one side equal to a quarter of a circle, or 90°.

Quadratic Equation. In Algebra, an equation which involves the second, but no higher power of the unknown quantity. The most general form of a quadratic equation is

$$ax^2 + 2bx + c = 0,$$

where a, b, c, denote any positive or negative numbers. This is sometimes called an *adfected* quadratic, in order to distinguish it from the *pure* quadratic, whose form is

$$a'x^2 + c' = 0.$$

The solution of a pure quadratic is obvious; its two roots are $\sqrt{-\frac{c'}{a'}}$ and $-\sqrt{-\frac{c'}{a'}}$, both of which are real or imaginary according as a' and c' have unlike or like signs. To solve an adfected quadratic it is first reduced to the pure form. This may be done by first dividing the equation by the coefficient of x^2, and then adding and subtracting the square of half the coefficient of x. The above equation thus becomes

$$x^2 + 2\frac{b}{a}x + \frac{b^2}{a^2} - \frac{b^2}{a^2} + \frac{c}{a} = 0,$$

$$\text{or } \left(x + \frac{b}{a}\right)^2 = \frac{b^2 - ac}{a^2},$$

whose roots are obviously $\frac{-b + \sqrt{b^2 - ac}}{a}$ and $\frac{-b - \sqrt{b^2 - ac}}{a}$.

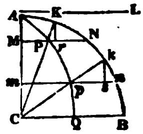
The sum of these roots is seen to be $-\frac{2b}{a}$ and their product $\frac{c}{a}$. This property is a general one [THEORY OF EQUATIONS], and from it is deduced the following simple rule for forming the quadratic whose roots are two given numbers. For the absolute term of the equation, take the product of the given roots, for the coefficient of x take the negative sum of these roots, and let x^2 have the coefficient unity. Thus the equation whose roots are 2 and -3 is

$$x^2 + x - 6 = 0.$$

The expression $b^2 - ac$, under the radical sign, is called the *discriminant* of the equation. When it has a positive value, the roots are real and unequal; when it vanishes, the two roots are real and equal; and when it has a negative value, these roots are impossible or *imaginary*. [DISCRIMINANT.]

Quadratic Form. [QUADRIC.]

Quadratrix. In Geometry, a transcendental curve, by means of which the quadrature of curvilinear spaces can be determined mechanically. The best known of these curves is the *Quadratrix of Dinostratus*, so called from its reputed inventor, a brother of Menechmus and disciple of Plato. This curve is generated as follows:—



In the circular quadrant C A B, suppose the radius C A to revolve uniformly about C, passing through the different positions C K, C k, &c., till it arrives at the position C B; and that during the same time a line A L, at right angles to C A, moves parallel to itself with a uniform motion from the position A L, through the different positions M N, $m\,n$, &c., so as to arrive at C B at the same instant that C K coincides with C B; then the continual intersection of the revolving radius and the parallel line will trace the quadratrix A P Q.

From this mode of describing the curve, it is easy to see how it may be applied to divide an angle into any number of equal parts. Let it be required, for example, to trisect the angle A C k. Having applied the quadratrix to C A, take A M equal to a third of A m, and through M draw M N perpendicular to A C, meeting the curve in P; join C P, and the angle A C P is equal to one-third of A C k; for by the nature of the quadratrix A M : A m : : A K : A k.

The application of this curve to the quadrature of the circle depends on the property that the line C Q is a third proportional to the quadrantal arc A B, and the radius. Hence the arc $AB = \frac{CB^2}{CQ}$, and consequently the area of the quadrant $CAB = \frac{CB^3}{2\,CQ}$.

If the quadratrix be continued beyond A, without the circle, it will consist of a series of infinite hyperbolic branches, cutting the axis C A produced, in points which are separated from each other by a space equal to 2 A C.

Other curves may be formed in a similar manner, by which the quadrature of the circle would be obtained. Thus, instead of supposing the lines M N, $m\,n$ to be intersected by the radiants C K, C k, we may suppose straight lines drawn from K k parallel to A C, intersecting M N, $m\,n$ in r and s; these intersections form a different curve, which is called the *Quadratrix of Tschirnhausen.*

Let $AM = x$, $MP = y$, and $AC = a$; then since $x : a :: AK : AB$, or $\frac{1}{2}\pi$, we have $AK = \frac{\pi x}{2a}$. Hence the equation of the quadratrix of Dinostratus is

$$y = (a - x)\tan\frac{\pi x}{2a};$$

and that of the quadratrix of Tschirnhausen is $y = a \sin\frac{\pi x}{2a}$. (Montucla, *Histoirè des Mathématiques*; Peacock's *Collection of Examples*; Leslie's *Geometry of Curve Lines.*)

Quadrats (Lat. quadratus, *squared*). In Printing, pieces of metal of the depth of the body of the respective sizes of types, and lower

than the types themselves, so that they leave a blank space on the paper when printed. An *en* quadrat is in thickness half the depth, an *em* equal in thickness and depth, a *two-em* quadrat twice the depth, &c. They are used to fill out short lines, form white lines, &c.

Quadrature (Lat. quadratum, *a quartering*). In Astronomy, this term denotes the position of the moon when she is 90° from the sun, or at one of the two points of her orbit equally distant from the conjunction and opposition.

QUADRATURE. In Geometry, this word signifies the determination of the area of a curve, or finding an equal square. The differential element of the area of a curve referred to rectangular coordinates is $y\,dx$; and since y is given in terms of x by the equation of the curve of which the area is proposed to be found, the problem of quadratures in general reduces itself to the integration of the differential $X\,dx$, in which X is an algebraic function of x and known quantities. In the applications of the higher geometry, a problem is conceived to be resolved when it is reduced to quadratures; i.e. when the variable quantities have been separated, and its solution been made to depend on finding the values of one or more integrals of the form $\int X\,dx$.

The *quadrature of the circle* is a problem of great celebrity in the history of mathematical science. The whole circular area being equal to the rectangle under the radius, and a straight line equal to half the circumference, the quadrature would be obtained if the length of the circumference were assigned; and hence the particular object aimed at in attempting to square the circle is the determination of the ratio of the circumference to the diameter. This ratio can be expressed only by infinite series, of which many have been given that converge with great rapidity. [CIRCLE.]

Pretenders to the discovery of the quadrature of the circle occasionally present themselves even at the present day. They are to be found only among those who have an imperfect knowledge of the principles of geometry; and when their reasoning happens to be intelligible, their paralogisms are in general easily detected. With a view to discourage the futile attempts so frequently made on this and similar subjects, the Academy of Sciences of Paris, in 1775, and the Royal Society shortly after, publicly announced that they would not examine in future any paper pretending to the quadrature of the circle, the trisection of an angle, the duplication of the cube, or the discovery of the perpetual motion. For the history of this famous problem, see the third supplement to the fourth volume of Montucla.

Quadri-hydrocarbon. A liquid hydrocarbon of the same chemical constitution as olefiant gas, and containing eight atoms of carbon united with eight atoms of hydrogen. Formerly it was supposed to contain only half this number of atoms of each element. Hence the name.

Quadric. In Algebra, a homogeneous expression of the second degree in the variables or facients. [QUANTIC.] Ternary and quaternary quadrics, equated to zero, represent respectively curves and surfaces which have the property of cutting every line in the plane or in space in two points, and to which the name *quadric* is also applied. Plane quadrics, therefore, are identical with the conic sections, and admit of three principal forms, the *ellipse*, *hyperbola*, and *parabola*; subforms of which are the *circle*, a pair of *intersecting*, and a *pair of coincident lines*. [CONIC SECTIONS.] The ellipse is characterised as being a closed curve, the hyperbola as having two distinct points at infinity, and consequently two real asymptotes, and the parabola as having two coincident points at infinity, and therefore an infinitely distant tangent. A plane quadric may also be regarded as the locus of the intersections of corresponding rays of two homographic pencils [PENCIL], or as the envelope of the line joining corresponding points of two homographic divisions. [HOMOGRAPHIC.] The envelope in the last case can easily be shown to be of the second class. For if a and a_1 be two corresponding points on the homographically divided lines A and A_1, and o any other point in the plane, $o\,a$ and $o\,a_1$ will clearly be corresponding rays of two concentric pencils, which latter will, of course, have two *common rays*; so that of the tangents $a\,a_1$ to the envelope two will in general pass through an arbitrary point o. To prove that such an envelope of the second class is also a quadric or curve of the second order, it is necessary to show that two pairs of consecutive tangents intersect at two points of a given arbitrary line L. To do so, conceive any point m on L, and let the two tangents through m cut A in a and α; then as m changes, a and α will clearly determine an involution of the second order on A [INVOLUTION], which will of course possess two double points, to which will correspond on L two distinct intersections of consecutive tangents, in other words two points on the envelope. Since a plane can always be drawn through three points of a non-plane curve, it is manifest that there are no non-plane quadric curves.

Quadric surfaces are classified in various ways. The *central quadrics*, or those which have centres, are the *ellipsoid* and the *hyperboloids* of one and two sheets, respectively, to which may be added the *cone*. The *non-central quadrics* are the *elliptic* and *hyperbolic paraboloids*, to which may be added the several *cylinders*, distinguished as *elliptic*, *hyperbolic*, or *parabolic*, according to the nature of their sections. All plane sections of the ellipsoid are ellipses, and those of the hyperboloids are either ellipses or hyperbolas. The paraboloids, besides having plane parabolic sections, have either elliptic or hyperbolic ones, and are named accordingly. Besides the cone and cylinders there are two quadric *ruled surfaces*,

the hyperboloid of one continuous sheet, and the hyperbolic paraboloid, each of which may be generated by a line which moves so as to rest on three rectilinear directrices which do not intersect one another. [Ruled Surface.] If the three directrices are parallel to one and the same plane, then the generator will always remain parallel to another plane, and the generated quadric will be a hyperbolic paraboloid; in other cases it will be a hyperboloid. If the two planes, to which the directrices and generator are respectively parallel, be at right angles to each other, the paraboloid is said to be *equilateral*; it is in fact a *conoid* surface, since it may be generated by the motion of a line resting on two directrices to one of which it is always perpendicular. [Conoid.] Every plane through a generator of a quadric ruled surface meets the latter in a second line, and touches it at the point where the lines intersect each other; so that at every point of a ruled quadric a straight edge can be applied to the surface in two distinct directions, and the whole surface is filled, as it were, by two systems of lines or *generators* such that each generator meets no generator of its own system, but cuts every generator of the other system. The distinctive character of the paraboloid is that one generator in each system is infinitely distant. In the hyperboloid the generators are all parallel to those of a quadric cone, the *asymptotic cone*; in the paraboloid they are parallel to a system of two planes, the *asymptotic planes*. Ruled quadrics may also be regarded as the locus of the line which joins corresponding points of two homographically divided lines not in the same plane. If the lines are divided proportionally the quadric will be a paraboloid; or lastly a ruled quadric may be regarded as generated by the intersections of corresponding planes of two homographic pencils whose axes are not in the same plane. From these modes of generation it is at once evident that every plane cuts the generated surface in a quadric curve, and that the tangent planes through any point in space envelope a quadric cone; in other words, that the surface is of the second order and second class.

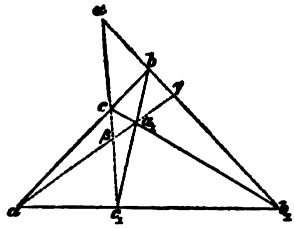
Quadric Cone. A cone of the second order. [Cone.]

Quadricorns (Lat. quatuor, *four*; cornu, *a horn*). A family of Apterous insects, comprehending those which have four antennæ. A species of Antelope with four horns is called *Antilope* (*Tetracerus*) *quadricornis*.

Quadrifores (Lat. quatuor, and foro, *I pierce*). A name given by Latreille to a family of sessile Cirripeds, comprehending those in which the opercular covering of the tube is composed of four valves or calcareous pieces.

Quadriga (Lat. contracted from quadrijuga, *a team of four animals*). In Roman Antiquities, a car or chariot drawn by four horses, which were harnessed all abreast, and not in pairs. The quadriga is often met with on the reverse of medals, which are thence termed *nummi quadrigati* or *victoriati*, as exhibiting a representation of a figure of Victory holding the reins.

Quadrilateral (Lat. quadrilaterus, *of four sides*). In Elementary Geometry, a plane figure contained by four straight lines. Such a figure has four angles or corners, and is consequently also a *quadrangle*. The lines joining its oppo-



site corners constitute its *two diagonals*. In modern geometry, however, a *quadrilateral* or *tetragon* denotes a system of four lines (sides); whilst by *quadrangle* is usually meant a system of four points (angles). The former has six angles or points in two sides, and the latter has six sides or lines through two points. If the full lines in the figure represent any *complete quadrilateral*, the broken lines $a\,a_1$, $b\,b_1$, $c\,c_1$, joining the three pairs of opposite angles, constitute its *three diagonals*. One of the most important properties of a complete quadrilateral is that each diagonal is cut by the other two in harmonic conjugates with respect to the two angles which it contains. Thus a, a_1, β, γ; b, b_1, γ, α; c, c_1, α, β, are four sets of harmonical points.

Four lines in space, two of which, though not in the same plane, are intersected by each of the others, form a *skew quadrilateral*.

Quadrilateral. This name has been used, in the recent struggles between the Italians and the Austrians, to denote the territory, which forms a sort of square, between the fortresses of Peschiera, Verona, Legnano, and Mantua.

Quadrilaterals. The name of a tribe of crabs (Brachyurous Crustaceans), comprehending those in which the carapace or shell is more or less square-shaped.

Quadrille (Fr.). A game at cards for four persons, having some resemblance to whist. It was very popular and fashionable in England some two generations back, but is now almost f rgotten. It ought to be revived, for it has reat merits. It demands less science, thought, and memory than whist; but still it gives ample scope for skilful play, and it is much more varied, amusing, and suitable for younger players. It is a highly original game, having some peculiar features, and therefore requires a little attention from beginners; but the peculiarities are soon mastered, and are easily remembered.

Quadrille is played with a pack of forty cards, the eight, nine, and ten of each suit being rejected. The dealing and order of playing are similar to whist; except (1) that they go the *contrary way round*, the person at the right of

the dealer being elder hand; (2) that the cards must be dealt in parcels of twos, threes, and a four to each person, and not singly; and (3) that no trump is turned up, the trump suit being determined in another way. It is advisable not to shuffle the cards between the deals, but merely to cut them.

The order of value of the cards is peculiar, being different in the two colours, and being also quite exceptional in regard to the suit of trumps. For suits *not trumps* the order is as follows:—

Red Suits	*Black Suits*
King (highest)	King (highest)
Queen	Queen
Knave	Knave
Ace	—
Two	Seven
Three	Six
Four	Five
Five	Four
Six	Three
Seven (lowest)	Two (lowest)

For the *trump* suit the order of value is as follows:—

First comes the ace of spades, which, *whatever be the trump suit*, is always ranked as the best trump card, and is called *spadille*.

Second in rank comes what would be the lowest card if the suit were not trumps, i. e. the seven if red, and the two if black; this is called *manille*.

Third comes the ace of clubs, which, whatever be the trump suit, is always ranked as the third best trump card, and is called *basto*.

Fourth, if the trump suit be red, comes the ace of the trump suit, called *ponto*; if black, there is no ponto.

After these come the other cards of the trump suit in their usual order, so that the complete suit of trumps is as follows:—

If Red	*If Black*
Ace of spades (*spadille*)	Ace of spades (*spadille*)
Seven (*manille*)	Two (*manille*)
Ace of clubs (*basto*)	Ace of clubs (*basto*)
Ace (*ponto*)	King
King	Queen
Queen	Knave
Knave	Seven
Two	Six
Three	Five
Four	Four
Five	Three (lowest)
Six (lowest)	

It will be seen that there are twelve trumps when the suit is red, but only eleven when black.

The three best trump cards, with the special names, are called *matadores*, or shortly *mats*. They have the privilege that the holder is not bound to follow suit with them when trumps are led, except when the card led is a higher mat, which forces a lower one, if there is no other trump in the hand.

The cards being dealt round, and the players having examined their hands, a decision is come to about trumps and partners in the following manner.

The elder hand has the first option of nominating trumps and playing for the game; and he has also the power of deciding whether he will play alone against the other three, or will take a partner. His choice will be regulated by the nature of his hand.

First, let us suppose he has a very strong hand in one particular suit, say diamonds, and has also other good cards, so as to be able by himself to make *six tricks*, which is the object of the game; he says, 'I play alone with diamonds for trumps,' or, 'I play alone in diamonds.' From this there is no appeal, and the game proceeds on his proposition.

But secondly, suppose he has a moderately strong hand in one suit, so that he can probably make *four tricks*, he decides to take a partner to help him by getting two, and he then says, 'I ask leave' (to take a partner). Now, if the second hand, or after him the third or fourth hand, choose to *stand alone* in any suit, they take precedence over the first hand's 'ask leave;' giving *him*, however, the previous option of standing alone if he pleases. If no one makes this proposition, the elder hand, having thus obtained the *leave* he asked, names his trump suit, and calls, for his partner, the player who may hold the *king* of any suit, not trumps, which he chooses to name; he says, for example, 'I make diamonds trumps, and call the king of spades.' The player who holds this card then knows that he is the partner chosen, although he must not reveal this fact except by his play; the other two, of course, know they are opponents, and regulate their play accordingly. If the caller happens to hold all *four* kings in his hand, he may call a queen.

The third alternative for the elder hand is that in which he may have but poor cards, not sufficient to warrant him in playing for the game either alone or with a partner; in which case he says, 'I pass,' and waives his privilege, which passes on to the second player, and from him to the third and fourth in turn. The one who ultimately undertakes the game, and nominates trumps, is called the *ombre*. If the cards are pretty equally divided, all the players may *pass*; and then the one who holds spadille is *forced* to be ombre, and to nominate trumps, calling a king in the usual way. This is called *forced spadille*. Some authorities, however, object to forced spadille, and prefer a fresh deal.

The trumps and partners being decided, play begins for tricks in the same manner as in whist, and subject to the same rules, except as before stated. The elder hand (to the *right* of the dealer) leads first, and the winner of each trick leads for the following one. The object is to win six tricks, called *game*, which *ombre*, either alone or with a partner, undertakes to do; if he makes less, he is said to be *basted*, and has to pay a forfeit, as hereafter explained.

When six tricks have been won by either party, the play is discontinued, unless the winners should choose to undertake to make *all* the ten tricks, which is called *vole*. A player alone would, of course, decide this himself; but if there are partners, the winner of the sixth trick tells his partner how many more tricks he thinks he can make, and the latter then decides whether they will venture it or not. If it is undertaken and not obtained, the parties are punished by forfeits.

Each deal of cards constitutes a complete game.

The game is played with a pool. Each player is furnished with a little tray, and the large tray, or pool, is managed by any one of the four who will undertake it; this being, however, merely a matter of convenience, involving no speculation or risk. The players subscribe equally, on commencing, to form a common fund, which is put into the pool; and, as it is not always convenient to be handing about small *coins*, it is customary to exchange a portion of the fund for counters, which have a certain definite value, and are convertible back again into money at any time throughout the play. When the pool is thus made up, a number of counters are distributed to the players equally, say six to each, to enable them to meet certain payments they may perhaps have to make. We shall take one counter as the constant unit of value.

The transactions are of three kinds—payments from the pool, forfeits to the pool, and payments between the players.

1. The *payments from the pool* are ordinarily *seven counters* each game, viz.

One counter to the holder of each of the red aces.

One counter to the holder of each matadore.

Two counters for winning the game; divided, if won by partners.

2. The *forfeits to the pool* are founded on a principle universally applicable in quadrille, that whoever fails to win what he undertakes must forfeit the sum which he would have obtained if he *had* won; the undertaking being considered in the light of a *wager*. Thus:—

If *player alone* be basted, i.e. make less than six tricks, he forfeits to the pool two counters. If he make only four, the adversaries win; and as *each* of the three is supposed to be equally instrumental in winning, each is accordingly paid one counter from the pool.

If ombre and partner be basted, i.e. make together less than six tricks, two counters are forfeited in like manner to the pool, which must be paid by ombre alone, he being assumed to be the party at fault. If they make only four tricks, the opponents, winning the game, receive from the pool the payment forfeited by ombre.

The mats and red aces are always paid for to the holders, no matter how the game goes.

3. The *payments between the parties*, which are quite distinct and separate from the pool transactions, are as follows:—

If *player alone* win the game, he receives two counters from each of his three adversaries. If he fail to win it, he *pays* two to each.

If *player alone* hold all the three matadores, and win the game, he receives one counter additional from each opponent; but if he fail to win, he *pays* one to each.

If ombre and partner hold between them all the three matadores, and win the game, they each receive one counter from one adversary; if they fail to win, they each *pay* one counter in like manner.

The *vole* is entirely a separate speculation from the game, the rewards and forfeits for it being arranged as follows: If the vole is played for, and won, by two partners, each receives two counters from the pool, and two from one of his adversaries; if lost, the undertakers forfeit to the pool and the adversaries a like sum. If the vole is won by a *player alone*, he is paid four counters from the pool and two by each adversary; if lost, he pays like sums.

We will now give an example of a game for practice and illustration.

An ask leave in a red suit.—Eldest hand has—*Clubs*: queen, knave, six, five; *hearts*: ace; *spades*: six, two; *diamonds*: five, four, two.

Second hand has—*Clubs*: ace; *hearts*: queen, knave, seven, four; *spades*: king, three; *diamonds*: ace, queen, three.

Third hand has—*Clubs*: king, four, three, two; *hearts*: six, five, two; *spades*: queen, knave; *diamonds*: knave.

Fourth hand (the dealer) has—*Clubs*: seven; *hearts*: king, three; *spades*: ace, seven, five, four; *diamonds*: king, seven, six.

First hand passes; his longest suit is clubs, but in that he has the three mats and king against him. In spades he has manille; but that alone, or with one other only, cannot be calculated upon for a trick.

Second hand asks leave in hearts, having manille, basto, queen, knave, and four. He allows for manille falling to spadille, and will make basto, that is one trick. With queen, knave, and four, he must make one, probably two more tricks. The king of spades is a third, and the queen of diamonds is a fourth trick. In order to establish his queen of diamonds, he will *call* the king.

Neither third nor fourth hand can play alone, as it will easily be seen that in no suit could either of them make six tricks; they therefore pass.

The second hand now says, 'I play in hearts, and call the king of diamonds.' Consequently, his partner is the fourth hand.

The lead being with No. 1, he leads a club, say the five; as he has four, he hopes that if ombre (that is, No 2) has the king, his (No. 1's) partner (No. 3) may trump it. At all events, No. 1 will establish his queen and knave of clubs. Ombre sees at once that No. 1 is an adversary; had he been his partner, he would have shown himself either by leading trump, or the called king (diamonds). Ombre, therefore, trumps with the four. No. 3 throws the two, No. 4 the seven.

Ombre now leads the three of diamonds to discover his partner. No. 3 throws the knave; No. 4 the king, discovering himself; No. 1 throws the five, being the worst diamond in his hand.

No. 4 now leads the three of trumps. This play shows ombre that he has a mat, and ombre knows it to be spadille as he himself holds manille and basto. No. 1 is forced to follow suit with ponto; ombre plays basto; No. 3 throws the six.

Ombre leads manille; No. 3 throws the five No. 4 the king; No. 1 small spade.

Ombre, queen of trumps; No. 3, the two; No. 4, seven of diamonds (spadille, in common with other mats, possessing the power of holding up); No. 1, the four of diamonds.

Ombre, knave of trumps; No. 3, three of clubs; No. 4, six of diamonds; No. 1, six of clubs.

The game is now won. The question remains whether ombre and his partner can play the vole. Now ombre knows his partner has spadille, that is, one trick; he himself has three more certain tricks in his hand; he therefore declares to play vole, as follows:—

Ombre, queen of diamonds; No. 3, anything; No. 4, anything; No. 1 follows suit.

Ombre, ace of diamonds; Nos. 3, 4, and 1, anything; ombre, king of spades; Nos. 3, 4, and 1, anything; and spadille must make remaining trick.

As to the payment:—

No. 1 receives from the pool one counter for his ace of hearts; he has to pay to one of his adversaries one counter for their possessing all the mats, and two counters for their playing the vole.

No. 2 (ombre) receives from No. 1 or 3 one counter for mats, and two for vole. From the pool one counter for red ace, one for manille, one for basto, one for game, and two for vole.

No. 3 pays as No. 1.

No. 4 receives from 1 or 3 as No. 2; from pool, one counter for spadille, one for game, two for vole.

What we have above described is the simple game, but it is very customary to play it with a slight modification, called *preference*. In this, one suit, namely hearts, has a preference in the nomination of trumps; thus, if the elder hand has asked leave, the second hand (or after him the third or fourth) may ask him 'if it is in hearts,' and if he says no, the other may ask leave by *preference* in hearts, which takes precedence accordingly. But it must be borne in mind that *standing alone* in any common suit always take precedence of an *ask leave* in the preferred one.

In playing preference, all payments, rewards, and forfeits, are *doubled* when hearts are made trumps.

Sometimes there is a *double* preference, clubs (then called *mogul*) being preferred over hearts, and when these are trumps all payments are quadrupled.

It is also very common to have the option of *purchasing a king*. It may often happen that a player finds that the possession of a certain king, which he has not, would enable him to *play alone*. In this case he may purchase it from the party holding it, giving one counter in payment (subject to increase for preference), and any card which he can best spare from his hand. But if he then win the game he only receives from his adversaries one counter each, instead of two.

We advise the adoption of single preference, and the purchased king, as giving additional interest and variety to the game, without adding to its difficulty.

The celebrated game described in Pope's *Rape of the Lock* was a modification of Quadrille.

Quadrinvariant. [INVARIANT.]

Quadripennates (Lat. quatuor; penna, *a wing*). The name of a section of Anelytrous insects, including those which have four wings.

Quadriplanar Coordinates. [COORDINATES.]

Quadrireme (Lat. quadriremis, from quatuor, and remus, *an oar*). A ship of war in use among the ancient Greeks and Romans; so called because it had four banks of oars. [GALLEY.]

Quadrisulcates (Lat. quatuor, and sulcus, *a furrow*). A name applied to those Ungulate quadrupeds in which the hoof is divided into four parts, corresponding to the four digits of the Artiodactyle foot.

Quadrivium (Lat.). In the language of the schools, the four lesser arts—arithmetic, music, geometry, and astronomy. (Hallam, *Literary History*, pt. i. ch. i. § 3.) [TRIVIUM.]

Quadrumana (Lat. quatuor, *four*, and manus, *hand*). The name of an order of Mammals, comprehending those in which the four extremities are terminated by a hand; as the ape, baboon, &c. The hinder extremities are always terminated by more perfect hands than the fore extremities, in which the thumb is sometimes wanting, or, as in the South American monkeys, incapable of being opposed to the other digits.

Quadrupeds (Lat. quadrupes, from quatuor *four*, and pes, *a foot*). All Vertebrate animals with four extremities fitted for terrestrial progression were formerly so called, the scaly reptiles being distinguished, as oviparous quadrupeds, from the hairy warm-blooded viviparous four-footed mammals. But as there are both reptiles and mammalia which have only two legs, and as those of both classes which agree in having four legs differ essentially in the important characters on which classificatory distinctions are now founded, the term *quadruped* is no longer used in a strict zoological sense as indicative of a particular group of animals.

Quadruple (Lat. quadruplus). In Arithmetic, fourfold; the product of any magnitude or quantity multiplied by 4.

Quæstor (Lat.). In Roman Antiquities, the name of two distinct classes of public officers.

According to Varro, they were so called 'a quærendo, qui conquirerent publicas pecunias et maleficia.' The former, who collected the public revenues, were called *quæstores classici*; the latter, as public accusers or prosecutors in criminal cases, were known as *quæstores parricidii*. At first, like other offices, the quæstorship was confined to the patricians, and only after a severe struggle laid open to the plebeians; but beyond this broad fact, nothing can be determined with certainty from the traditions embodied in the writings of non-contemporary historians. According to some writers, two quæstors were for the first time appointed during the consulship of Valerius and Lucretius, soon after the expulsion of the kings, while others speak of the office as having existed under the kings. But all these writers agree in describing the office as one open only to patricians, and as continuing so until L. Papirius, B. C. 420, brought about a compromise on the arrangement that consular tribunes should be elected instead of consuls, and that four quæstors should be chosen promiscuously from patricians and plebeians, the singular result being that all the officers elected were patricians, and that no plebeian was elected quæstor for eleven years after this time. An altogether different account is given by Tacitus, who says that they were chosen first by the kings, then by the consuls, the election being afterwards transferred to the people, by whom the first military quæstors were appointed, the civil quæstorship being afterwards instituted for the business at Rome when the military quæstors were found unable to deal with it. 'It is impossible to reconcile any part of this account with the representation in Livy. Neither the transfer of the appointment from the consuls to the people, nor the time when the first quæstors were elected, nor the priority of the military to the urban prætors, agrees with Livy's statements. In this as in other cases, the accounts of the origin of an ancient institution, given by different writers, are wholly irreconcilable.' (Sir G. C. Lewis, *Credibility of Early Roman Hist.* ii. 286.)

Quagga. The name of a Solipedous quadruped, or species of *Equus*, allied to the zebra.

Quagmire. Boggy ground saturated with water to such a degree as to be more like mud than firm soil.

Quail (Ital. quaglia, Fr. caille). A genus of Gallinaceous birds (*Coturnix*, Cuv.), allied to the partridge, but of smaller size, with a more slender beak and shorter tail, and without red eyebrows or spurs.

Quakers or **Friends.** A religious sect, which arose in England about the middle of the seventeenth century, and spread, by the emigration of its members, who were exposed to many restrictions and to persecution in this country, over various parts of Europe and North America. Its founder was George Fox, who, being equally dissatisfied with the tenets of the established church and those of the Puritans, attached to himself various persons who agreed with his view of the internal operation of religion on men's hearts, conceiving it to supersede all ritual observances, and to be in no degree evidenced by them. The Quakers, therefore, reject all sacraments; nor do they appoint an order of ministers, but consider that the instruction of their congregations may be from time to time undertaken by any person of either sex who feels impelled thereto by a suggestion of the Spirit. Upon doctrinal points, however, they profess to maintain the opinions generally received by Christian churches and sects.

This society is distinguished in its intercourse with the world by great seriousness of deportment, uniform soberness in dress, and generally by a scrupulous avoidance of everything which can encourage vanity and frivolity. They are averse from all matters of ceremony, which they conceive to have their origin in flattery and deception. Their refusal to take judicial oaths used formerly to subject them to severe penalties. Up to the accession of James II. their history is a series of persecutions, either endured in common with other dissenters, or peculiar to themselves in consequence of their refusal to pay tithes and to take oaths. Under James, the severity of the penal laws was relaxed; William Penn, one of the earliest Quakers, the founder of Pennsylvania, having been one of that monarch's confidential advisers, or, as some say, tools, in that matter. But William III. was the first prince who enacted laws for their special relief. Under his reign their affirmation was received in lieu of oath in judicial proceedings; a privilege since extended by various Acts to Moravians, Separatists, and persons who have left those societies but retain conscientious scruples to taking an oath. (Fox's *Journal*; Barclay's *Apology*; and Sewell's *History of the Rise, &c. of the Quakers*, 1722.) The Quakers of the present day are thought to be a decreasing sect. In 1800 they possessed 413 meeting houses, while the number returned in 1851 was only 371. They are most numerous in Yorkshire, Lancashire, Durham, Cumberland, and Essex. Small communities are found in parts of France, Germany, Norway, the United States, and Australia. (*Religious Census* 1851.)

Quaking Bog. Peat bog in a growing state, and so saturated with water that a considerable extent of surface will quake or shake, when pressed on by the foot or any other body. Such bogs are unfit for any useful purpose till they are drained.

Quality (Lat. qualitas, from qualis, *of what sort*). In the philosophy of Kant, the *second* category (there being four in all), comprising the notions of existence or reality, nonexistence or negation, and limitation.

Quality. In Logic, a division of propositions, founded on their affirmative or negative character.

Quality. In Physics, some property or affection of bodies. Sensible qualities are those which immediately affect the senses; as figure, taste, &c.

Quantic (Lat. quantus, *how great*). In its widest sense this term denotes a rational and

integral algebraical function. As, however, all such functions may be supposed to have resulted from the substitution of unity in place of one of the variables of a homogeneous function, a quantic is usually understood to denote any rational integral homogeneous function. The term, which is both convenient and expressive, was introduced by Cayley, and is now in general use amongst English mathematicians. The especial terms *quadric, cubic, quartic, quintic,* &c. . . n^{ic} are used to denote quantics of the *second, third, fourth,* &c. . . n^{th} degrees in the variables, and as a further distinction, quantics are said to be *binary, ternary, quaternary,* &c. . . n-ary according as they contain *two, three, four* &c. . . or n variables. Thus a *ternary quadric* denotes a rational integral and homogeneous function of the fourth degree in three variables or facients. According to the ordinary notation of algebra, the most general form of such a function would be denoted by

$$ax^2 + by^2 + cz^2 + dyz + ezx + fxy,$$

and according to the notation of quantics by

$$(a, b, c, d, e, f, \overset{\leftarrow}{\between} x, y, z)^2,$$

or more simply by

$$(^*\between x, y, z)^2$$

when it is wished to indicate rather than to express the coefficients. The arrow-head in the above symbol denotes the *absence* of expressed *numerical* coefficients in the ordinary expression of the quantic. In operating upon quantics, however, it is usually more convenient to assume a different general form, and

$$(a, b, c, d, e, f \between x, y, z)^2$$

denotes that the several terms of the quadric are affected with the same numerical coefficients as are the like terms in the developement of $(x+y+z)^2$. [MULTINOMIAL THEOREM.] The trilinear equation of a curve, or the quadriplanar one of a surface being a quantic, the terms *quadric, cubic,* &c. . . . are also applied to curves and surfaces of the second, third &c. . . orders respectively. Prof. Cayley's original memoirs on Quantics will be found in the *Philosophical Transactions* for 1854 and subsequent years.

Quantity (Lat. quantitas). A property of anything capable of being increased or diminished. Quantity is distinguished into *continued* and *discrete.* It is continued when the parts are connected together, and is then called magnitude, which is the object of geometry. It is discrete when the parts have an unconnected and independent existence, forming multitude or number, which is the object of arithmetic. The quantity of matter in a body is termed its MASS; the quantity of motion it possesses its MOMENTUM.

QUANTITY. In Logic, the extent to which the predicate in a proposition is asserted of the subject. If it be asserted of the whole (all, none), the proposition is universal. If it be asserted of part only (some), the proposition is particular. A singular proposition is regarded as universal.

QUANTITY. In Prosody, the amount of time in a syllable. Syllables are either short or long; the former being the unit or smallest measure of time, the latter consisting of two times. This distinction is clearly marked in the ancient languages; in which some syllables are necessarily long or short by position, others by the nature of the vowels which they contain, and some common, or susceptible of being sounded as long or short, according to certain rules of elegance or convenience. The whole metrical system of the ancient languages is founded on quantity. In most modern languages there is, strictly speaking, no quantity, as distinct from emphasis, or accent; the long syllables being those which receive the arsis, the short those which receive the thesis. In the German language, however, critics have endeavoured to establish a conventional system of quantity, and thus to adapt that language to regular versification in the ancient Greek and Latin metres. [RHYTHM; METRE.]

Quaquaversal Dip (Lat. quaqua, *wheresoever,* and versus, *turned*). When deposits have been lifted up by elevatory force acting at a single point, they assume a dome-like form, and the beds dip in every direction from this central elevated point. Such dip is called *quaquaversal.* [DIP AND STRIKE.]

Quarantine. A period of time of variable length, during which a vessel from certain coasts or ports, said or supposed to be infected with certain diseases, is not allowed to communicate with the shore, except under particular restrictions. A ship in quarantine carries a yellow flag at the main; and when released from this condition, she is said to obtain *pratique.* The term is derived from the Ital. quaranto, *forty,* it being generally supposed that if no infectious disease break out within forty days or six weeks, no further danger is to be apprehended. It is believed that the Venetians were the first to adopt regulations for guarding against the introduction of infected persons into their ports; but there is now no civilised country in which it is not more or less practised. Of late years the rapidity of steam communication, the great improvement in the sanitary condition of the people, the progress of chemical science, which has led to the discovery of powerful disinfectants, and perhaps the scepticism with which many received opinions on the subject of infection have been encountered by some physiologists, have led to the gradual relaxation of quarantine laws; and now, although the power to impose it rests with the crown, quarantine is rarely demanded in British ports. (For full particulars on the history and policy of quarantine, see the *Com. Dict.*)

QUARANTINE. In Law, the forty days during which a widow is, by Magna Charta, entitled to reside in her husband's capital messuage after his death. During this time her dower shall be assigned. [DOWER.]

Quare Impedit (Lat.). In Law, the ordinary action to establish the right of a patron to present to an ecclesiastical benefice when

his title to do so is disputed. The action is brought in the Court of Common Pleas. The procedure relating to it has recently been simplified by stat. 23 & 24 Vict. c. 126.

Quarrel (Mod. Lat. quadrellus, Fr. carreau). The arrow or bolt for the crossbow in mediæval warfare. The word is derived from the four-sided pyramidal form of the head.

Quarrying (Fr. carrière). The process of removing valuable mineral produce from the earth when it can be got at without sinking pits or driving tunnels into the interior. It is generally the mode adopted for obtaining marble, building stone, road metal, slate, chalk, &c., but is occasionally adopted for metalliferous minerals and coal. Large quarries of ironstone are worked in the isle of Elba, near Malaga in Spain, and in many other places. Coal has often been quarried in England, and is generally so obtained from some of the thick beds in the centre of France. On the other hand, many valuable stones are obtained by tunnels. This is the case on a very large scale with the Bath and Caen stones.

The first operation in quarrying is to remove the head of rubbish and vegetable soil, and it is evident that for this, and for the placing of such waste material as may be produced in quarrying, either a large space is needed or these matters must be got rid of in some other way. Many quarries are opened on hill-sides and on cliffs near the sea, there being in either case conveniences for removal of waste.

In working a quarry extensively it is usual to work in several stages one above another. In this way many hundred men can be employed at once. For removing the stone, blasting is generally resorted to. This involves some danger, and shelter for the men during a blast is very desirable. Slate affords the largest and most valuable quarries in the world.

Quart (Lat. quartus, *fourth*). A measure of capacity, being the fourth part of a gallon. The word was also used during the middle ages to denote the fourth part of the tun, i.e. 63 gallons. [MEASURES.]

Quartan (Lat. quartana, sc. febris). A species of intermittent fever or ague. The interval between the attacks is only two whole days, nosologists having chosen to reckon the day of attack and the day of recurrence, so counting four days, and giving the name accordingly. [AGUE.]

Quartation. This term was formerly applied to the separation of silver from gold by means of nitric acid. To extract the whole of the silver from gold by the action of nitric acid, it is necessary that there should be at least three parts of silver to one of gold, otherwise the gold protects the silver from the action of the acid; so that, in thus separating these metals, it was customary where gold greatly predominated to add silver till it constituted at least three-fourths of the alloy. This separation of gold from silver is now effected by sulphuric acid.

Quarter (Lat. quartus). The fourth part of anything. As a term of weight, this word denotes the fourth of a hundredweight, or twenty-eight pounds.

QUARTER. As a dry measure, *quarter* is a term apparently of foreign origin, and probably Norman. It is uncertain whether it is the fourth part of some measure which has been long disused, or whether the word is connected with a division of land also known by the name. (Ducange.)

QUARTER. The after part of the ship's side, comprising about one-fifth of her total length. *On the quarter*, implies the bearing or position of an object seen between aft and abeam.

Quarter Days. The days usually regarded in England and most Continental countries (but not in Scotland) as beginning the four quarters of the year. They are: 1. Lady Day (March 25); 2. Midsummer Day (June 24); 3. Michaelmas Day (September 29); and 4. Christmas Day (December 25).

Quarter Deck. The portion of the uppermost deck of a ship between the main and mizen masts when there is a poop, but when there is no poop extending from the mainmast to the stern. This is the *parade* in men-of-war.

Quarter Round. In Architecture. [ECHINUS; OVOLO.]

Quarter Sessions of the Peace. In Law, a court held by two justices at least, one of whom must be of the quorum, quarterly, in every county. Its jurisdiction, originally confined to matters touching the breach of the peace only, has been extended by various statutes too numerous to be cited here. The criminal jurisdiction is principally defined by stat. 5 & 6 Vict. c. 38, and may be said to extend generally to the smaller misdemeanours and felonies, but with numerous exceptions. There is also an extensive jurisdiction in matters relating to the settlement and relief of the poor, highways, bastardy, &c., in most of which cases an appeal lies to the Court of Queen's Bench. [JUSTICES OF THE PEACE.] The administration of the county rates also belongs to the quarter sessions. Quarter sessions in boroughs, since the Municipal Corporation Act, are held by the recorders.

Quarter Sights. In Gunnery, sights on the sides of a smooth-bored gun, consisting of notches on the base ring, the lowest of which forms, with a notch on the side of the swell of the muzzle, a line parallel to the axis, the others forming lines inclined to the first at angles from fifteen minutes to three degrees.

Quarters. The stations of a ship's crew in time of action, to which they are summoned by beat of drum, or by the boatswain's pipe.

QUARTERS. In Military language, the room or rooms in barracks, or house, being government property, allotted to an officer for his accommodation.

Quarters and Quartering (Fr. quartiers). In Architecture, the upright posts in partitions to which the laths are nailed. Quarters are either single or double, the former being of sawn stuff four inches broad, and two and a

half or two inches in thickness; the latter being usually sawn to a scantling of four inches square. No quarters should ever be more than fourteen inches apart from out to out, even when the spaces between them are filled in with what is called *brick nogging*. Quartering is a term properly applied only to an assemblage of quarters, though it is not unfrequently used to denote the quarters themselves.

Quarter-master. In the Army, an officer whose business it is to look after the *quarters* of the soldiers, and attend to their clothing, rations, ammunition, &c. There is a quarter-master attached to every regiment of cavalry, battalion of infantry, or brigade of artillery.

QUARTER-MASTER. In the Navy, a petty officer, who, besides other duties of superintendence over the stowage of ballast, provisions, &c., attends to the steering of the ship.

Quarter-master-General. One of the chief staff officers of the army. His department is charged with all orders relating to the marching, embarking, disembarking, quartering, billeting, and cantoning of troops; encampments, and camp equipage. There are assistant and deputy-assistant quarter-master-generals of divisions and districts.

Quarter-staff. A weapon of defence; so called from the manner of using it, one hand being placed in the middle, and the other equally between the middle and end.

Quartering. In Heraldry, the division of a shield by two lines, fess-wise and pale-wise, meeting in the centre of the shield. In marshalling, whenever a husband can place his wife's arms on an escutcheon of pretence [ESCUTCHEON], the children may bear them quarterly with their own: whence arises the great variety of quarterings in the shields of some families.

Quartette or **Quartet** (Ital. quartetto). A piece of music arranged for four solo voices or instruments. Of the latter the most celebrated are arranged for two violins, a viola or tenor violin, and a violoncello; and many of the most distinguished composers, among whom we may mention Haydn, Mozart, Beethoven, Romberg, Spohr, Ries, Onslow, &c., have devoted their talents to this species of composition.

Quartic. In Algebra, a homogeneous function of the fourth degree in the variables or, as the latter are sometimes termed, facients. [QUANTIC.] Binary, ternary, and quaternary quartics have been most studied, in consequence of their connection, respectively, with the theories of equations, of curves, and of surfaces.

A *binary quartic*

$$(a, b, c, d, e)(x, y)^4,$$

put equal to zero, gives rise to a biquadratic equation in $\frac{x}{y}$. Its canonical form is

$$x^4 + 6mx^2y^2 + y^4,$$

and since the equation corresponding to the latter may be solved as a quadratic, the solution of a biquadratic equation obviously resolves itself into the reduction of the general quartic to its canonical form. This requires, as will be seen, the solution of a cubic. [BIQUADRATIC EQUATION.] The two fundamental invariants of the quartic are

$$S = ae - 4bd + 3c^2,$$

and

$$T = ace + 2bcd - ad^2 - eb^2 - c^3,$$

which latter is also the CATALECTICANT. These invariants, for the canonical form, reduce themselves to $1 + 3m^2$ and $m - m^3$ respectively. The coefficient m, therefore, is a root of the cubic

$$4m^3 - mS + T = 0.$$

Prof. Sylvester has shown (*Phil. Mag.* 1853) that every other invariant of a quartic can be expressed in terms of S and T; its discriminant, for instance, is $S^3 - 27T^2$. Having determined m from the foregoing cubic equation, the facients x and y of the canonical form are determined by considering the principal covariant of the quartic, which is its Hessian, H—another quartic easily obtained from the original. [HESSIAN.] For the canonical form the Hessian becomes

$$m(x^4 + y^4) + (1 - 3m^2)x^2y^2.$$

Hence the relation between the facients x, y, of the canonical form, and those of the original quartic U, may be deduced from the equations

$$x^4 + y^4 + 6mx^2y^2 = U,$$

$$m(x^4 + y^4) + (1 - 3m^2)x^2y^2 = H,$$

which latter gives readily

$$x^2y^2(1 - 9m^2) = H - mU,$$

and shows that

$$H - m_1U,\ H - m_2U,\ H - m_3U,$$

are each perfect squares, m_1, m_2, m_3, being the roots of the above cubic. But it may be shown further, that

$$(m_2 - m_3)\sqrt{H - m_1U} + (m_3 - m_1)\sqrt{H - m_2U} + (m_1 - m_2)\sqrt{H - m_3U}$$

is also a perfect square; and since it is manifestly reduced to zero by the hypothesis $U = 0$, its square root must be one of the four linear factors of U. This elegant solution of a biquadratic was first given by Prof. Cayley. The remaining important covariant of a quartic is the cubicovariant J of the first emanant; it is a sextic, which for the canonical form reduces to

$$(1 - 9m^2)xy(x^4 - y^4).$$

Further details on this subject will be found in Prof. Cayley's memoirs on Quantics in the *Phil. Trans.* 1855, and in Dr. Salmon's *Higher Algebra.*

Ternary Quartics equated to zero, represent *quartic curves* whose general properties have been but little investigated. Such curves might be classified according to the number of their double points or cusps, which can at most amount to three. [DOUBLE POINT.] The general curve, which has no such singularities, is of the 12th class, and the curve which has the

maximum number of cusps (three) is only of the 3rd class. Between these extremes may occur quartic curves of every other class. One interesting case is where the curve has a *triple point*, equivalent to three double points [MULTIPLE POINT]; its class is reduced to 6, 5, or 4, according as none, two, or all three of the tangents at the triple point coincide. The general quartic, of the 12th class, has 24 points of inflexion; the Hessian, which passes through them, being a curve of the 6th order. The 24 stationary tangents at these points of inflexion always touch a curve of the 4th class. The general quartic, too, has 28 double tangents, as was first shown, indirectly, by Plücker, and directly by Cayley. (Crelle's *Journal*, vol. xxxiv.) The equation of the curve of the 14th order which cuts the quartic in the 56 points of contact of its double tangents was given by Hesse (Crelle's *Journal*, vol. xli.) and Salmon (*Higher Plane Curves*). Through the four points of contact of any pair of double tangents, five conics can be drawn, each of which will pass through the four points of contact of another pair. In this manner 315 conics can be found, each of which will pass through the 8 points of contact of two pairs of double tangents. Salmon, in his *Higher Plane Curves*, has formed a scheme of them, and Steiner has also examined their relative positions and properties. (Crelle's *Journal*, vol. xlix.) The subject is, however, exceedingly complicated, and for further information the reader must be referred to the papers of Cayley, Hesse, Salmon, Jacobi, Steiner, &c., in the pages of Crelle's *Journal*, *Phil. Trans.*, and *Cambridge and Dublin Mathematical Journal*.

The best known quartic curves are the Cartesian and Cassinian ovals, the Limaçon of Pascal, the Cardioid, the Conchoid of Nicomedes, and the central pedals of Conics, which latter include the Lemniscata of Bernoulli. Short descriptions of these quartics will be found under their respective names.

With respect to *non-plane quartic* curves, or those which are cut by every plane in four, real or imaginary, points, the researches of Cayley, Salmon, Chasles, Steiner, and others, have made us familiar with many interesting properties. We can here merely notice their division into two families: *quadro-quadro quartics* and *ex-cubo quartics*, referring the reader for further information to the pages of Crelle's *Journal*, of the *Comptes Rendus*, and of Salmon's *Analytical Geometry of Three Dimensions*.

A *quadro-quadro quartic* constitutes the complete intersection of two quadric surfaces. Through such a curve, therefore, innumerable quadric surfaces can be drawn, amongst which will be four cones, and an infinity of hyperboloids of one sheet. No right line can meet such a curve in more than two points, so that the plane projection of the quartic can at most have double points (it will in general have two), and may possibly be a conic (doubled): in general, any plane cubic may be considered as the projection of a *quadro-quadro* quartic from a point on the curve. Further, such a quartic may always be regarded as the partial intersection of a cubic and a quadric surface which have in common a plane conic, and conversely two such surfaces always intersect in a *quadro-quadro* quartic curve.

There is, however, one interesting family of quartic curves, through which only one quadric surface, and that a ruled surface, can be drawn. These are called *ex-cubo quartics*. A quadric and a cubic surface which have in common two non-intersecting right lines, always intersect in such a curve. For every generator of the quadric which does not intersect the two common lines must necessarily meet the cubic, and therefore the quartic curve under consideration in *three* (real or imaginary) points. No second quadric, therefore, could be drawn through such a quartic curve; for not only it, but every other quartic which its existence implies, would have to cut all such generators in three points. An *ex-cubo* quartic meets one set of generators of the quadric surface on which it lies in three points, and those of the other set in one. Its projection on any plane, therefore, from a point on the curve, is always a cubic with a double point; its plane projection from any point in space is a quartic with three double points. Next to the non-plane cubic the *ex-cubo* quartic is the simplest of all curves of double curvature, and its points may be constructed linearly, as has been shown by Cremona (*Annali di Matematici*, t. iv. 1861).

Quartic surfaces have been but little investigated.

Quartile Aspect. In Astrology, this term denoted the aspect or appearance of two planets, whose positions are at a distance of 90° on the zodiac.

Quartine. The fourth envelope of the vegetable ovule, beginning to count from the outside.

Quartinvariant. [INVARIANT.]

Quarto. In Printing, a book printed in four leaves, or eight pages. It is abbreviated 4to.

Quartodecimans (Lat. quartus, and decimus, *tenth*). In Ecclesiastical History, a name applied to those who celebrated Easter on the fourteenth day of the paschal moon, instead of on the Sunday next following. This practice was maintained by the Eastern Christians, who appealed to the personal authority of St. John as a sanction for their observing the anniversary of the Jewish passover in the evening between the fourteenth and fifteenth of the month Nisan. But the Western with some of the Eastern Christians, on the ground that Christ was Himself the passover, broke their fast for the first time on the great festival of the resurrection on Easter Sunday. These appealed to the fourth gospel, which bears the name of St. John. In his great quarrel with the Roman bishop Victor, Polycrates, bishop of Ephesus (A.D. 190), grounded his retention of the Eastern usage on the un-

varying practice of Polycarp, Melito Philip, and St. John, while no direct reference is made to the fourth gospel, even by Apollinaris bishop of Hierapolis, a zealous opponent of the Eastern observance.

Quartz. A German term, now universally adopted in scientific language, and commonly applied to the purer varieties of silica, especially to Rock Crystal.

Quartzite or **Quartz Rock.** An aggregated rock consisting of quartz not absolutely crystalline. It sometimes appears in strata, and differs from sandstone in being more closely compacted and having a finer grain. It passes into sandstone on one hand and crystalline quartz on the other.

Quas. A fermented liquor used in Russia, and prepared from a mixture of meal and malt.

Quasi (Lat. *as it were*). In the language of Jurisprudence, this word, as a prefix, implies that the subject is something nearly related to, but not quite amounting to, that with which it is compared: thus, in Roman law, a *quasi-delict* and a *quasi-contract* are often spoken of; but it is essential to remember that as a *quasi-delict* is not a criminal offence, so a *quasi-contract* is no contract, express or implied, but only resembles one. 'The commonest sample is the relation subsisting between two persons, one of whom has paid money to the other through mistake.' Here, though morality raises a bond of duty in the receiver to return the money, there is no contract on his part to do so. (Maine's *Ancient Law*. ch. ix.)

Quasimodo. In the Roman Catholic Calendar, the first Sunday after Easter; so called because the *Introit* for that day begins with the words 'Quasi modo geniti infantes.' (1 Pet. ii. 1.) It is also called Dominica in albis, as being the day on which those who had been baptized on Easter Sunday deposited their white robes in the sacristy.

Quassia. The wood of the *Quassia amara*, a native of South America, and of *Picraena excelsa*, a tree found in some of the West Indian islands. It yields an intensely bitter infusion, which is used medicinally and is a good vehicle for metallic salts, many of which are decomposed by other bitter vegetable infusions. A strong infusion of quassia, sweetened with brown sugar, is an effective poison for flies.

Quassin. *Quassite*. The bitter colourless crystalline principle of quassia wood.

Quaternion (Lat. quaternio, *the number four*). Adopting, for conciseness, an expressive term employed by Sir William Rowan Hamilton, the inventor of the new science of Symbolical Geometry known as the *Calculus of Quaternions*, a quaternion may be defined as the *metrographic* relation which exists between any two right lines having definite lengths and directions in space. In what follows we purpose, solely, to convey a somewhat more accurate conception of a quaternion, and to explain briefly in what manner it depends, as its name implies, upon *four* irreducible geometrical elements.

The reader desirous of further information must be referred to Sir W. R. Hamilton's *Lectures on Quaternions*, Dublin 1853; to Dr. Salmon's *An. Geom. of Three Dimensions*; or to the recently published *Elements of Quaternions* by Sir W. R. Hamilton.

The operation of passing from any point O in space to any other point A is termed a *vector*, and denoted either by OA or a single symbol α, which must be regarded as involving the conceptions of length and direction, but not of position in space; so that two vectors OA and O′A′ will be equal if by simply moving the line OA parallel to itself, until O coincides with O′, its other extremity A falls upon A′. The addition of vectors is defined by the ordinary equations $OA + AC = OC$, which may be interpreted as indicating that the successive performance of the operations OA, OC is equivalent to the single operation OC. Thus the diagonal is the *geometrical sum* of the coinitial sides of a parallelogram or of a parallelopiped. The reverse operation to AB is denoted by $-AB$, and is clearly equivalent to BA, since by the above relation

$$AB + BA = AA = 0.$$

It is now clear that if i, j, k denote three fixed and mutually rectangular unit-vectors, any other vector ρ will be expressed by $ix + jy + kz$, where x, y, z are positive or negative numbers (*scalars*), expressing the ratios to unity of the ordinary coordinates of the extremity of a vector, equal to ρ, drawn from the coordinate origin. This being premised, we proceed next to the consideration of a *quaternion* or geometrical quotient $\frac{\beta}{\alpha}$, where β and α are any vectors. It is clear that OB and OA being any coinitial vectors equal to β and α, this quaternion may be represented by the *biradial* or unclosed triangle BOA; it may be also written thus $\frac{OB}{OA}$ and regarded as the operation necessary for changing OA into OB, so that

$$\left(\frac{OB}{OA}\right) OA = OB.$$

Now this operation may be resolved into, and perfectly defined by, two other *commutative* operations of *tension* and *version*; viz. *first* a stretching of OA until it attains the length of OB, and *secondly* a turning of the thus stretched line, from left to right, around a certain axis perpendicular to the plane of AOB, through the angle

$$\theta = A\hat{O}B \; (<\pi).$$

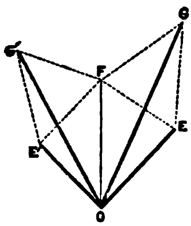
A quaternion is thus seen to be perfectly defined by four elements, viz. the ordinary *ratio* of OB to OA, the two angles which define the direction of the axis, and the angle θ.

To illustrate this still further, however, we remark that the representative biradial of a quaternion may have its sides lengthened or shortened as we please provided their ratio remains the same, may be transported into any parallel plane, and turned in any manner *in*

that plane. Again, if the multiplication of two coinitial quaternions be defined by the equation

$$\frac{OC}{OB}\cdot\frac{OB}{OA}=\frac{OC}{OA},$$

the products $\frac{\delta}{\gamma}\cdot\frac{\beta}{\alpha}$ and $\frac{\beta}{\alpha}\cdot\frac{\delta}{\gamma}$ of any two quaternions whatever may be thus exhibited.



Let the vectors α and β be parallel to the plane G′OEF, and γ and δ to GOE′F; and, having taken any point F in the intersection of these planes, let

$$\frac{OF}{OE}=\frac{OG'}{OF}=\frac{\beta}{\alpha},$$

and

$$\frac{OG}{OF}=\frac{OF}{OE'}=\frac{\delta}{\gamma},$$

then
$$\frac{\delta}{\gamma}\cdot\frac{\beta}{\alpha}=\frac{OG}{OF}\cdot\frac{OF}{OE}=\frac{OG}{OE}$$

and
$$\frac{\beta}{\alpha}\cdot\frac{\delta}{\gamma}=\frac{OG'}{OF}\cdot\frac{OF}{OE'}=\frac{OG'}{OE'}$$

These products, it will be seen, are not equal; for although the ordinary ratios OG : OE and OG′ : OE′ are equal, as well as the angles EOG and E′OG′, the planes of the respective biradials have not the same aspect. In the multiplication of quaternions, therefore, the order of the factors must be regarded. If the angles EOF = FOG′ and E′OF = FOG were all right angles, in other words if the factors $\frac{\beta}{\alpha}$, $\frac{\delta}{\gamma}$ were *rectangular quaternions*, then although the biradials EOG and E′OG′ would be in the same plane, the rotations would be of an opposite character; two such quaternions are termed *conjugate*. If the planes of the quaternions were also at right angles to each other, we should have

$$\frac{\beta}{\alpha}\cdot\frac{\delta}{\gamma}=-\frac{\delta}{\gamma}\cdot\frac{\beta}{\alpha}.$$

An ordinary *signless* number may clearly be represented by a quaternion, i.e. by the quotient of two like-directed vectors. Now since, by definition,

$$\frac{\gamma}{\alpha}=\frac{\gamma}{\beta}\cdot\frac{\beta}{\alpha},$$

we may, on supposing the perfectly arbitrary vector β to have the same length as α and the same direction as γ, or the same length as γ and the same direction as α, write

$$\frac{\gamma}{\alpha}=\mathrm{T}\left(\frac{\gamma}{\alpha}\right)\cdot\mathrm{U}\left(\frac{\gamma}{\alpha}\right)=\mathrm{U}\left(\frac{\gamma}{\alpha}\right)\cdot\mathrm{T}\left(\frac{\gamma}{\alpha}\right),$$

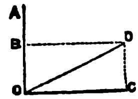
where the *tensor* T is represented by a pure number, and merely stretches, whilst the *versor* U turns without alteration of length. This illustrates the resolution of a quaternion into the product of its tensor and versor.

Another method of resolving a quaternion results from the following definition of the addition of quaternions:

$$\frac{OB}{OA}+\frac{OC}{OA}=\frac{OB+OC}{OA}=\frac{OD}{OA},$$

where OD is the diagonal of the parallelogram whose sides are OB and OC. As a particular case of the double application of this definition it will readily be seen that any rectangular quaternion whatever may be resolved into a sum of three rectangular quaternions in the fixed planes of the mutually rectangular vectors i, j, k.

Again, any quaternion $=\frac{OD}{OA}$ may by projecting OD upon the line of OA and upon a line perpendicular thereto, be expressed in the form



$$q=\mathrm{S}(q)+\mathrm{V}(q),$$

where the quaternion $\mathrm{S}(q)=\frac{OB}{OA}$ resolves itself into a *positive* or *negative number* or fraction, and is called the *scalar* of q, whilst the quaternion $\mathrm{V}(q)=\frac{OC}{OA}$ is rectangular and receives the name of the *vector* of q because, as will be presently apparent, a rectangular quaternion may always be represented by a vector, considered as an axis of right-handed rotation, whose length is equal to as many linear units as the tensor of the quaternion contains numerical ones.

In fact, if I, J, K, represent rectangular versors (quaternions with unit tensors) whose planes are respectively perpendicular to the fixed rectangular unit-vectors i, j, k, it will be readily seen that from the foregoing principles

$$\mathrm{IJ}=-\mathrm{JI}=\mathrm{K},\ \mathrm{JK}=-\mathrm{KJ}=\mathrm{I},\ \mathrm{KI}=-\mathrm{IK}=\mathrm{J},$$

each of which equations expresses the equivalence of certain operations. It is also evident, by operating upon the *subjects* i, j, k, that

$$\mathrm{I}j=-\mathrm{J}i=k,\ \mathrm{J}k=-\mathrm{K}j=i,\ \mathrm{K}i=-\mathrm{I}k=j.$$

These equations have precisely the same forms as the foregoing ones, so that the distinction between the rectangular versors I, J, K, and the corresponding unit-vectors i, j, k, need no longer be retained. When we please, therefore, the symbols i, j, k, may be regarded as operative ones which combine according to peculiar laws, all of which are expressed by the equations

$$i^2=j^2=k^2=ijk=-1.$$

Now, since every rectangular quaternion may be resolved into a sum of three rectangular quaternions in the coordinate planes, the quaternion $\mathrm{V}(q)$ above considered may be expressed in the form

$$xi+yj+zk,$$

where x, y, z, are positive or negative numbers; so that, denoting by w the positive or negative number $\mathrm{S}(q)$, we have the following irreducible expression for a quaternion

$$q=w+xi+yj+zk.$$

We cannot here enter into the applications of Quaternions to Geometry and Mechanics, and must close this very imperfect sketch of the elements of the calculus with the remark that, in it, $\sqrt{-1}$ is the general symbol of rotation through a right angle, and that the decomposition of a quaternion into its scalar and vector parts at once leads to an expression of the form

$$q = m\,(\cos\theta + \sqrt{-1}\,\sin\theta),$$

where m is a pure number, and θ the angle of the quaternion; whence it will be readily understood that a quaternion may be also represented as a *power of a vector*, considered as a rectangular versor. As in ordinary algebra, however, this symbol $\sqrt{-1}$ sometimes denotes, in the Calculus of Quaternions, an impossible operation. It then gives rise to what are termed *biquaternions*, for a definition of which, however, the reader must be referred to the writings of their eminent inventor.

Quatrain (Ital. quattrino). In Poetry, a piece consisting of four verses, the rhymes being usually alternate, but sometimes, especially in French poetry, intermixed, the first and fourth, second and third, rhyming together.

Quatrefoil (Lat. quatuor, *four*, and folium, *a leaf*). In Heraldry and in Mediæval Sculpture, a flower of four leaves (quatre feuilles).

Quattrocentismo (Ital. quattro cento). A term expressing the peculiar or characteristic taste or so-called *purism* in art, prevailing in Italy in the fifteenth century. Hard and rigid in its manner, positive in its colouring, but predominating in sentiment; yet æsthetically very imperfect, it is the triumph of the Cinquecento to have supplied the æsthetic qualities wanting in the art of this period, and to have reformed its technical deficiencies, the sensuous being made coordinate with the sentimental. [CINQUECENTO.]

Quaver. In Music, a character, ♪, whose measure is equal to half a crotchet, or one-eighth of a semibreve.

Quay (Fr. quai, Dutch kaai). An artificial landing place, to enable ships which could not otherwise approach the shore to take in or disembark their cargoes without the intervention of small boats.

Quay Wall. A wall forming the support of ground left at a higher level than that of the roadway, or waterway, of the surrounding surface; thus the walls of a platform or of a dock, or pier, are said to be the *quay walls*, irrespective of the nature of the element whose force they have to resist. The thickness of quay walls, however, depends greatly upon this condition, which will be found discussed under RETAINING WALL. It may suffice here to mention that in the case of walls intended to protect the earthwork left behind a quay wall erected in dry ground, a thickness equal to one-third of the height would, on the average, be sufficient; but that, in the case of earthwork exposed to alternations of moisture and dryness, as in docks or harbours, the thickness to be given to the quay walls should, on the average, be at least one-half the height.

Queen (A.-Sax. cwen, Gr. γυνή; for the history of the root, see LANGUAGE). 1. A female sovereign; entitled *queen regnant*, or *queen regent*. She has, in Great Britain, the same power, prerogatives, &c., as a king, which is expressly declared by stat. 1 Mar. I. st. 3. c. i. In France, where females do not succeed to the throne, the title *queen regent* has been given to the mothers of kings holding sovereign authority, or a portion of it, during the minority of their sons; as Catherine de Médicis in the reign of Francis II.; Mary de Médicis, in that of Louis XIII.

2. *Queen Consort*. The wife of a king. Her rights and dignities (in England, as well as most other countries) appear to be similar in many respects to those of the 'Augusta,' or Piissima regina conjux divi imperatoris, in imperial Rome. The English queen, like the Roman empress, is capable of receiving a grant from her husband, or making one to him; therein differing from all other wives. She can also purchase and convey land, &c., without his concurrence; and sue and be sued alone: in short, she is looked upon in all legal proceedings as a feme sole. But, except where she enjoys specific exemptions, she is only on a footing with other subjects; and this also is according to the Roman maxim, 'Augusta legibus soluta non est.' By the Statute of Treasons, 25 Edw. III., to compass or imagine the death of the king's *companion*, and also to violate and defile her, is treason. The queen, if accused of treason herself, is tried by the peers of parliament; as Anne Boleyn in 28 Hen. VIII. The consort of George IV. was proceeded against by the method of a bill of pains and penalties. *Queen-gold* was a duty amounting to one full tenth of the value of fines, &c. on grants by the crown, anciently due to the queen; which Charles I. purchased of his consort Henrietta, in 1635, for 10,000*l*., but which was not revived after the Restoration. The queen consort has a separate household, consisting of six ladies of the bed-chamber, a chamberlain, vice-chamberlain, mistress of the robes, master of the horse, and three equerries, attorney and solicitor general, &c.

3. *Queen Dowager*. The widow of a deceased king. She continues to enjoy most of the privileges which belonged to her as queen consort. Nor did she, in ancient times, lose her dignity on remarriage; for Catherine, queen dowager of Henry V., after she had married Owen Tudor, maintained an action by the name of Catherine queen of England. But it is held that no man can marry a queen dowager without special license from the king, on pain of forfeiture of lands and goods, according to an Act of 6 Hen. VI., which, however, is not printed among the statutes. The revenue of a queen dowager is settled by statute. By 1 & 2 Wm. IV. c. 11, that king was empowered to settle

100,000*l.* per annum on his queen, to commence at his decease.

4. *Queen Mother.* A queen dowager who is also mother of the reigning sovereign.

Queen Anne's Bounty. [BOUNTY, QUEEN ANNE'S.]

Queen Post. In Architecture, an upright post in a roof for suspending the beam when the principal rafters do not meet in the head of the king post. A queen-post roof is employed whenever the span of the assemblage is above forty feet; it makes, in fact, an arch of the timber. [ROOF.]

Queen's Advocate. [KING'S ADVOCATE.]

Queen's Bench. [KING'S BENCH.]

Queen's Counsel. It has been customary for a long period to appoint the leading members of the bar to be the standing counsel of the crown. This practice appears to have originated in the reign of Charles II., and has been gradually extended until the position of a queen's counsel has come to be regarded as a professional rank which any barrister of a certain eminence may claim almost as of right. The functions of queen's counsel as representing the crown by virtue of their office are now merely honorary, though they formerly received a small salary by way of retainer. They receive the usual fees if retained on behalf of the crown on any particular occasion. They cannot be employed in any cause against the crown without a special license, which is never refused, but which involves an expense of about 9*l.* on each occasion. As the crown is the nominal prosecutor in criminal proceedings, no queen's counsel can defend a prisoner without a license, a circumstance which has incidentally a considerable effect in preventing the leading members of the bar from practising in the criminal courts. Queen's counsel have a right of precedence and pre-audience over the other members of the bar (which constitutes the chief advantage of the appointment), and by the etiquette of the profession they are forbidden to conduct causes, or to prepare pleadings or other legal instruments without the assistance of a junior counsel. Their professional robes are of silk instead of stuff (whence the term *silk* is often used to denote their rank). They are usually elected to be benchers of their respective Inns of Court. [BENCHERS.]

Queen's Metal. An alloy intermediate between Britannia metal and pewter, used for the manufacture of common spoons and teapots. It consists of nine parts of tin, one of lead, one of antimony, and one of bismuth.

Queen's Regulations. The regulations and orders issued by the queen to the army (through the commander-in-chief, as distinguished from those issued through the Secretary of State for War, which are War Office regulations). They regulate the whole military system, except in matters affecting finance. They interpret the Mutiny Act and Articles of War as regards military discipline, and furnish the rules for the interior economy of the service. Every officer is required to possess a copy, and to make himself perfectly acquainted with them.

Quellerz. A German term signifying *brook iron-ore*, a synonym of Limonite or Bog Iron-ore.

Quercitannic Acid. The astringent principle of oak bark. It differs from the tannic acid of oak galls.

Quercite (Lat. quercus, *an oak*). A crystalline saccharine matter contained in acorns.

Quercitrin. *Quercitric acid.* The colouring matter of quercitron bark. It is a crystalline, yellow, bitter substance.

Quercitron Bark or **Quercitron Tinctoria.** The bark of the *Quercus nigra.* This valuable dye stuff is used in the production of some of the most durable yellows. It contains a yellow crystallisable principle, *Quercitrin*, which is sparingly soluble in water, but is readily solved in weak alkalies. A decoction of this bark, deprived of its tannic acid by a little gelatine, produces a good yellow upon fabrics mordanted with alumina, or various shades of olive, with iron mordants. It is much used in calico-printing.

Quercus (Lat.). This is the most important genus of trees found in the cold countries of the world, on account of its producing the various kinds of timber called OAK. The species are not, however, confined to Europe, or similar latitudes, but occur abundantly in the equinoctial parts of Asia and America. It is usually recognised by the cup in which the acorn is seated; but in some tropical species the acorn is so small as to be buried in the cup, when the fruit nearly resembles that of the chestnut (*Castanea*). The valuable Oak of Great Britain is obtained from two native trees: the one *Q. pedunculata*, the long-stalked or white oak; the other *Q. sessiliflora*, the sessile-fruited or red oak. Oak timber is affected very much by soil and climate; and hence we have oak of bad quality from both our native species. What is called wainscot oak is probably the timber of *Q. sessiliflora*, grown rapidly in the dense forests of Hungary; by some persons, however, it is supposed to be furnished by an Oriental species called *Q. Cerris*, or the mossy-cupped. The *Æsculus* of Virgil, the acorns of which were eatable, appears to have been a sweet-fruited variety of *Q. sessiliflora.* Besides those already mentioned, the *Quercus Ilex*, or European oak, the *Q. Suber*, or cork-tree, whose bark is in such extensive use, and the *Q. Ballota*, or Spanish Ilex, whose acorns are sweet and eatable, are the more important species. Those from North America, although fine trees, are inferior to the oaks of England as regards their timber, and require hotter summers than we have in these islands. Oak galls are produced upon *Q. infectoria*, in the Levant, by the puncture of a cynips. The species of *Quercus* are excessively confused by botanists; but a full popular account of them will be found in Loudon's *Arboretum Britannicum*, and a scientific summary in the sixteenth volume of De Candolle's *Prodromus.* For a few popular details, see OAK.

Question (Lat. quæstio). The application of TORTURE to prisoners under criminal accusation, according to the law of France before the Revolution. The question was of two kinds: one, where strong evidence, but insufficient of itself to justify a condemnation to death, existed against a prisoner on a capital charge; he might then be subjected to torture to produce confession. This was termed the *question préparatoire*. It was abolished by an ordonnance of Louis XVI. in 1780. The other, termed *question préalable or définitive*, was applied to the prisoner when convicted of a capital offence, in order to make him discover supposed accomplices. It was abolished by the National Assembly. The preparatory question was also of two sorts: one, *avec réserve de preuves*, in which case, if the criminal did not confess under the torture, the other evidence was considered as still subsisting against him, so as to justify his condemnation to some lighter punishment; the other, *sans réserve de preuves*, in which case, if he persisted in his denial, he was acquitted altogether. It was at the option of the judges, according to their opinion of the amount of evidence, to decide to which of these questions the accused should be subjected. The modes of torture applied varied in France, being fixed by the several parliaments within their separate jurisdictions. (See a very curious dissertation on this horrible subject by M. Berriat Saint-Prix, *Des Tribunaux et de la Procédure du Grand Criminel au* 18° *Siècle*, 1859.) Those in common use at Paris were, the question by water, which consisted in stretching the limbs of the sufferer on a board by means of screws, and forcing him to swallow large quantities of water; and the boots, in which his legs were enclosed in wooden cases, the whole tightly compressed with ropes, and wedges driven with a mallet between the two cases. The question varied in degree, being *ordinary* or *extraordinary*, at the discretion of the judges. Children and adolescents, old men, and women with child, were excepted from torture by the French law. And, by an ordonnance of 1670, the second application of the question was forbidden in all cases. [RACK; TORTURE.]

Question, Previous. [PREVIOUS QUESTION.]

Questmen (Lat. quæstus, *a seeking*). Parochial officers sometimes appointed in large parishes to assist the churchwardens in enquiring into abuses, making presentments, &c.

Qui pro Quo or **Quid pro Quo** (Lat.). A conventional term borrowed from the French, who apply it to an error committed by mistaking one thing or person for another. In England it is used also in the sense of an equivalent.

Qui Tam (Lat. *who as well*). In Law, a penal action, in which half the penalty is given to the crown and the rest to the informer. The plaintiff, while Latin forms were in use, described himself as A. B. 'qui tam pro domino rege quam pro se ipso'—who sues as well for the king as himself.

Quia Emptores (Lat.). In English Law, the designation (from its first words) of the statute 18 Edward I. (A. D. 1290) which prevented subinfeudation. [FEUDAL SYSTEM.]

Quick Match. [MATCH.]

Quicklime. [LIME.]

Quicksilver. [MERCURY.]

Quietism. A name generally applied to the opinions of enthusiasts, who conceive the great object of religion to be the absorption of all human sentiments and passions into devout contemplation and love of God. This idea has found its admirers in all ages. A sect called by this name [HESYCHASTS] existed among the religious of Mount Athos; and in the seventeenth century it was given in France to a class of devout persons with a tendency towards a higher spiritual devotion. A Spanish priest, Molinos, published at Rome a work entitled *The Spiritual Guide* (1675), of which the ardent language attracted a multitude of partisans. Its leading feature was the description of the happiness of a soul reposing in perfect *quiet* on God, so as to become conscious of His presence only, and untroubled by external things. He even advanced so far as to maintain that the soul in its highest state is removed even beyond the contemplation of God himself, and is solely occupied in the passive reception of divine influences. The work of Molinos was afterwards condemned on the application of the Jesuits. Akin to the ideas of Molinos seem to have been those of the French Quietists, of whom Madame Guyon and Archbishop Fénelon are the most celebrated. The former was at one time treated as insane; at another, she was admitted to the intimacy of Madame de Maintenon, and rose high in court favour. Fénelon praised her in his treatise *Sur la Vie Intérieure* (1691). The writings of the latter upon this subject were finally condemned by Innocent XII.; and the example of the archbishop in submitting to the decision has been dwelt on by pious writers as a signal triumph of a religious mind. The dissolute conduct of some hypocritical priests, under the pretence of inculcating the tenets and practice of Quietism, brought it eventually into disrepute more than the repeated condemnations of the head of the Roman Catholic church.

Quilted Armour. Armour formed of soft material padded, and stitched at regular intervals, so as to keep the padding in its place. This armour is also called *pourpointed*, and was much worn in the middle ages.

Quincite. A hydrated silicate of magnesia and protoxide of iron, of a carmine-red colour, found disseminated in a fresh-water limestone, near Quincey, in the Département du Cher.

Quincunx. The Latin term properly for that disposition of five objects in which they are made to occupy the four corners and point of intersection of the diagonals of a square; but the word is extended to any number of things so arranged in lines that the members of each succeeding line stand behind the spaces between those of the preceding one. Troops

were frequently drawn up in this order, which was also a favourite arrangement for plantations of vines.

Quindecagon. In Geometry, a plane figure bounded by fifteen sides. The regular quindecagon is inscribable in a circle by elementary geometry. (*Euclid*, book iv.)

Quindecemviri. Roman magistrates, whose duty it was to take care of and to consult the Sibylline books.

Quinia or **Quinine.** An alkaline base obtained chiefly from yellow bark, *Cinchona Calisaya*, and other species. This substance, combined with sulphuric acid, forms the *sulphate of quinine*, now extensively used as a medicine, and as a substitute for the various forms of Peruvian bark. To obtain quinine, bruised yellow bark is boiled in repeated portions of water, acidulated by sulphuric acid, till all its soluble matters are extracted; a little excess of quicklime is then added to the strained decoction, and the precipitate which is formed is collected, washed, and carefully dried; it is then digested in alcohol, which takes up the quinine, and from which the latter may be obtained in the form of a yellowish substance by careful evaporation. It is dissolved in dilute sulphuric acid, and the sulphate of quinine crystallises from its concentrated solution in fine silky prisms, which effloresce on exposure to air. Sulphate of quinine is not easily soluble in water, and is intensely bitter. It is administered as a tonic and febrifuge in doses of from one to five or six grains.

The composition of quinine, in its anhydrous state, is represented by the formula $C_{40}H_{24}O_4N_2$, and the crystallised sulphate, as sold for medical use, is a compound of one atom of sulphuric acid, one of quinine, and fourteen of water. Its high price renders it liable to various adulterations. Quinine appears to be associated in the barks which afford it with some other analogous alkaloid, and the mixture is called *quinoidine*, and is said to contain two bases isomeric with quinine which have been termed *quinidine* and *quinicine*.

Quinicine. An alkaloid much resembling quinine and quinidine, from either of which it may be prepared by applying a temperature below their fusing point for a few hours.

Quinidine. One of the cinchona alkaloids. It is an isomer of quinine, which it much resembles; but it more readily crystallises, a much larger quantity of it is required to be taken into the system before an effect is produced equal to that obtained by a given amount of quinine, and finally its solutions have an opposite action on a ray of polarised light. Under the names of *quinidine* and *quinoidine*, various substances are sometimes sold for medical use, as comparatively cheap substitutes for sulphate of quinine, but on account of their indefinite composition they cannot be relied on.

Quinoidine. [QUINIDINE.]

Quinquagesima Sunday. In the Calendar, the seventh Sunday before Easter, and consequently *about* the fiftieth day before that festival; whence the origin of the term, from Lat. quinquagesimus, *fiftieth*.

Quinquatrus. In Roman Antiquities, the feast of Minerva, which began on March 19, and lasted five days.

Quinquennalia or **Ludi Quinquennales.** In Classical Antiquity, public games celebrated every five years. Tacitus (*Ann.* xiv. 20) says that they were introduced at Rome by Nero.

Quinquereme (Lat. quinqueremis, Gr. πεντήρης). The name of a class of Roman war ships rowed by five banks of oars. The introduction both of quadriremes and quinqueremes is attributed to the Syracusan tyrant Dionysius the Elder; while the younger Dionysius is said to have possessed hexeres, or ships with six sets of rowers. Polybius says that the first Punic war was carried on chiefly with quinqueremes. At Athens vessels larger than triremes were not introduced till about the time of Alexander the Great; and we first hear of a quinquereme in a document of B.C. 325. It is a matter of dispute how the banks of oars were disposed: some maintaining that they were above each other, others that such an arrangement must involve an impossible length of oar for the upper bank. Yet in works of art the ranks of oars appear one above another, although not perpendicularly; and thus more room was furnished for the various classes of rowers. In the ships ranging from the moneris (or ship with one bank of oars on each side) up to the quinquereme, each oar is said to have been managed by one man; but it is obviously impossible that one man could manage the long oars of a τεσσαρακοντήρης, thirty-eight cubits in length. For further details see Smith's *Dictionary of Greek and Roman Antiquities*, art 'Navis.' [TRIREME; GALLEY.]

Quinquina. Peruvian bark. The bark of various species of CINCHONA.

Quinsey (Ital. squinanzia, Gr. κυνάγχη). Inflammation of the tonsils. This is common inflammatory sore-throat: it is not infectious. It begins with pain on one side of the throat, and swelling of the tonsil, or of both tonsils at the same time, attended by febrile symptoms, which sometimes run high, especially as the tumefaction advances; there is great restlessness and anxiety, and often the utmost difficulty of swallowing even liquids, and of breathing. The disease has proved fatal by producing suffocation, but it generally terminates in resolution or suppuration: in the latter case the abscess breaks, a good deal of pus is discharged, and the patient is at once relieved of all his urgent symptoms.

Quintain (Fr. quintaine). An ancient pastime, in which a post was erected, with a crosspiece, turning upon a pivot on the top of it, to one end of which a sand-bag was suspended, and a board fixed at the other. The play consisted in riding or tilting against the board with a lance, and passing without being struck behind by the sand-bag.

Quintal. An old denomination of weight, being the same with the *hundred* weight, or equal to 112 pounds.

Quintessence (Lat. quinta essentia). A term applied by the older chemists to alcoholic tinctures or essences, made by digestion at common temperatures or in the sun's heat. In Alchemy it denoted the fifth or highest essence of power in a natural body.

Quintic. In the Higher Algebra, this term denotes a homogeneous function of the fifth order in the variables. [QUANTIC.] The theory of binary quintics has been most studied on account of its connection with algebraical equations of the fifth degree, the most general form of which is

$$x^5 + ax^4 + bx^3 + cx^2 + dx + e = 0.$$

Various attempts have been made by mathematicians to effect a finite algebraic solution of the quintic equation, i.e. to express a root of it by means of finite combinations of radicals and rational functions, as can be done for quadratic, cubic, and biquadratic equations. In particular cases such solutions have been discovered. Thus, De Moivre found that when the quintic takes the form

$$x^5 - 5bx^3 + 5b^2x - 2e = 0,$$

one of its roots is

$$\sqrt[5]{e + \sqrt{e^2 - b^5}} + \sqrt[5]{e - \sqrt{e^2 - b^5}};$$

and Euler found that when the quintic takes the form

$$x^5 + 5cx^3 + 5dx - \left(\frac{c^5}{d} - \frac{d^5}{c}\right) = 0,$$

one of its roots is

$$\sqrt[5]{\frac{c^3}{d}} - \sqrt[5]{\frac{d^3}{c}}.$$

These and other cases have been shown by Harley to be included in a large class of solvable forms. (*Manchester Memoirs*, vol. xv. second series, pp. 172–219.)

But all the attempts of mathematicians to discover a finite algebraical solution of the general quintic have hitherto failed. Abel, indeed (*Œuvres complètes*, Christiana 1839), has demonstrated that it is impossible, except in particular cases, to effect a finite algebraic solution of any equation of a higher degree than the fourth. His argument has been reproduced and modified by Sir W. R. Hamilton. (*Trans. Royal Irish Acad.* vol. xviii.; Abstract of Hamilton's Exposition by Cockle, *Quart. Journ. of Math.* vol. v.) A shorter and more simple demonstration of Abel's theorem has been given by Wantzel, and reproduced in Serret's excellent *Cours d'Algèbre Supérieure.*

Another important discovery which has been recently made in the theory of quintic equations is that the general quintic equation can be deprived of any three of its four middle terms by the aid of equations of inferior degrees, and so reduced to one of the following four trinomial forms:

$$x^5 + dx + e = 0$$
$$x^5 + cx^2 + e = 0$$
$$x^5 + ax^4 + e = 0$$
$$x^5 + bx^3 + e = 0.$$

In any one of these four forms we may make either the last coefficient e; or the intermediate coefficient a or b or c or d equal to unity or to any other assumed number except zero; so that the general quintic equation may, by the aid of lower equations, be reduced to a trinomial form involving only a *single variable parameter.* (See Jerrard's *Essay on the Resolution of Equations*, London 1859; also an historical paper by Harley in the *Quart. Journ. of Math.* vol. vi. 1863.)

Availing himself of this reduction of the general quintic to a trinomial form, involving only one parameter, M. Hermite, in his *Essai sur la Théorie des Equations modulaires et la Résolution de l'Equation du Cinquième Degré* (Paris 1859), has succeeded in expressing the roots of the quintic in terms of elliptic functions, and M. Kronecker, in Crelle's *Journal*, has shown that the same thing can be done for the equation in its complete form.

Attacking the problem from a different point, Harley, in vol. v. of the *Quart. Journ. of Math.*, has calculated a certain linear differential equation of the fourth order and remarkably simple in form, whose solution is shown to embrace the solution of the general quintic equation. [DIFFERENTIAL RESOLVENT.]

Quintile. In Astronomy, an aspect of two planets distant from each other the fifth of the zodiac, or 72°.

Quintine (Lat. quintus). In Botany, a name given to the fifth or innermost envelope of the vegetable ovule, the most external being the first or primine.

Quintuple. In Music, a species of time, now seldom used, containing five crotchets in a bar.

Quinzaine. In Chronology, the fourteenth day after a feast day, or the fifteenth if the day of the feast be included. But a different rule seems to have prevailed on the Continent. (Sir H. Nicolas, *Chronology of History*, p. 105.)

Quire. In Printing, a bundle of paper consisting of twenty-four sheets. A quire of newspapers consists of twenty-five sheets.

Quirinus. According to Dionysius of Halicarnassus, this is a Sabine word, derived, perhaps, from quiris or curis, *a spear*, with which some have connected the word curia, *a senate house.* Under this name ROMULUS was worshipped by the Romans after his deification.

Quirites. In Roman Antiquities, this name occurs in the expression *Populus Romanus Quirites.* By some it has been supposed that this phrase refers to a coalition of two tribes, the Romans and the Quirites, the latter belonging, perhaps, to a town called Cures or Quirium. But in the absence of all historical evidence, these suppositions can neither be proved nor refuted. According to Bekker, the name Roman denoted the people in its rela-

tion to foreign nations, while by Quirites were signified the citizens as individuals and in their social relations. Thus a man who claimed anything as exclusively his own, was said to claim it *ex jure Quiritium*.

Quirk. In Architecture, a piece of ground cut off from a square plot.

Quirked Moulding. In Architecture, a moulding in which the convexity is sudden, being in the form of a conic section.

Quit Rent (Lat. quietus reditus). In Law, a small rent payable by tenants of manors, so called because thereby the tenant is quit and free of other services. [Rent.]

Quiver (perhaps another form of the word *cover*). The receptacle for arrows of the long-bow, worn by the archer.

Quo Warranto. In Law, a writ, filed in the Court of Queen's Bench by the Attorney-General, or an individual in his name, calling upon the person informed against to show by what title he holds any office, franchise, or liberty. As the proceedings on a writ of quo warranto presented many difficulties, the writ has been superseded in modern times by what is termed an information in the nature of a quo warranto. [Corporations, Municipal.]

Quodlibet (Lat. *what you please*). In the language of the schoolmen, questions on general subjects within the range of their enquiries were termed *questiones quodlibeticæ*, or miscellaneous. What is termed in Music a *pot-pourri* was also called in Germany a *quodlibet*.

Quoin (Fr. coin, Gr. γωνία). In Architecture, the corner, or the internal and external angle of a building, or of any part of a building. It is generally applied to the stones that form the angles. These are spoken of as the quoin stones, to distinguish them from the rest of the ashlar.

Quoin. In Artillery, a wedge of wood put below the breech of a cannon, for the purpose of adjusting its elevation.

Quoin. On Shipboard, a wedge used in stowing casks, to prevent motion.

Quorum. A term derived from the words used in the Latin form of the commission issued to justices of the peace; in which the expression occurred, 'quorum unum A B esse volumus'—'of whom we will that A B be one;' thus rendering it necessary that certain individuals (said to be of the quorum) should be present at the transaction of business. Hence, when in an assembly, committees, &c. it is necessary that a certain number should be present to give validity to its acts, that number is generally said to constitute a quorum.

Quota (Lat. quotus, *of what number*). That part which each member of a society has to contribute or receive in making up or dividing a certain sum.

Quotation Marks. In Printing, two inverted commas placed at the beginning, and two commas in their direct position (or two apostrophes), at the end of a sentence quoted or transcribed from an author in his own words. They are called *guillemets*, from their inventor Guillemet, and by the Germans *gänse-augen*, or geese-eyes.

Quotidian (Lat. quotidianus). That form of ague which returns daily. [Ague.]

Quotient (Lat. quotiens, *how often*). In Arithmetic, the result of the operation of division; it may be either a concrete or an abstract number. When a magnitude of any kind is proposed to be divided into any number of parts, and the divisor is consequently an abstract number, the quotient is of the same kind with the dividend or quantity proposed to be divided; but when the dividend and divisor are both things of the same denomination, or both magnitudes of any kind, the quotient is an abstract number, and is the ratio of the one magnitude to the other.

R

R. One of the letters belonging to the series called *liquids* or *semivowels*. At the beginning of English words derived from the Greek through the medium of the Latin, *r* is usually followed by *h*, to represent the force of ῥ, as in *rhetoric*, *rhapsody*, as also when it occurs in the middle of an English word derived from a Greek compound, as in *diarrhœa*, from διά and ῥέω. This letter is susceptible of numerous interchanges, more especially in Latin. As an abbreviation, R. among ourselves stands for *rex* or *regina*; R. P. for *respublica*, &c. In medical prescriptions, R. stands for *recipe* or *take*.

Rabbet of the Keel (Fr. raboter, *to plane*). In Wooden Shipbuilding, an angular groove running on each side of the keel from end to end, and serving to receive the inner edge of the garboard strakes or lowest planks of the ship's bottom. In merchant vessels the rabbet is usually formed along the top edge of the keel. In the British Navy, on the other hand, its position is nearly half-way down the keel, the keel itself being mortised into the floors down to the top of the rabbet. This latter formation is considered to impart much greater strength, as it admits of thicker strakes, and from the less depth of keel left exposed below the rabbet diminishes the disruptive force brought to bear on the vessel's bottom in the event of her taking the ground. Similar rabbets on the stem and sternpost receive the ends of the several planks of the sides.

Rabbi. A Hebrew term for *doctor* or *teacher*; the termination being properly the first pronoun possessive. This word, which is frequently found in the New Testament, is in use at the present day, the rabbis being the expounders of the law, and more particularly of the TALMUD or commentaries of later doctors.

Rabbinism. A term under which is commonly designated the body of doctrine of the *rabbis* or Jewish teachers subsequent to the Mosaic law, and which had its commencement about the time of the dispersion. It is considered to have derived its origin from the teaching of the Pharisees, mingled with Greek and other foreign elements. The followers of Hillel and Schammai, who flourished respectively about the commencement of the Christian era, formed the two leading schools of Rabbinism. [TALMUD; TARGUM.] The most brilliant period of Rabbinism was in the twelfth century under the teaching of Aben Ezra and Maimonides in Spain. The latter is the compiler of the thirteen articles which may be termed the modern creed of Judaism; establishing the unity and spiritual nature of God; the inspiration of Moses and the Prophets; the immutability of the Mosaic law; future rewards and punishments; and the expectation of the Messiah. Since that period, Rabbinism has either degenerated into mere formalism and puerilities, or expanded into a kind of philosophical Deism.

Rabbit. The *Lepus cuniculus* of Linnæus, a well-known domesticated rodent, which in its wild state is distributed over the whole of the northern hemisphere.

Rabdomancy. [RHABDOMANCY.]

Raca. An ancient Syriac word, signifying vanity or folly, and pronounced by the Jews with certain gestures of indignation. (Matt. v. 22.)

Race (Fr.). In Anthropology. [MAN; TEUTONIC.]

RACE. In Language. By philologists, nations or tribes which are found speaking the same language, or closely allied dialects, are said to belong to the same race. The expression conveys a certain amount of truth, but it must be used with great caution and within strictly defined limits. When it is said that the English soldier struggling with the Hindu sepoy during the mutiny of 1857 did not know that his enemy was his kinsman, this must be taken to mean that he was ignorant of the affinity of their several dialects, and of all that is implied in this affinity. This agreement, whatever be its measure, certainly proves that the ancestors of the Englishman and of the Hindu either belong to the same stock, or have at some time or other been thrown together; it shows further that from the same source they derive to some extent not only their civilisation, but their modes of thought. It is almost certain that they must in some measure share a common blood; but to what extent they may be anthropologically connected, it may be either difficult or impossible to ascertain. In Great Britain, English, Gaelic, and Welsh are spoken in different parts of the country. This fact proves that Teutonic and Celtic tribes have been brought together; and if, as in England, the Teutonic dialects predominate, this shows that at some time or other some tribes belonging to the Teutonic race were dominant in this country; but it does not hence follow that the great body of the English people are Teutonic, although a certain proportion of them must be. In other words, the population of this country is a mixed race; and although there is no such thing as a mixed language [LANGUAGE], an ethnological race is rarely, if ever, found altogether unmixed. Invasion, conquest, emigration, colonisation have constantly interfered with their purity. Hence the attempt to classify ethnological races or tribes by their languages can lead only to error. The fair Tahitian would thus be proved to be closely akin to the black natives of the Fiji islands. In Professor Max Müller's words, 'The science of language and the science of ethnology have suffered most seriously from being mixed up together. The classification of races and languages should be quite independent of each other. Races may change their languages, and history supplies us with several instances where one race adopted the language of another. Different languages may be, therefore, spoken by one race, or the same language may be spoken by different races; so that any attempt at squaring the classification of races and tongues must necessarily fail.' (*Lect. on Language*, first series.)

Raceme (Lat. racemus, *a bunch of grapes*). In Botany, a form of inflorescence, in which the flowers are stalked along a common unbranched axis, as in the Hyacinth and the Currant.

Racemic Acid (Lat. racemus). An acid found, together with the tartaric acid, in the tartar obtained from certain vineyards on the Rhine. It is the *paratartaric acid* of Berzelius. It is less soluble in water than tartaric acid, and differs in the form of its crystals and in its salts. It is *isomeric*, and has the same equivalent with tartaric acid. [TARTARIC ACID.]

Races. A name denoting particular spots in the sea where the water is disturbed by the meeting of two rapid currents, and not, as is supposed by sailors, by rocks projecting from the bottom of the sea. By the inhabitants of the Orkney islands, these races are called *roosts*.

Rachilla (Gr. ῥάχις, *a spine*). In Botany, a branch of inflorescence; the zigzag centre, upon which the florets are arranged in the spikelets of grasses.

Rachis (Gr. ῥάχις). In Botany, a branch which proceeds in nearly a straight line from the base to the apex of the inflorescence of a plant. The term is also applied to the main axes of the leaves of ferns.

RACHIS. A term applied by Illiger and other zoologists to the vertebral column of mammals and birds.

Rachitis (Gr. ῥαχῖτις, from ῥάχις, *the spine*, the part principally affected). The rickets. A disease generally confined to childhood, known by a large head, protruded breast-bone, flattened ribs, tumid belly, emaciated limbs, and great general debility; the bones in general, and especially the spine, are variously distorted and deficient in bony matter. The system occasionally rallies from this state as growth advances, but more or less deformity remains. Tonics, cold bathing, regular and proper exercise, very careful nursing, and occasionally rhubarb and tonic aperients, are the principal remedies; and where particular bones are inclined to bend, attempts must be made to throw the weight off them. This disease is frequently symptomatic of a scrofulous state of the glands and viscera; the stomach and bowels are always greatly deranged; and as there appears to be a deficiency of the hardening matter of the bones, various salts of lime, and even phosphate of lime, have been prescribed; the only apparent use of these last-named remedies is to render the gastric juice less acrid and acid.

Rack (A.-Sax. racan). An instrument of torture formerly used in England. According to Coke (who, however, merely reports the story on traditional authority), the rack was first introduced into the Tower by the duke of Exeter, constable of the Tower in 1447; and thence called *the duke of Exeter's daughter*. (3 *Inst.* p. 34.) Stowe, in his *Chronicle*, says that the duke's daughter herself invented it. The earliest mention of the use of the 'rack or brake' is by Holinshed, under the year 1467. But it first became common in the reign of Henry VIII. Under that prince, the remaining Tudors, James I. and Charles I., down to 1640, the rack was a common implement of torture for prisoners confined in the Tower, and inflicted by a warrant of the council or under the sign manual. The rack consisted of an oblong frame of wood, composed of four beams a little raised above the ground; the sufferer was fastened by the hands and feet to the corners, where two cross beams joined the longer ones, sometimes by small cords attached to each finger and toe; and the cords were twisted by means of rollers, so as to raise him from the ground, and stretch his body with extreme violence, dislocating the limbs, and, according to the Jesuit writers, who have left the most vivid representations of the sufferings of their companions under the state persecution of Elizabeth, sometimes extending the sufferer 'more than a palm beyond his usual stature!' (Jenner, *Societas Europæa*, p. 12; Jardine's *Reading on the Use of Torture in England*, 1837.) The Roman *equuleus* is often translated *rack* by English writers; but whether the equuleus was something similar to the English engine, or a wooden *horse* (as the derivation of the word implies), or, in short, what was its form and description, antiquaries have not been able to discover. (See, among other authorities, the learned treatise of Magius *De Equuleo.*) [QUESTION; TORTURE.]

RACK. In Machinery, a rectilinear sliding piece, having teeth cut on its edge so that they may work with those of a wheel or pinion which drives or follows the rack. The rack may be regarded as a toothed wheel whose radius is infinite.

Rack Rent. [RENT.]

Racovians. In Ecclesiastical History, the Unitarians of Poland are sometimes so called; from Racow, a small city of that country, where Jacobus à Sienna, its head, erected a public seminary for their church in 1600. Here the *Racovian Catechism*, originally composed by Socinus, and revised by his most eminent followers, was published. (Mosheim, *Eccl. Hist.* cent. 16, sec. 3.)

Radiant Heat. When a hot body is freely suspended in air, it cools down to the temperature of surrounding objects; when suspended in a space void of air, it still cools down. The chilling, in part in the former case, entirely in the latter, is caused by a process termed *radiation*: the investigation of the phenomena which attend the emission, transference, and stoppage of these rays forms the science of radiant heat. For a long time it was thought that this cooling took place by the hot body darting out from its substance particles of what was termed the matter of heat or caloric, the presence of which constituted warmth. These particles impinging on our sensory nerves caused the sensation of warmth, in the same way as the matter of light emitted from a luminous source falling on the retina was supposed to produce the impression of light. [LIGHT.]

This theory, so long held as regards the propagation both of heat and of light, has now given way to another which completely satisfies experimental and mathematical enquiry. This is the undulatory theory, already explained under the article LIGHT. Precisely the same reasoning there employed can be applied to the passage of heat through space.

The warmth of a hot body is supposed to be due to a state of rapid vibration amongst the particles of the substance, just as the sound of a bell is caused by the motion of its mass. When a bell suspended by strings is set in motion within an exhausted receiver, its ringing cannot be heard until the air is admitted. By means of the intervening air the vibrations of the sounding bell are taken up and communicated in pulses to the ear. By a similar but hypothetical medium called the ether, the vibrations of a hot body are transmitted in a series of waves to the sensory nerves. Radiant heat thus defined consists of this undulatory motion of the ether, a motion which travels through space with the velocity of light; and, as it does not in the slightest degree raise the temperature of the medium by which it is propagated, it passes through space without loss.

Since the early edition of this work appeared, the science of radiant heat has grown to such an extent that the few lines which were sufficient to describe its phenomena in 1840 could now

be replaced by a voluminous work. Owing to this, it will be necessary, in order to give a clear and succinct view of its varied phenomena, to class them under different heads.

Apparatus.—The apparatus now employed for investigations on radiant heat was first introduced by an Italian philosopher named Melloni, and is of the most perfect character. It consists of an instrument called a *thermo-electric pile*, by which small changes in temperature are rendered sensible by the production of an electric current, the strength of which is measured by its power of deflecting the needle of a sensitive galvanometer. [THERMO-ELECTRICITY.] It has been found by experiment that rock salt has the property of transmitting radiant heat with scarcely any diminution of the rays; hence this substance, as well as the thermo-pile, are indispensable in researches on radiation.

Fundamental Laws of Radiant Heat.—1. Radiation takes place and is transmitted through a vacuum as well as in air. This was proved by Count Rumford and Sir H. Davy at the beginning of this century. 2. Heat is emitted in a right line from every point on the surface of a hot body, spreading therefore in all directions round such a body. 3. Its intensity in a vacuum varies inversely as the square of the distance from the radiating point. 4. The amount of radiation, or the rate at which a body parts with its heat, is proportional to the excess of the temperature of the body above that of the medium in which it is placed. This law, though assumed by Newton, is found by experiment to hold good only within a certain range of temperature, not exceeding 50° of Fahrenheit. At higher temperatures Dulong and Petit found the rate of cooling to be more rapid than in the ratio stated. 5. All bodies placed in an enclosed space assume in time the temperature of the enclosure. 6. The intensity of the heating ray is as the sine of the angle which it makes with the surface. This law, however, is not general. 7. The nature of the source, as will subsequently be seen, greatly modifies both the intensity and quality of the radiation.

The only satisfactory hypothesis of the radiation of heat was that enunciated by Prevost of Geneva, about the year 1790, and known under the name of the *theory of exchanges*. Its leading principle is that all bodies are perpetually exchanging their heat with one another. It follows, therefore, that radiation takes place with greater or less intensity at all temperatures; that it is reciprocal between distant bodies; and that it subsists when the temperatures are equal, though in this case no alteration of temperature takes place, for each body then receives as much as it emits: this state is called the mobile equilibrium of temperature. This theory readily explains the apparent radiation of cold, such as is experienced when a block of ice is held near the face. In this case, although an interchange of heat still takes place, the human face, being the warmer body, emits more rays than it receives from the ice; hence its temperature sinks, and we feel chilled.

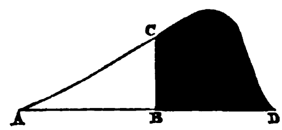
Phenomena analogous to Light.—We have already seen that the *intensity* of radiant heat, like that of light, diminishes as the square of the distance from the source. The *reflection* of radiant heat must have been a matter of common experience from the earliest times. The first systematic experiments which established this property were made by De Saussure and Pictet, by means of concave metallic mirrors. While engaged in these experiments, they found that radiant heat passed through a space of 69 feet in an inappreciable time. With more delicate apparatus Melloni subsequently established the strict analogy between the reflection of light and radiant heat, showing that the incident and reflected rays form the same angle with a perpendicular to the reflecting surface, and that reflection takes place in the plane of incidence. Leslie, and more perfectly Melloni and De la Provostaye and Desains, made a number of experiments on the reflecting power of bodies. The metals, though the best reflectors, differ among themselves, silver being the best, and iron the worst reflector. All polished metallic surfaces are good reflectors of heat, the reflecting power diminishing as the surface becomes tarnished or blackened. This fact has many familiar illustrations. Burning mirrors are constructed on the principle of the reflection of heat, the heat rays reflected from a concave mirror being brought to a focus just as is the case with the light. In roasting meat a polished metal screen is placed around the joint; the radiant heat from the fire, which otherwise would escape the joint, being reflected on to it by this means. The polished fire irons before a fire are never warmed by the heat radiated by the fire, because all the heat that falls on them is reflected from their surface. Besides being thus regularly reflected, a part of the heat which falls upon a surface is scattered in all directions, or, as it is termed, *diffused*. With rude apparatus Sir William Herschel examined the power of scattering heat possessed by various surfaces, and found that white paper scattered most heat and light, and black velvet least. The heat not thus regularly or irregularly reflected from a body is either absorbed by the substance being lodged within it, or transmitted through the body as light is transmitted through transparent substances. The *absorbing* power of a body is inversely proportional to its reflecting power, a good absorber being a bad reflector. On the other hand, the properties of absorption and radiation are reciprocal: the good absorber is a good radiator, or vice versâ. It follows from this that culinary vessels intended to receive heat should not be bright, but blackened; at the same time, vessels, such as urns and teapots, intended to retain heat, should not be of earthenware or painted, but of polished metal. We shall subsequently examine more

in detail the absorption of heat by various solid, liquid, and gaseous substances.

Like light, radiant heat can be *refracted* by means of suitable lenses. In the year 1800, Sir William Herschel first established the fact of the refraction of heat by a series of careful experiments. He converged the solar rays and the radiation from a heated stove by means of a glass lens, and found that there was a focus of heat a little beyond the focus of light formed by the lens. The *double refraction* of heat by a prism of Iceland spar was discovered by M. Bérard, who also was the first to announce the *polarisation* of heat. Employing more delicate apparatus, Principal Forbes subsequently verified this fact, using thin plates of mica for the purpose of polarisation. These facts were successively examined and firmly established by the experiments of Melloni. This philosopher has, however, gone further, and opened up an entirely new field of investigation, in the discovery that the invisible rays of heat possess different qualities like the differently coloured rays of the visible spectrum. Light which has passed through a glass of a certain colour, passes through another glass of the same colour far more freely than through any other coloured glass. The same phenomenon is exhibited by radiant heat; for, after passing through one plate, it will traverse with freedom a number of other plates of the same material, though it may not be able to pass through a plate of another substance. It follows, therefore, that the invisible rays of heat must differ in a manner analogous to the coloured rays of the spectrum. This heat-colouration Melloni named *thermocrosis*.

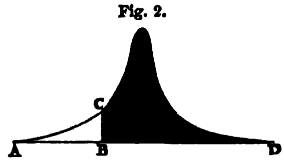
All the foregoing phenomena show the close relationship existing between radiant heat and light. No fact in the one is without its parallel in the other; and this wonderful coincidence has led philosophers to the belief that one is but a modification of the other: light consisting of undulations in the ether of a certain length which increases from violet to red, and radiant heat of similar undulations of a length greater than the red. This will be shown more clearly in the next section.

Heat of the Spectrum.—Sir William Herschel in the year 1800 examined the temperature of the different colours of the solar spectrum by means of delicate thermometers. He found the temperature to increase as he approached the red end: going into the obscure region beyond this point, he still found the temperature to rise; the thermometer indicating 7° Fahr. in the full red, whilst in the dark rays beyond the red it rose to 9° Fahr. By means of a linear thermo-electric pile, and a rock-salt lens and prism, Melloni made a series of accurate experiments on the heating powers of the solar spectrum, which corroborated Sir William Herschel's observations, and established the fact that the maximum temperature of the spectrum lay in the dark space beyond the red. Since Melloni's time, Prof. Müller has re-examined the solar spectrum, and represented the heating effect by the following curve, fig. 1. The luminous part of the spectrum is included within the space ABC,



whilst the non-luminous heat-rays are included in the dark space BCD. These dark rays are known as the extra or ultra red rays, or sometimes as the Herschelic rays. Very recently Prof. Tyndall has investigated with great care the spectrum of the electric light, using similar apparatus to that employed by Melloni. As in the solar spectrum, Tyndall found the heating effect to rise from the violet, where it was *nil*, to the red, and increase to a maximum in the dark space beyond the red. A graphical representation of the electric spectrum (fig. 2) was constructed as in the case of the solar spectrum. The distribution of heat in the two spectra are dissimilar, the extra-red rays BCD being largest in amount in the radiation from the electric light, and towering over the portion occupied by the visible spectrum ABC. It has, however, been proved by Tyndall that when a thin layer of water is interposed in the path of the rays of the electric light, the shape of the curve becomes similar to that obtained from the solar rays at the earth's surface. It is therefore probable that the diminution of the extra-red rays in the solar spectrum is

Fig. 2.



owing to their partial absorption by the aqueous vapour in our atmosphere, an hypothesis supported by recent observations.

The luminous spectrum is only the visible central part of the rays of the sun or the electric light decomposed by a prism, for innumerable dark rays fall beyond both ends of the spectrum. The invisible rays beyond the violet were first rendered visible by Prof. Stokes. [FLUORESCENCE.] Sir Wm. Herschel endeavoured to render visible the invisible rays beyond the red, by cutting off the luminous spectrum and condensing the extra-red rays by means of a lens. His attempt was unsuccessful, and it is only recently that this has been accomplished by Prof. Tyndall in the following manner. A concave mirror about five inches in diameter was placed behind the electric light, and its intense radiation thus converged to a focus about six inches distant. Between the luminous focus and the electric light was interposed a solution of iodine in bisulphide of

carbon contained in a glass cell two inches deep. This solution has the power of stopping all the light, i.e. of absorbing the rays A B C, fig. 2, whilst it transmits the obscure rays represented by B C D, fig. 2. An intensely hot but invisible focus was thus obtained, at which black paper could be inflamed, a cigar lighted, and the more fusible metals melted or burnt. When a piece of thin blackened platinum was held in the dark focus, it was immediately raised to a white heat; and thus the non-luminous rays beyond the red were rendered luminous, and the identity of the agent which produces light and radiant heat was established. To this phenomenon Prof. Tyndall has given the name *calorescence*.

Emission of Heat.—In the preceding section prismatic analysis reveals the fact that the larger portion of the radiation from luminous bodies consists of invisible rays of heat. To determine the actual ratio which exists between the light and heat radiated from a luminous source, it is only necessary to measure the total radiation, and then suppress either the luminous or obscure portion, by interposing suitable absorbents in the path of the rays. Melloni did this by cutting off the obscure heat by means of a layer of water, a liquid which he found impervious to the radiation from bodies heated under incandescence. More recently Tyndall has checked these determinations by withdrawing the luminous radiation by an opaque solution of iodine in bisulphide of carbon, and measuring the amount of obscure rays, which were wholly transmitted by this *ray filter*. Various sources examined in this manner gave the following proportion of luminous and obscure rays in every 100 emitted; the sum of both is, of course, the total radiation.

	Luminous	Obscure
Dark spiral	0	100
Red-hot spiral . . .	0	100
Hydrogen flame . . .	0	100
Oil flame	3	97
Gas flame	4	96
White-hot spiral . . .	4·6	95·4
Electric light . . .	10	90

Every luminous ray is converted into its equivalent of heat when it falls upon and is absorbed by the blackened face of the thermo-electric pile. Hence it appears that the calorific equivalent, or amount of force, corresponding to the luminous rays emitted from a hydrogen flame, or even a red-hot spiral, is absolutely insensible when compared with their obscure radiation; and that in the intensest artificial light only 10 per cent. of the whole emission consists of luminous rays. These remarkable facts must increase our admiration of the wonderful structure of the eye, as they show the extraordinary sensitiveness of the retina to the impression of light.

When various substances are raised to the same temperature, they do not all emit the same amount of heat. Leslie examined these differences in the radiating power of a great number of bodies. Coating the sides of a cubical canister (now known as a *Leslie's cube*) with various substances, he found that lampblack, white lead, and all organic bodies were the best radiators, whilst the metals were the worst. The radiating like the absorbing power of a body is exactly the reverse of its reflecting power: a good radiator is a bad reflector. With more delicate thermometric apparatus Tyndall has recently determined the emissive power of various powders, which were attached to the sides of a Leslie's cube heated to 212° Fahr. The radiation from the metal surface of the cube being equal to 15 units, that from other substances coating this surface is given in corresponding units in the following table:—

Substance	Radiation
Rock salt	35·3
Biniodide of mercury . .	39·7
Sulphur	40·6
Vermilion	46·6
Fluor spar	68·4
Carbonate of lime . . .	70·2
Red oxide of lead . . .	74·2
Oxide of cobalt . . .	76·7
Sulphate of lime . . .	77·7
Red oxide of iron . . .	78·4
Hydrated oxide of zinc . .	80·4
Lampblack	84·0

As these substances are of different colours, the experiments are a test of the influence of colour on radiation. At this temperature colour is seen to be without any effect on the radiative power; for the feeblest radiator, rock salt, and one of the most powerful, oxide of zinc, are both white; biniodide of mercury and oxide of lead are both red, but their radiating powers are very different.

Absorption of Heat.—Melloni laid the foundation of this branch of radiant heat by a careful and elaborate investigation of the transmission of heat through solids and liquids. The solid substances examined by him were cut into plates 0·1 of an inch thick. After noting the effect produced by the radiation from this source when nothing intervened, the little plate was interposed, the diminution which it effected being then observed. Melloni successively tried four different sources of heat, determining in each case the transmission through the same bodies.

	Oil lamp	Incandescent platinum	Copper at 750° Fahr.	Copper at 212° Fahr.
Rock salt	8	8	8	8
Sulphur	26	23	40	46
Fluor spar. . . .	28	31	58	67
Rock crystal . . .	62	72	94	97
Glass	61	76	94	100
Black glass . . .	74	75	88	100
Common gum . . .	82	97	100	100
Alum	91	98	100	100
Ice	94	100	100	100

If the total radiation from each source be represented by 100, the numbers in the foregoing table express the proportional quantities of heat intercepted by some of the principal substances examined; showing that different bodies, though they may be of equal transparency to light, possess very different powers of transmitting heat, and that with one exception the heat of the different sources is transmitted in different degrees by the same body. To express the power of transmitting heat, Melloni gave the name *diathermancy*; whilst the power of intercepting heat he called *athermancy*. Melloni made rock salt perfectly diathermic for all sources of heat; the 8 per cent. which it failed to transmit he attributed to loss by reflection from its surfaces; but a stricter examination by Tyndall has discovered that even rock salt absorbs a small proportion of obscure rays. The table shows that a transparent plate of glass one-tenth of an inch thick intercepts all the heat radiated from a cube of boiling water, that a plate of alum of equal thickness is opaque to all bodies heated under incandescence, and that a similar film of ice transmits only 6 per cent. of the radiation from an oil lamp. As ice is perfectly transparent to light, the reason for its opacity to the heat of the red-hot spiral, and its small transmission of the heat from the lamp, becomes explained by reference to the last section, where it is shown that in all luminous sources the light rays bear a very low ratio to the obscure.

Melloni also examined the transmission of heat through *liquids*. These he enclosed in a little cell with glass sides; the thickness of the liquid layer was 0·36 of an inch, and the source of heat an oil lamp surrounded by a glass chimney. Out of every 100 rays Melloni found,

Bisulphide of carbon absorbed	37
Olive oil	70
Naphtha	72
Ether	69
Sulphuric acid	83
Nitric acid	85
Acetic acid	88
White of egg	89
Water	89

These numbers express the absorption by the liquid *plus* the absorption by the glass sides of the cell, which latter, from the quality of the heat employed, must have been large.

As besides this the experiments of Melloni are not entirely free from error, Professor Tyndall has recently determined with more perfect apparatus the transmission through liquids. The source of heat here employed was a spiral of platinum wire, which was raised to a bright red heat by the passage of an electric current. The liquids were enclosed in a cell with movable rock-salt sides, so that liquid layers of varying thickness were obtainable. In the following table are given the absorptions per cent. of different liquids at the thicknesses mentioned.

	Thickness of liquid in parts of an inch		
	0·02	0·07	0·27
Bisulphide of carbon	5·5	12·5	17·3
Chloroform	16·6	35·0	44·8
Benzol	43·4	62 5	73·6
Ether	63·3	76·1	85·2
Alcohol	67·3	83·6	89·1
Water	80·7	88·8	91·0

As in the case of solids, large differences are seen to exist between the absorbent power of various liquids. Though all the substances in the foregoing table are transparent to light, yet between the first and last in the list a difference of more than 75 per cent. exists in the power of transmitting heat.

The elegance of Tyndall's arrangement was further shown in his perfect control over the temperature of his source. This he could elevate by merely increasing the strength of the electric current which passed through the spiral. The temperature being thus gradually raised from below incandescence to vivid whiteness, the proportion of heat transmitted was found steadily to increase. This Melloni had previously discovered, deducing from his observations a law that the penetrative power of radiant heat increases with an increase of temperature of the source. But, whilst the experiments just mentioned confirm this law, Knoblauch and more lately Tyndall have shown that it is not in all cases true. For example, the latter found that of the radiation from a hydrogen flame 99 per cent. was absorbed by a layer of water 0·07 inch in thickness, and the whole radiation was entirely intercepted by a layer of water 0·27 of an inch thick. With a red-hot spiral, though the temperature of this source is far lower, layers of water at the same thicknesses absorbed 89 and 91 per cent. respectively.

But besides solids and liquids, *gases* and *vapours* are found to absorb very marked and different amounts of radiant heat. Tyndall has entirely created this branch of investigation. To him we owe the discovery and laborious examination of the absorption of heat by gaseous bodies. The limits of this work forbid a description of the apparatus employed in these experiments; we shall therefore merely give a summary of the results obtained. It was found that oxygen, hydrogen, and nitrogen, or a mixture of these gases, absorb an inappreciable amount of heat, whilst many of their gaseous combinations were powerful absorbents. The following table gives the absorptions by various gases relatively to the amount of heat intercepted by air, which was taken as unity. The gases were successively allowed to fill a glass tube nearly three feet long, the source of heat being a plate of copper heated by a gas flame.

	Relative absorption
Air	1
Oxygen	1
Nitrogen	1
Hydrogen	1
Chlorine	39
Carbonic acid	90
Sulphurous acid	710
Olefiant gas	970
Ammonia	1195

Subsequently Professor Tyndall examined some of these gases contained in a brass tube fifty inches long, using the same source of heat as before. The results given in the next table are absolute absorptions, the total radiation through the exhausted tube being taken as 100.

	per cent.
Carbonic oxide absorbed	13
Carbonic acid	14
Nitrous oxide	33
Olefiant gas	77

Preserving the experimental tube of the same length, Professor Tyndall has first examined the effect of diminishing the pressure of the gas within it; and then, keeping the pressure of the gas constant, he has investigated the effect of diminishing the length of the gaseous column. In the first case, up to a certain point the absorption was found to be exactly proportional to the density of the gas; but in the second case, even with the thinnest layers, the absorption generally increased less rapidly than the thickness. Four gases were submitted to experiment, the length of their columns being gradually increased from 0·01 of an inch up to 50 inches.

A layer of olefiant gas 0·01 of an inch thick absorbed nearly 2 per cent. of the radiation from a heated plate of copper, a column of the same gas 2 inches thick intercepted about per cent., and a column 2 feet thick absorbed nearly 70 per cent.

The absorption by vapours has also been examined, and as great differences found to exist among these bodies as among gases. The liquids from which they were derived were contained in a little flask, and each vapour was admitted into the tube until a pressure of half an inch was indicated by an attached barometer gauge. Here are the results with the same length of tube and the same source of heat as employed in the measurements given in the last table:—

	per cent.
Bisulphide of carbon vapour absorbed	8
Chloroform	17
Benzol	20
Alcohol	47
Ether	53
Acetic ether	64

Hence the vapour of chloroform, one of the feeblest, at a pressure of $\frac{1}{60}$ of the atmosphere absorbed more heat than a whole atmosphere of carbonic acid gas. The vapour of water could not be examined directly as the other vapours, but numerous experiments conducted in other ways showed that this of all vapours was probably the most powerful absorbent of heat. The importance of this fact as explaining many perplexing phenomena in meteorological science will be at once evident.

Perfumes have been subjected to examination by Tyndall, and the absorption by various kinds have been measured. The odour of patchouli absorbed the least heat, and of spikenard and aniseed the most. The almost inappreciable quantity of matter contained in these odours, and yet their strongly marked action on radiant heat, is a striking and suggestive fact.

A strict comparison of the absorption of heat by certain liquids and by proportional quantities of the vapours derived from them, showed that the order of absorption was in both cases the same. The position of a liquid as an absorbent is the same as that of its vapour, and hence it is probable that from these experiments the general law can be deduced that the relative power of absorption possessed by any body is independent of its state of aggregation.

The *radiating* powers of gases and vapours have been investigated by Tyndall. The method chiefly employed was very novel, and consisted in making the gas, whose radiative power was to be determined, heat itself by rushing into the vacuous experimental tube. The particles of the gas were warmed by their impact against the tube, and radiated their heat to the pile. In these experiments both sources of heat were removed, and the end of the tube remote from the pile was closed by a plate of metal, the rock-salt plate remaining at the other end. In this way Tyndall has demonstrated that the radiative power of every gas or vapour is directly proportional to its absorptive power: an important extension of that law which was first proved, in the case of solids, by the experiments of Leslie.

Radiant Point of Shooting Stars. [METEORS, LUMINOUS.]

Radiants. In Geometry, straight lines of unlimited length proceeding from a point. The term *pencil of rays* is more frequently employed to denote the same thing. [PENCIL.]

Radiaries. [RADIATA.]

Radiata (Lat. radius, *a ray*). The name given by Cuvier to the lowest organised of the primary divisions of the animal kingdom; because certain of the animals therein included have a radiated form of a part or the whole of their body. [ACRITA; NEMATONEURA; PROTOZOA; ZOOPHYTA.]

Radiating Point. Any point from which rays of light or heat proceed.

Radiation (Lat. radiatio, from radius, *a ray*). The emission of light or heat from a luminous or heated body. The principal laws of radiation have already been given under the article RADIANT HEAT; but the subjects included under the present head are more particularly the phenomena of solar and terrestrial radiation.

The force of solar radiation is measured by the excess of the temperature which a body assumes when exposed to the direct action of the sun's rays above that which it has when turned towards space away from the sun. This excess may be roughly determined by two common thermometers, one placed in the shade, and the other exposed to the sun and having its bulb blackened to prevent reflection. A more accurate means was, however, devised by Sir John Herschel, who, with an instrument called by him an *actinometer*, has measured the heat received from the sun at the Cape of Good Hope. M. Pouillet has also executed a series of measurements on solar radiation, employing for this purpose an instrument which he named a *pyrheliometer*. By these experiments the amount of solar heat falling in a given time on a surface of known area was ascertained, from which the value of the heat which the earth annually receives from the sun was deduced. This amount is equal to that which would melt a stratum of ice 102 feet thick encrusting the whole earth. Having found the quantity of solar heat intercepted by the earth, the entire amount emitted by the sun can be calculated. This is 2,300,000,000 times more than we receive, it would boil 700,000,000,000 of cubic miles of ice-cold water per hour, and in one year it is equal to the heat produced by the combustion of a layer of coal seventeen miles thick entirely surrounding the sun.

The amount of heat received from the sun diminishes as the thickness of the air traversed by the sunbeams increases. When the sun is at the horizon the absorption by our atmosphere is therefore greatest, when at the zenith it is least. In this latter position M. Pouillet estimated our atmosphere absorbed 25 per cent. of the solar radiation; but a far higher proportion of terrestrial radiation is intercepted. This has been established by Professor Tyndall, who has discovered that the main absorbent in our atmosphere is not the large body of oxygen and nitrogen of which it is composed, but the small amount of aqueous vapour it always contains. The presence of aqueous vapour in the air is thus shown to be of essential importance in climate.

While the earth is receiving heat from the sun, it is continually radiating its own warmth into space. This loss is more than compensated during the day, but at night the terrestrial radiation causes the condensation, and sometimes the congelation of the moisture in the air. Dew in summer and hoar frost in winter are thus produced on the surfaces of those bodies which are the best radiators, such, for example, as are all animal and vegetable structures. From the theory of terrestrial radiation, a curious deduction was made by Fourier, with regard to the temperature of the region of space through which the earth moves in its orbital revolution: this he estimated to be $-58°$ Fahr., but Pouillet has more recently made the temperature of space to be $-175°$ Fahr.

Radical. [ORGANIC RADICALS.]

Radical Axis of Two Circles. Two conics intersect one another in general in four points, and have, consequently, six common chords. In the special case of two circles four of these chords are always imaginary, and one at infinity [CIRCULAR POINTS AT INFINITY]; the fifth, and only remaining common chord, however, is always real, whether the circles intersect or not, and is called their *radical axis*, a name proposed by Gaultier of Tours. (*Journal de l'École Polytechnique* 1813.) One of the characteristic properties of the radical axis, which leads at once to its construction in the case of two non-intersecting circles, is that the tangents to the two circles drawn from any point of it are equal. Circles having the same radical axis are said to be *co-axal*; they possess many remarkable properties. The circles of a co-axal system will either intersect each other in the same two points, or not intersect at all. In the latter case there will be two *point circles* in the system; these are called the *limiting points*. Every circle whose centre is in the radical axis, and which cuts one of the co-axal circles perpendicularly, cuts all in the same manner: all circles thus drawn constitute a second *conjugate* system of co-axal circles whose common radical axis is the line of centres of the first system. Of two such conjugate systems of co-axal circles one has always limiting points and the other not. The inverse circles to those forming a co-axal system are also co-axal, and their reciprocals form a system of confocal conics. In the works of Poncelet, Chasles, and Steiner, as well as in the more recent English text-books and journals, the properties of co-axal circles are frequently discussed.

Radical Bass. In Music, the same as FUNDAMENTAL BASS.

Radical Centre of Three Circles. The point of intersection of the three radical axes of the circles, taken in pairs. It is the centre of the only circle which can be drawn to cut each of the three circles orthogonally.

Radical Reformers. In Politics, a name applied to that political party in England which desires to have the abuses which, from lapse of time or any other cause, may have crept into the government, completely *rooted out* (as the term implies), and a larger portion of the democratic spirit infused into the constitution.

Radical Sign. In Algebra, the symbol $\sqrt{}$, denoting the extraction of a root. It is a modification of the letter *r*, the initial letter of *radix* or root. To distinguish the particular root which is to be extracted, a number is prefixed to the symbol; thus, $\sqrt[2]{}$, $\sqrt[3]{}$, $\sqrt[4]{}$, &c. denote respectively the square root, cube root, fourth root, &c.; but as the square root or second root was the first considered, the number is usually omitted, and merely the symbol $\sqrt{}$ written. Fractional exponents are frequently used instead of the radical sign. A *radical quantity* is a quantity to which the radical sign is prefixed.

Radicle (Lat. radicula, dim. of radix, *a root*). In Botany, that portion of an embryo which eventually becomes the descending axis or root. It is the lowest of the two opposite cones of which an embryo plant consists.

Radiolite. A variety of Natrolite from Brevig, in Norway.

Radiolites. A genus of fossil shells, the inferior valve of which is in the shape of a reversed cone, the superior valve being convex.

Radius (Lat.). In Fortification, the *oblique radius* is a line drawn from the centre of the polygon to the extremity of the exterior side; the *right radius* is a line drawn from the same centre perpendicular to the exterior side.

RADIUS. In Geometry, the line drawn from the centre of a circle to any point in its circumference.

RADIUS. In Osteology, a bone of the fore-arm; so called from its supposed resemblance to the spoke of a wheel. Its upper end, which is the smallest, is formed into a round hollowed head, and is articulated with the small head at the side of the pulley of the humerus, whilst the rounded border of it next the ulna is articulated with the lesser sigmoid cavity of that bone; its lower extremity is articulated with the bones of the wrist.

Radius of Curvature. The radius of the circle of curvature. [CURVATURE.] The length of the radius of curvature at any point of a plane curve, whose equation to rectangular coordinates is $f(x, y)=0$, is

$$\frac{(dx^2+dy^2)^{\frac{3}{2}}}{(d^2x\,dy-d^2y\,dx)}$$

which expression becomes simplified when x is taken as the independent variable and regarded as equicrescent, as then $d^2x=0$. If the curve be referred to polar coordinates r and θ, the radius of curvature is given by the formula

$$\frac{(dr^2+r^2d\theta^2)^{\frac{3}{2}}}{r^2d\theta^3+rdr\;d^2\theta+2dr^2d\theta-rd\theta d^2r}.$$

Radius of Explosion. In Military Mining, the line drawn from the charge to the edge of the crater.

Radius of Rupture. In Military Mining, the distance from the charge to the point at which the internal commotion caused by the explosion ceases.

Radius of Torsion of a Non-Plane Curve. [TORSION.]

Radius Vector (Lat. radius, and vector, *one who carries*). In Geometry, the line joining a fixed point or *pole* to any other point in space. The length of the radius vector is one of the *polar coordinates* of the point. [COORDINATES.]

Radix. In Mathematics. [ROOT.]

Raft (Dan.; A.-Sax. reaflan). A species of float formed of various logs or planks, fastened together side by side, so as to be conveyed from one point to another. This means of conveying timber to the sea-coast is practised in many places. The following is the plan adopted on the Rhine. A little below Andernach the village of Namedy appears on the left bank under a wooded mountain. The Rhine here forms a bay, where the pilots are accustomed to unite together the small rafts of timber floated down the tributary streams into the Rhine, and to construct enormous floats, which are navigated to Dordrecht, and sold. These machines have the appearance of a floating village, composed of 12 or 15 little wooden huts, on a platform of oak and deal timber. They are frequently 800 or 900 feet in length, and 60 or 70 in breadth. The rowers and workmen sometimes amount to 700 or 800, superintended by pilots, and a proprietor. The raft is composed of several layers of trees, placed one on the other, and bound together: a large raft draws not less than 6 or 7 feet of water. Several smaller rafts are attached to it, by way of protection, besides a string of boats loaded with anchors and cables, and used for the purpose of sounding the river and going on shore. The domestic economy of an English man-of-war is hardly more complete. Their navigation is a matter of considerable skill, owing to the abrupt windings, the rocks, and shallows of the rivers.

Rafts improvised of spars, barrels, planks, &c. often afford valuable aid in saving life and property in cases of shipwreck. For such purposes carefully bunged casks offer greater powers of flotation than almost any article on board ship.

RAFT. In Military Engineering, a floating movable bridge, consisting either of strong pieces of wood secured together, and covered with planks or boards, in which case it will not bear much weight; or of the same arrangement with casks secured underneath, when artillery can be passed over it.

Rafter (Sax. ræfter). In Architecture, an inclined piece of timber in the side of a roof; sometimes called a *spar*. [ROOF.]

Rag Stone. A dark grey silicious sandstone breaking with a rough or ragged fracture.

Ragman's Roll. A name of which no authentic derivation is extant (Jamieson's *Etymological Dictionary*), but which belongs to the collection of instruments by which the nobility and gentry of Scotland subscribed allegiance to Edward I. in 1296. They were preserved in the tower of London; and have been printed by the Bannatyne Club (1834).

Raguly (apparently from the Fr. ragué, used of a rope fretted by rubbing). In Heraldry, a line jagged or notched in an irregular manner. The old cognisance of the Nevilles, the *ragged staff*, is a *bâton raguly*.

Rail (Ger. riegel). In Architecture, the horizontal part in any piece of framing or panelling. Thus in a door the horizontal pieces between which the panels lie are called *rails*, whilst the vertical pieces between which the panels are inserted are called *styles*.

Rail or **Water-Rail** (*Rallus aquaticus*, Linn.). A native species of a genus of Macrodactyle or long-toed waders, destitute of alar spines or a frontal shield.

Railing. A fence or barrier made of posts and rails, whether of wood or iron. The most ordinary fence of this description in the country is formed of wooden posts let into the soil, so as to stand upright, to which are nailed or mortised horizontal wooden rails, one above another, at such a distance as to prevent domestic animals from penetrating through them. In some cases one horizontal rail is fixed to the posts near the ground, and another near the top of the post, the interval between them being rendered impenetrable to cattle by upright rails nailed to the top and bottom horizontal rails. Iron railings are generally formed in this manner, i.e. the bars are riveted to the bottom horizontal rail, and fixed to the upper rail by lead or any other contrivance.

Railroad or **Railway.** In Political Economy. The charge of carriage is one of the most important items in the cost of production and the distribution of commodities to consumers. So considerable is it in some cases, that bulky articles, however cheaply made in some countries or districts, cannot be transported even to regions where materials are scanty and labour dear, but must be manufactured on the spot. Every country, for instance, has common pottery works, and manufactures at least the cheaper kinds of wooden furniture. Under no circumstances would it be advantageous to add the cost of conveyance to the production of these articles, even though they could be supplied under the most favourable conditions. Similarly, some articles possess so much value in small bulk—as, for instance, precious metals, precious stones, and spices—that the cost of carriage becomes a comparatively small element in the aggregate price of the utility offered to the consumer. It is possible that, with due appliances of artificial heat and horticultural skill, every one of the spices produced in tropical countries could be grown under glass in England. But the increased cost of production would be so considerable, that no one would attempt the cultivation, unless for scientific purposes. Between these two classes of commodities, those which could not be carried because the cost of transit forms so large an element in the price, and those which would be carried under even the most imperfect means of transit, there is a very large class of objects, which if the cost of carriage be considerably reduced might be got from countries or regions in which they can be produced most cheaply, and thus their manufacture in countries where they are produced at greater cost might be superseded. Again, in the case of those commodities which are produced abundantly in one country, and not produced at all in another, but are nevertheless in demand, a reduction of the cost of carriage will bring their use within the power of those who have hitherto by reason of their dearness been debarred from the enjoyment or convenience. Thus, for instance, pepper is produced in certain tropical countries as profusely as haws are on English hedges, and from the remotest times has formed an ingredient almost necessary in cookery. Before the discovery of the Cape passage, pepper was carried by a tedious land passage across the plains of Central Asia to the coast of Syria, or through the highlands of Armenia to Trebizond, or by a sea passage (scarcely less expensive) from Ceylon to Aden, thence across the desert of the Nile, and down this river to Alexandria; hence it cost, when sold in England, about 1*s.* 6*d.* the pound troy, i.e. fully 10*s.* or 12*s.* in present values: or, to take a nearer case, there is no reason to believe that the price of tea is materially changed in China since the time, now about 180 years ago, when it first became an article of general consumption in this country. If any effect has been produced by the long-continued traffic, it naturally should be that of an increased charge. But so considerably has the comparative cheapness of carriage reduced the price of this article, that the same tea which in the days of the East India Company's monopoly and the slow voyaging of her sluggish merchantmen, cost 12*s.* the pound in England, may now be had for 2*s.* Lastly, since duties are and have been levied on the most important articles of foreign produce, especially those which are in a state immediately available for consumption, and since, in order to make the tax as light as possible to the consumer, the duty is paid at a time as near as possible to that in which the article is consumed, the existence of an easy system of transit and carriage will bring about that the least possible amount of duty-paid goods will remain in the hands of the retail trader, and thus that he will be enabled to offer his commodities at the lowest possible rate to the consumer. [SUPPLY; WAREHOUSE, BONDED.]

Now, overland, the charge of transit must, from the friction to be overcome, be vastly greater than that imposed on sea-borne goods. Even when a canal has been made, and great outlay incurred in making levels, building locks, and securing the sides of a canal from leakage, the reduction of cost is very great, in consequence of the vast diminution of friction by the use of water carriage. It will be obvious, too, that if a road could be constructed in which friction could be completely eliminated, and the only remaining difficulty to be overcome would be the resistance of the air, very little mechanical or manual force would be needed in order to move heavy weights over the plane surface, while by implication the reduction of such an amount of friction to the least amount would progressively approximate to the condition of an absolute removal of friction from the act of artificial motion, and the economical end, often adverted to, of attaining the greatest possible result with the least possible expenditure of force, would thus be reached. The advantage of using a plane surface was, of course, felt as soon as manual or other labour was employed in moving heavy bodies, and the act by which a

labourer drives a wheelbarrow up or along a plank has fundamentally the same purpose as the use of a tram or railway. These trams or railways have existed in mining and quarrying districts for a long time, and it is said that the duke of Bridgewater, of canal reputation, was aware that the only practical competition which could hereafter militate against his favourite method of canal traffic was the railway.

The course of scientific discovery and adaptation, which has developed the stationary into the locomotive engine, has produced a complete revolution in the means of land transit, both as to cheapness, efficiency, and speed. The conveyance of goods, which under the old system of heavy waggons, or the improved but imperfect method of canal navigation, was very long, necessarily very incomplete, and generally very expensive, has now been rendered easy and rapid, the time of transit having been diminished by one-fifth at least, and the service of the railway being much more general than that of canals. The cost, too, though not lessened in the same proportion, is considerably reduced. It is true that in the conveyance of heavy goods, the demand for which is pretty constant and the supply generally uniform, the slowness of canal traffic is no hindrance to business, and the barge can still compete successfully with the locomotive. But in the conveyance of all commodities for which speed is necessary, and occasionally even for the conveyance of the most bulky goods, the railway is superior to any other method of transit. For example, under the old canal system, a continual frost often produced a sort of coal famine in large towns, as well as other results now obviated by the services of railroads. The first advantage, then, which a railroad gives to trade, and by implication to the producer and consumer, is that it diminishes the cost of transit. This result, which is manifest enough in those objects which are immediately familiar to us, is of the highest national importance when we take into account its effects on home and foreign trade. The fertility, for instance, of any district, will be of very little value to its possessors, unless an easy method be supplied by which its produce can be brought to market. A good road is as great an object of interest to the agriculturist, as good cattle and good land. The real value of any estate, as far as the market price of its produce goes, is greatly relative to the ease and cheapness with which that produce can be offered for sale. In this particular, railroads have conferred prodigious benefits on landowners. They have at once equalised and raised prices. The market value of costly but perishable commodities has been almost doubled in certain districts by their operation. The stimulant given to production in the creation of a market for produce is very great. Meat, poultry, fish, fruit, vegetables, milk, butter, eggs, and a variety of other products, the consumption of which was once almost entirely local, and the price of which was consequently low, are now rated even in remote country places at town prices. Twenty or twenty-five years ago, legs of pork, the least valuable part of the pig with agriculturists in home consumption, could have been frequently purchased in the eastern part of Hampshire at from 3½*d.* to 4*d.* the pound, while fresh butter in summer rarely rose above 8*d.* the pound. These and similar low prices of poultry and fruit have been raised by the easy method of transit supplied by railroads. In all probability (for the elements of the calculation are wanting, owing to the absence of any compulsory registration of the titles to landed property), land in the neighbourhood of railways, i. e. the greater part of the land in England, has increased seventy-five per cent. in value, by this cause alone, during the last thirty years.

The effects of railways on foreign trade are still more noteworthy. Many conveniences and luxuries of life have been rendered accessible to the community by the beneficent agency of these iron roads. For instance, a great trade in foreign eggs and fruit is being carried on between this country and France. Such a trade would be impossible without easy and rapid communication. At the present moment a traffic is springing up in ripe grapes, brought from the South of France, the purpose of the importation being the use of these articles for the home manufacture of wine. No better illustration could be given of some of the advantage which may and does ensue upon the distribution of commodities and the division of human labour, than the introduction of such a traffic by the agency of a railroad.

Still more important, however, is the effect of railway communication on the supply of food. It is a continual subject of alarm among economists, that population in thickly settled countries is fast outgrowing the means of subsistence. This view is based partly upon the economical theory of Rent, partly on that of Population. But the contingency, on the hypothesis of sustained intercourse taking place between communities, and the strengthening of international interests, is so remote as hardly to deserve serious attention, still less to be a subject of alarm. Improvements in the conveyance of supplies by ships, in the shortening of voyages, the cheapening of materials, the abolition of duties on timber, are doing and will do much towards lessening the cost of food produced in countries where fertile land is boundless, and the cost of agriculture, as proved by the price of corn on the spot, is very low. But railroads have done even more than ships towards bringing about this result, and dispelling the alarms of those who have hitherto reasoned from imperfect data. If the reader will cast his eyes upon any map of the United States, and consider the network of railroads converging to Chicago, Detroit and Buffalo, and observe that they form a sort of trade drainage for the produce of the vast prairie lands in the western states; that railroads are laid as rapidly as their areas are

being brought into cultivation; that it pays the western farmer well to produce wheat for the English market at prices far below the average of those at which it was cultivated prior to the liberation of food from the trammels of the corn laws; and that the emigration into the United States, and the occupation of land, are progressing at a rate unparalleled in the history of any community which has ever grown before, the alarm of a deficient supply and a redundant population will be seen to be as baseless as any panic which has ever occupied men's minds. And it must be remembered that this area is only a portion of that which is being cultivated for food. The best districts of Canada are being rapidly occupied, and wheat of the best quality grown. The supply from these regions promises to be exceedingly abundant; for it is a fact in the culture of wheat, that its quality is always the better the nearer it approaches the isothermal line beyond which its cultivation is, by climatal reasons, impossible.

The economical history of railway enterprise in this country is by no means creditable to the national character or the public conscience. It could not, perhaps, have been expected that these undertakings should have been the act of government, not so much because they are not (like the post office) a branch of business which might have been very fairly carried out by government, but because administrations are inveterately prodigal, slovenly, and inefficient. The management, too, of railways in the hands of government would have been fruitful in all kinds of parliamentary and party jobs, and public opinion would probably have done little towards correcting abuses. Nor was it possible, according to the theory of property in land, and the permission given to landowners by the legislature to tie up and control its distribution by all sorts of complex conveyances, to construct these roads on the basis of mutual consent, or the consent of the majority of those through whose lands the railroad was to pass. Hence the purchase was compulsory, and effected by parliamentary sanction. But as the legislator was generally the landowner, it was necessary that terms should be made with him before his assent was given, and thus the landowners on various pleas contrived to exact enormous sums, under the name of compensation, for permission to use a part of their land, and, as events showed, to improve materially the remainder. It would be a curious enquiry to contrast the real value of the land taken for railways, and the price paid during the early years of these enterprises for the permission to take it. Now, as a considerable portion of the capital created by the companies was expended in these compensations and bribes, and no actual value was received for the concession—in other words, as much of the stock was virtually fictitious, it became the immediate interest of the companies to oppose any scheme which seemed likely to diminish the existing profit by competition. It was the interest of landowners to encourage such rivalry, and it was very plausibly alleged that as the parliamentary sanction had been obtained at the company's cost and represented a large sum in the company's liabilities, it should be defended and protected against the aggression of rival schemes. It has thus come to pass, that the principle of protection has been to a large extent recognised in railway undertakings, and every session large sums have been expended by the companies in defence of privileges which seem to be just, because they have been largely and fully paid for. Had the market value been given for land at the outset, and compensations been accorded for real injury only, subject, in case of provable benefit hereafter, to a corresponding reduction, the whole system of parliamentary attack and defence would have been exploded as irrational, unjust, and contrary in the fullest sense to public policy.

Nor is this all that railways have been liable to. After the great lines had been constructed, the system of branches was begun, and a different set of tactics was employed. It was found out that a railway was a benefit, but the shareholders of the old companies knew that the construction of these small lines would be an inevitable loss. They were constrained to make them, or imagined that they were constrained to make them, or purchased them when constructed on very advantageous terms to their temporary and sagacious owners. The writer was informed some time since, when enquiring of a leading director in one of the greatest English railways, that in no case had the company failed to suffer a serious loss by these transactions, and that had they seen a way of escape, they would never have entered into these negotiations. The whole of this loss is the fruit of the parliamentary system of railway enterprise, and of the waste of capital consequent on the incidents of that system.

When railways were constructed, parliament sanctioned a vast number. The old map in *Bradshaw's Guide* contained for some time projected railways as well as those which were constructed or in course of construction. It is hardly necessary to say that such a sanction, on the understanding that government was competent to decide upon the powers possessed by the company, was the ridiculous misconception of the amount of capital available for these works. The annual savings of the country are reckoned at seventy millions—a sanction was given for an outlay of six times this amount in a single year.

The Acts under which railways are governed generally provide that when the profit exceeds ten per cent. the excess should be accumulated, or fares should be reduced, or some public use should be made directly or indirectly of the surplus. Government has also reserved to itself the right of purchasing railways; and as means of public transit, assumes, properly enough, a right of action with them in public emergencies. But the causes noticed above have put out of sight the possibility of the government maxi-

mum rate of profit. The interest on the aggregate of railway stock is, and probably always will be, rather lower than the dividends on consols, the fares and rates being notwithstanding higher than in any country, though they should have been under a sounder system much lower. For information on the early history of English railways, see Mr. Francis *On Railways*.

The estimate of the average cost of conveying a train a mile is as follows:—

	s.	d.
Maintenance of way and works	0	5½
Locomotive power	0	9
Repairs and renewals of carriages and waggons	0	2¼
General traffic charges	0	9
Rates and taxes	0	1¼
Government duty	0	1
Compensation for personal injury, and damage and loss of goods	0	0½
Legal and parliamentary expenses	0	0½
Miscellaneous working expenditure not included in the above	0	2
	2	7

On the hypothesis that a train conveys 25 carriages, all of which are full, it follows that each passenger can be conveyed 100 miles at an average cost of something less than threepence farthing. The lowering of fares, reduced sometimes under circumstances of rivalry and competition to one-eighth of the ordinary charges, has not been found to cause a loss of more than *half per cent.* in the dividends.

These remarks apply with equal force to the carriage of goods. It has been shown that coals can be bought at the pit's mouth in some districts and conveyed to London at a total cost of seven or eight shillings a ton; but under the existing system the price paid for each ton on reaching its destination is quadrupled. A bill was recently sought for by the Great Eastern Company, who proved that the easiness of the gradients on the proposed line would so lessen the cost of construction and the expenses of working as to enable them to bring coals to London in any quantity at a shilling a ton. The bill was rejected on the very ground of this anticipated ability of carrying coals in trains of 400 tons load, profitably, at the rate of one farthing per ton per mile, the chairman remarking that it was not fair to other companies that they should be able to work at so low a rate.

On the other hand, the raising of fares is generally followed by a diminution in the returns. The receipts per train at a penny fare from Shrewsbury to Upton Magna were, in December 1858, 11*l.* 15*s.* 8*d.*; but on the return to a fare of threepence halfpenny in November 1859, the receipts per train fell to 4*l.* 4*s.* 11*d.*

For further details on this subject, and for the arguments in favour of converting the railways into government or national property, the reader is referred to an article on 'Railway Reform' in the *Westminster Review*, April 1866.

Railroads or **Railways.** Roads constructed of tracks of iron called *rails*, on which roll the wheels of carriages drawn either by horses or by steam engines, and to which they are confined by ledges or *flanges* raised on the tires of the wheels.

Theory of Railways.—The object to be attained by the construction of roads of every kind is to effect the transport of loads by the least possible expenditure of tractive force; and one road is better or worse than another, cæteris paribus, according as the same moving power is capable of drawing upon it a greater or less amount of load, or a given load at a greater or less speed. Since the moving power, whatever it may be, is expended in overcoming the resistance which the carriages on which the load is borne offer, this object can be attainable only by the adoption of such expedients as will permanently diminish the amount of that resistance; and common roads, canals, and railways, which are all expedients for diminishing the resistance of traction, have each their appropriate sphere. Common roads are suited for moderate amounts of traffic, and for the miscellaneous purposes of domestic communication. Canals are best for carrying cheap and heavy articles at a low speed; and railways are proper where there is a large traffic, and where a high rate of speed is required.

History of Railways.—About the middle of the seventeenth century, the transport of coals from the pits to the harbour was effected in the coal districts of Northumberland and Durham by laying down parallel tracks of timber with a horse path between them, the wheels being confined upon the beams or rails of timber by ledges or flanges projecting from the inside of the tire of the wheels. These timber rails were constructed in pieces of about 6 feet long with a section of about 4 inches square; they were supported on pieces of timber called *sleepers* laid at right angles to them transversely on the road. These sleepers were laid at about two feet apart, so that each pair of parallel rails was supported by three sleepers. Besides giving support to the rails, these sleepers had also the effect of maintaining the rails in gauge, or in keeping them at a fixed distance asunder. The rails were fastened to the sleepers by pins driven quite through the rails, and half-way through the sleepers. To preserve the uniformity of the upper surface of the rail, these wooden pins were planed off at the top.

The necessity of giving room for the flanges of the wheels, running as they did below the surface of the rail, and the small depth between the surface of the rail and the sleeper, rendered it impossible to protect the sleepers effectually from the action of the horses' feet by any covering of gravel or other material. The sleepers were consequently subject to great wear and tear. The rails also, being worn by the action of the wheels still more rapidly than the sleepers, required to be frequently replaced; and as each new rail was pinned down

to the same sleeper, the ends of the sleepers were gradually perforated by so many holes that the sleepers were weakened and required to be soon replaced. These defects were remedied by the adoption of the double-timber railway, which consisted in laying upon the surface of the timber rails, above described, additional rails of timber of equal scantling, attached to the lower rails by wooden pins, passing quite through the upper and half through the lower rails, in the same manner as the lower rails themselves were attached to the transverse sleepers. This change was attended with many advantages. Besides the increased strength given to the rails by the double timbers, the depth of the sleepers below the upper surface of the superior rail allowed the sleepers to be protected from the action of the horses' feet by covering them with broken stones, gravel, or other road materials. The structure of rails and sleepers also being stronger and more weighty, and held down by the road material with which the sleepers were covered, allowed a packing or ballasting to be driven under the rails, so as to give greater stability and firmness to the road. Another advantage obtained by this arrangement was, that when the superior rails were worn by the action of the wheels, they could be replaced by new ones without disturbing the inferior rails; and as the places of the joints, and those at which they were attached by pins to the inferior rails, could be varied at pleasure, the pin-holes made in the inferior rails would not come in the same place, or near each other, so as injuriously to weaken the latter.

The next improvement consisted in the addition of a plate or bar of iron, about two inches broad and half an inch thick, laid along the upper surface of the superior rail, and attached to it by nails or iron pins countersunk in it. The wheels of the carriages ran upon this iron rail, which formed a more durable surface than that of the wood. In the United States of America, railways of this construction are still in occasional use. They are recommended in that country by the abundance and cheapness of timber and the comparative high cost of iron. Such a road is tolerably efficient where the traffic is light and slow, and can therefore be resorted to in localities and circumstances in which an adequate return could not be obtained for the capital necessary for the construction of the more perfect modern railway. In the construction of these timber railways in America many other improvements have been introduced, more especially in the substructure of the road. In laying out the roadway for the reception of the rails, two parallel trenches are cut along the line of way corresponding to the distance between the rails, and transverse trenches at right angles to these are cut to receive the sleepers: these trenches are respectively bottomed with a ballasting of broken stone, on which the rails and cross sleepers rest. This basis answers the double purpose of a firm and durable support for the road and an effectual means of drainage. The scantling of the timbers used for the rails is usually six inches in width by ten inches in depth: they are attached to the sleepers, so as to be at once kept from springing from them and from altering their gauge, by the following means: A notch is cut in the sleeper corresponding to the size and form of the rail, and the rail, at the place where it is let into the sleeper, is formed with a vertical surface on the outside, and a levelled surface on the inside, increasing in width downwards. When let into the notch of the sleeper, the levelled part of the rail is forced into the corresponding cavity of the notch by a wedge driven between the outside edge of the rail and the outer surface of the notch.

The Plate Railway or Tramway.—In the progress of improvement, the timber railway above described was succeeded by the iron-plate railway, or tramway, in which the wheels —which were without flanges—ran on cast-iron plates formed with a ledge on the outer edge of each track to prevent the wheels from running off; and this species of road was for a long period almost exclusively used in the coal districts, and in public works generally, and is still employed to a considerable extent, especially in the railways which are carried through the workings of mines, and on which the produce of the mine is conducted in waggons, being pushed by men or drawn by horses to the foot of the shaft.

These tramways were for a long period constructed exclusively of cast iron; but, when improved methods of rolling malleable iron were contrived, they were formed by rolling.

Edge Railways.—Within twenty years after the first introduction of tramways of iron, the form of rail called the *edge rail* was brought into use. This rail is constructed in the form of a bar of iron, the width of which is considerably less than its depth, placed, as the name implies, with its narrow edge presented upwards. Owing to its depth being much greater than its width, its power, in proportion to its weight, to resist vertical pressure is very considerable. The wheels are retained on rails of this description by flanges projecting from the inside of their tires. These flanges, at the point where the wheels rest on the rails, descend below the rails; and the wheel cannot pass off the rail towards the outer side, unless the flange rolls over the rail.

For a long period after their first adoption, edge railways were confined to the mining districts, and more particularly to the collieries, where they were used for the transport of the products of the mines to the places of shipment; but this species of road acquired vastly increased importance when passengers and goods came to be transported on it by locomotive engines, which took place first on the Stockton and Darlington Railway in 1825, but more prominently between Liverpool and Manchester in the year 1830. Since that time, the construction of railways adapted for general traffic,

at a speed which would have been formerly thought impossible, has been carried to a great extent in all parts of the world.

Statistics of Railways.—It is now almost useless to collect the statistics of railroads, because in most countries the figures which are correct this day may be totally unfit to give the relative number of lines, and their lengths opened, a few months hence. Thus the Indian railways opened in May 1865 extended to a length of 3,186 miles, but it was calculated that they would extend at the end of that year to 4,917 miles. The following table, extracted from Perdonnet's *Traité Élémentaire des Chemins de Fer*, ed. 1866, will enable the reader to form some idea of the degree in which the various nations of Europe have availed themselves of the new means of locomotion.

Country	Length in Kilomètres opened	Length in Kilomètres granted	Length per Myriamètre square opened	Length per Myriamètre square granted	Length per Million of Inhabitants opened	Length per Million of Inhabitants granted

Within the limits of the present article, it would not be possible to trace, in the order of time, the succession of improvements by which the present methods of laying out and constructing railways for the swift transport of passengers by steam power have been established. When the Liverpool and Manchester line was first brought into operation, little, comparatively, was understood of the capabilities of such means of intercommunication; and that line may be regarded as an experimental railway, the results of which have supplied the data on which others have since been constructed and worked. The form, strength, and weight of the rails; the mode of fixing them on the road; the weight, power, and proportions of the engines; the form, strength, and weight of the carriages and waggons; the magnitudes of the trains, and the speed of transport, have all been subject to change from year to year, and almost from month to month, since the opening of that line in 1830 to the present time. We shall not, therefore, attempt to trace these improvements; but shall briefly explain the formation and construction of railways, according to the methods and principles at present generally received.

Gauge of Railways.—The gauge, or the distance between the rails, on which depends the distance between the wheels of the carriages and engines, and to a certain extent their structure, has frequently been a subject of much discussion. It is now generally admitted that all railways constructed in the same country ought to have the same gauge; and though it is not contended that the gauge now in use is the best that could possibly have been adopted, yet that, extensive lines of road having been constructed with that gauge, the disadvantages attending a departure from it will be greater than any counterbalancing advantages that could attend any other magnitude of gauge.

In the colliery railways in the north of England, the rails had been laid at 4 feet 8½ inches asunder; and on the Liverpool and Manchester Railway, the first line intended for general traffic was laid down by Mr. Stephenson with the same gauge. The lines of railway subsequently projected, extending from Liverpool and Manchester to Birmingham (and thence to London), to Preston, Wigan, Bolton, Leeds, and other places, were laid down with the same gauge, since the carriages and engines would necessarily have to pass from one to the other. But when railways began to be constructed in Belgium and other parts of the Continent, where the same reason for uniformity of gauge did not prevail, the same gauge nevertheless was adopted. The first conspicuous departure from this uniformity took place on the Great Western Railway, extending from London to Bristol, which was laid down with a gauge of 7 feet; and the Eastern Counties Railway next adopted a gauge of 5 feet. The latter line (now known as the Great Eastern) has since been reduced to the 4 feet 8½ gauge, and the same gauge has been laid down (in addition to the 7 feet gauge) on a considerable part of the Great Western system.

The gauge of a railway can be regarded as nothing more than its linear modulus, or the index to its general scale. There is nothing per se to give one gauge a preference over another; but, as the magnitude of the gauge determines the general magnitude and scale of the railway, and of everything connected with the railway, including waggons, carriages, and engines, bridges, viaducts, tunnels, cuttings, &c., and, in short, all the works, whether of a movable and perishable or fixed and permanent nature, it is a matter of the greatest

importance that it should be determined with a just regard to the traffic of the line.

The *battle of the gauges* may be explained on this ground, for there can be no doubt that the 4 ft. 8½ in. gauge was adopted by accident; but when once adopted, it was found to be more convenient to execute the rest of the railway system of the same dimensions. The facility afforded for intercommunication upon the uniform gauge, the economy resulting from the small gauge (which is a great element in the commercial results attending a railway), the greater ease of working, all give the narrow gauge advantages not compensated for by any perceptible amount of speed or convenience in travelling upon the broad gauge. The reader is referred, for an account of the struggle that took place on the subject of the gauges, to the pamphlet by Wyndham Harding on the question; to the *Report of the Gauge Commissioners*; to the *Life of Robert Stephenson*, vol. ii. ch. i., by Professor Pole, in which the arguments for and against the broad and narrow gauges are carefully stated. The result of the argument has shown that it is not worth while, particularly in a poor district, or in districts which do not contain the elements of an active circulation, to incur the expense of the broad gauge; and as the traffic of the lines of every country is destined, sooner or later, to intercommunicate in every direction, any break of gauge must always be attended with a considerable amount of inconvenience. Practically, the broad gauge has been abandoned, or at least the mixed gauge has been laid down on almost every line on which the broad gauge had been established.

Of the Formation and Construction of Railways.—Whatever be the moving power to be used for the transport of loads upon a railway, its force should be proportioned to the maximum resistance of such loads, and it should be capable of varying its energy to the same extent as that resistance is subject to variation. The great perfection which has been attained in the construction of the rails, and in the methods of fixing them in their position upon the road, is such, that the resistance offered to the tractive power by loads moved on a straight and level railway may be regarded as practically uniform, so that the moving power by which a load is transported at a given speed on a straight and level line of railway is subject to a resistance as unvaried and as uniform as any to which moving powers are usually submitted in any of the processes of art. But as the amount of resistance to the tractive power upon a straight and level railway is diminished by the perfection thus attained in the construction of the road, so, in the same degree, any resistance produced by a departure from a perfect level is more sensibly felt. Thus, if the resistance to the moving power on a straight and level railway, by a load moved at a given speed, be equal to the 250th part of the load, an acclivity which would rise at the rate of one foot in 250, or nearly at the rate of 20 perpendicular feet in a mile, would produce a resistance to the moving power, by reason of the ascent alone, equal to a 250th part of the load, and therefore equal to the resistance which the moving power would sustain on a level line. It follows, therefore, that, under such circumstances, in drawing a load up such an acclivity, the moving power would have to overcome twice the resistance opposed to it on a level; for the same causes which produce on a level a resistance amounting to the 250th part of the load also produce the same resistance in ascending the acclivity, in addition to which there would be an equal amount of resistance due to the ascent. If, therefore, under such circumstances, the moving power were required to draw the load up the acclivity at the same speed as that at which it drew it on the level, the machine exerting that power must be endowed with properties in virtue of which it becomes capable of varying its energy, without injury to its structure, in the proportion of two to one.

The power now employed almost universally to draw carriages upon railways is the locomotive engine, some of the wheels of which are rotated by being put into communication with the steam cylinders, and the friction of these wheels on the rails propels the train.

The tires of the locomotive wheels, and of the wheels of all the carriages, have usually a conical form given to them, becoming gradually smaller from the flange outwards; and, when a carriage rests straight upon the rails, the distance between the flanges of the wheels being less than the distance between the rails, a small space is left between the flanges and the rails, to allow some play to the flanges without letting them strike the rails. When the carriage comes to a curve, the flange of the outer wheel comes into contact with the outer rail, and the whole play of the flanges is given to the space between the flange of the inner wheel and the inner rail. In consequence of the conical form of the tires of the wheels, the outer wheels, in this case, rest upon a thicker part of the cone than the inner, and the actual diameter on which they revolve is consequently greater than that on which the inner wheels revolve. This effect has been generally regarded as an expedient sufficient to enable railway carriages to run round curves of a certain limited radius; but in some of the large continental locomotives other expedients are sometimes employed.

The pressure of the flange on the rail being the principal means of turning a railway carriage round a curve, and such pressure being attended by friction, and therefore by increased resistance to the moving power, curves as well as acclivities are a cause of resistance, and this resistance will be great in proportion to the rapidity of the curve or the shortness of its radius. But independently of this effect of curves, a more serious objection to curves of which the radius is under a certain limit of magnitude arises from the liability of the carriages to run off, by the flange encountering

any obstacle or inequality which would cause it to pass over the rails. This tendency is increased if there be a declivity as well as a curve, and if at the same time the train is travelling at a high rate of speed.

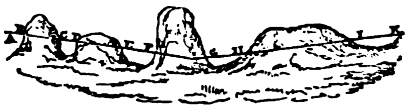
Curves on Railways.—With a view to insure the public safety, the legislature has generally required that no curve shall be allowed upon a main line with a less radius than one mile: the exceptions to this are where one railway passes into another, and at the termini, or the entrance of dépôts or stations. In such situations the trains must slacken their speed, and therefore a sharp curve is attended with less danger. It has appeared, however, that these restrictions upon the radii of curves have been more stringent than safety requires. In a course of experiments made by Dr. Lardner, it was established that curves of a mile radius produce no sensible increase of resistance at the usual speed of railway trains, and therefore curves of considerably less radius may be traversed at that speed without danger. We may here state, that on the Newcastle and Carlisle Railway there are many curves in the main line with radii under half a mile, which are traversed at the usual speed with perfect safety.

The *section* of a railway is limited by those circumstances which govern its acclivities, already explained, and which are equally related to the amount of resistance on level rails, and to the practical limits of the variation of the moving power. The *plan*, on the other hand, is limited by the necessity of effecting every change of direction of the line by curves of which the radius shall have such a magnitude as to exclude all danger of the carriages running off the line. In the laying out of a railway, therefore, limitations of its section and plan must be kept constantly in view.

Since the natural surface of a country is rarely adapted to the conditions which have been thus shown to be necessary to the formation of a railway, an artificial surface must generally be formed by raising some and lowering other parts of the country through which the railway is to pass. The expedients by which this is accomplished are attended with more or less difficulty and expense, and the skill of the engineer is eminently required in the selection of such a course for a proposed line of railway as will be attended with the least expensive construction, due regard being had to the permanent expense of working and maintaining it.

When a railway is proposed to be constructed between two points, which are called its *termini*, the engineer makes himself generally acquainted with the country between these termini, and selects that course for the line which, with least deviation from a straight line joining the proposed termini, will afford the greatest facilities for the formation of the artificial surface of the railway, limited as it must be in respect to its acclivities, and to the curves by which its various changes of direction are effected. This is first accomplished by an *eye survey* or general *reconnaissance* of the country. An instrumental survey is afterwards made along the direction which has been selected for the line, and a nearly accurate profile of the country from terminus to terminus, in the proposed direction, is obtained. This being accomplished and reduced to a drawing, as represented in fig. 1, a line A B C D E F G H I K is drawn, regulated by the degrees of inclination which have been decided to be the best practical limits of the acclivities. This line will, as

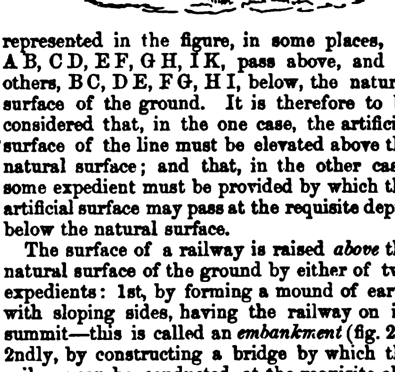
Fig. 1.



represented in the figure, in some places, as A B, C D, E F, G H, I K, pass above, and in others, B C, D E, F G, H I, below, the natural surface of the ground. It is therefore to be considered that, in the one case, the artificial surface of the line must be elevated above the natural surface; and that, in the other case, some expedient must be provided by which the artificial surface may pass at the requisite depth below the natural surface.

The surface of a railway is raised *above* the natural surface of the ground by either of two expedients: 1st, by forming a mound of earth with sloping sides, having the railway on its summit—this is called an *embankment* (fig. 2); 2ndly, by constructing a bridge by which the railway can be conducted, at the requisite elevation, above the natural surface of the ground in the same manner as a road is constructed over a river—such a bridge is called a *viaduct*. [VIADUCT.] Such structures are formed either

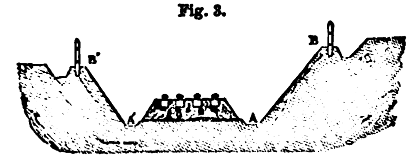
Fig. 2.



of masonry or of iron; but in countries such as the United States and Russia, where timber is abundant, cheap viaducts of carpentry are frequently used.

The surface of a railway is conducted *below* the natural surface of the ground by either of two expedients: 1st, by forming an excavation,

Fig. 3.



or artificial valley, with sloping sides, along the bottom of which the railway is constructed

—such an excavation is called a *cutting* (fig. 3); 2ndly, by undermining the ground and constructing a subterranean archway or vault of sufficient magnitude, the roof of which is usually lined with masonry, and along the bottom of which the railway is conducted—such an archway is called a *tunnel*. [TUNNEL.]

In laying out a railway, the disposition of its cuttings and embankments must be kept in view. In general, the material by which the embankments are formed is obtained from the cuttings; and, with a view to the saving of expense, the engineer so arranges his section that the quantity of stuff required for the formation of embankments shall be as nearly as possible equal to that supplied by the cuttings. If there be an excess of stuff from the cuttings, ground must be obtained in some position near the cuttings whereon it can be thrown. This is technically called *putting it to spoil.*

If, on the other hand, there be an excess of embankment, then the stuff necessary for the formation of such embankment must be obtained from some excavation made near the embankment expressly to supply the stuff for the embankment. This is called *side cutting.*

The distance along which the stuff obtained from a cutting is carried before it is laid down to form the embankment is called *the lead*; and the quantity of labour necessary to form an embankment out of an adjacent cutting is determined by the number of cubic yards of stuff necessary to form the embankment multiplied by the average *lead*, or the mean distance to which such stuff has to be carried.

Where a very low and long embankment occurs, it may happen that the *lead* is so long that the expense of forming the embankment from the nearest cutting would be greater than the expense of putting the cutting *to spoil*, and of forming the embankment from *side cutting*. These are questions which are determined in each individual case with reference to the price of land and labour.

When the elevation above the natural surface of the ground at which the railway must be carried is so great as to render an embankment impracticable, or attended with a disproportionate expense, a viaduct is resorted to; and, on the other hand, when the excavation necessary to give an open cutting would be productive of objectionable expense, then the railway is conducted under the ground through a tunnel.

The slopes A B, A′ B′, figs. 2, 3, forming the sides of embankments and cuttings, depend on the nature of the soil or strata through which the cuttings are made, and of which the embankments are formed. In general, every material has a certain angle at which it will rest, all more steep angles causing it to slip or fall; this angle is called, in mechanics, the *angle of repose*. In the strata through which railway cuttings are made, and from which embankments are usually formed, the slopes of the sides are rarely less than 1½ foot horizontal to 1 foot vertical, and they vary between that and 2 feet horizontal to one foot vertical. When the material is gravel, sand, loose chalk, or gravelly clay, a slope of 1½ to 1 is generally found sufficient; but with certain descriptions of clay, such as that called the London clay, a more gradual slope must be allowed. With such material, the slopes are constructed at 1½ or 2 horizontal to 1 vertical; but in general it is better, even at increased expense of earthwork, to allow a sufficient slope in the commencement, and thereby avoid the continual expense attending *slips*, as the gradual decadence of the sides of cuttings and embankments is called.

The face of slopes, both of cuttings and embankments, should be covered with soil and sown with grass seeds, so as to produce a turf, which gives a further security against *slips*. They may be also, especially the slopes of embankments, planted with shrubs; care being taken, however, not to obstruct the ventilation of the road.

When the stratum through which a cutting is required to be made is rock or hard stratified chalk, it will stand with perpendicular sides; and, in such cases, cuttings of great depths may be made at a trifling sacrifice of land. The Olive Mount cutting on the Liverpool and Manchester Railway is, at the deepest parts, above 100 perpendicular feet from the natural level of the surface to the level of the rails; and cuttings of still greater depth and much greater extent, through stratified chalk, are executed on the Brighton Railway, of which the sides are perpendicular.

In most cases, however, where cuttings attain to these extraordinary depths, tunnels would be less expensive. It sometimes happens that the material of the cutting is required for an adjacent embankment; and, under such circumstances, if the sides of the cutting can be perpendicular, and the sacrifice of land small, it may be preferable to tunnelling. The materials from the Olive Mount cutting above mentioned were required for the formation of the Broad Green embankment adjacent to it.

The physical peculiarities of the ground over which many of our railways have been carried, have caused formidable difficulties in their construction. Chat Moss, on the Liverpool and Manchester line, was 4½ miles across when the railway was carried over it, and from 20 to 40 feet deep. Cattle could not stand upon it, and a piece of iron would sink into it by its mere weight. To form an embankment of 277,000 yards, 670,000 yards of material had to be thrown into the bog. In the Haslington cutting, on the East Lancashire line, half a million yards of peat, sand, and gravel, had to be excavated from a bog hole, and two trains carrying earth for three months were unable to obtain a foundation. Large stones were finally thrown in, which pressed the peat aside, and enabled the line to be carried across. The Ogden viaduct, which is carried over a quicksand 50 feet deep, required 1,500 cubic yards of earthwork to

be thrown in daily for many weeks to obtain a foundation. At Ashton, where a fifty-feet embankment had to be raised, the ground sank with the weight of the earth, which disappeared as fast as it was deposited, and at length the surface of the surrounding fields burst upward with the pressure. On the Leeds and Bradford, Durham and Sunderland, Midland and many other railways, the line has been carried over bogs and swamps, by which large quantities of material were swallowed up before any visible progress could be made. At the Ambergate cutting the occurrence of a seam of shale, rising at an acclivity of 6 to 1, caused the whole side of a hill to slip down, and involved the necessity of removing 500,000 yards of earth. Then in carrying tunnels through some hills the quantity of water to be pumped out presents a serious impediment. In forming the Box tunnel on the Great Western line, 32,000 hogsheads of water had to be raised daily for many months. In the Kilsby tunnel, on the North-Western line, 2,000 gallons of water had to be raised per minute for eight months. In forming the Woodhead tunnel of the Sheffield and Manchester line, eight million tons of water were raised in five years. On the Dundalk and Enniskillen line, an embankment twenty feet high sank in a concealed bog and stopped a river, the country being flooded in consequence. Sometimes embankments have been made of fuller's earth, which melts down with the rain. The introduction of iron pyrites has sometimes caused embankments to give forth smoke and flame, and to burn the sleepers; and if pyrites come into contact with chalk, crystals of selenite are formed, which disintegrate the clay, alter its bulk, and render it treacherous. These facts illustrate the importance of a minute examination of the ground over which any line of railway has to be carried, in order that such sources of expense and failure may as far as possible be avoided.

The quantity of earthwork per mile of railway varies, of course, very much upon different lines; but taking upwards of 8,000 miles of English railway, Mr. Robert Stephenson estimated that the average earthwork per mile was 68,300 cubic yards. On the London and Birmingham, London and South-Western, London and Brighton, and North Midland, it is more than twice this amount. The London and Birmingham line had 12,081,116 yards of excavation, and 10,698,315 yards of embankment in the original estimate, or together 202,934 cubic yards per mile. The heaviest cutting on the line is at Tring, which is 2½ miles long, and averages 40 feet deep. The New Cross cutting of the South-Eastern line is two miles long, and for some distance is from 75 to 80 feet deep. The Box cutting of the Great Western Railway is 2½ miles long, and averages 30 feet deep. The Brentwood cutting of the Great Eastern Railway is upwards of a mile long, and 60 feet deep; and the Olive Mount cutting on the Liverpool and Manchester Railway is two miles long, and 100 feet deep. Nearly all the English lines are formed with a double track, and with a gauge of 4 feet 8½ inches between the inner edges of the rails, the Great Western alone and its branches being formed with a gauge of 7 feet, but on a large part of this line a third rail has now been laid down to enable narrow-gauge engines and carriages to travel over it.

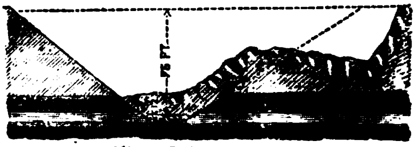
In English railways the standard width of the *formation level*, as it is termed, or the width of the ground between the ditches, is 32 feet, and the ditches are each 3 feet wide at top, 1 foot wide at bottom, and 1 foot deep. The width of the ballast at the top is 23 feet 5 inches, and at the bottom 27 feet 5 inches, and it is 2 feet thick. The wooden cross sleepers embedded in it are 9 feet long. On the outside of each ditch there is a breadth or terrace of 18 inches wide; and if the railway is in a cutting, the bottom of the slope springs from the outer edge of the terrace, rising at a slope of 2 to 1, so that the total width of the bottom of the cutting is 41 feet. In the French railways the dimensions are nearly but not quite the same. The width of the formation level is 30 feet 10 inches, and the ditches are each 4 feet 11 inches wide at the top, 19⅝ inches wide at the bottom, and 19⅝ inches deep. The breadth of the shelf or terrace at the outer side of each ditch is 19⅝ inches or 50 centimètres, and the total width of the bottom of the cutting is 43 feet 11½ inches. The width of the track, measuring from the centre of each rail, is 150 centimètres or 59 inches, and the width of the ballast at bottom is 27 feet 6¾ inches; at top, 22 feet 11½ inches; and the thickness of the ballast 19⅝ inches. The sleepers are a little shorter than on the English lines. The side drains on all lines are made much broader and deeper than the foregoing in certain cases, where large volumes of water have to be carried off.

Drainage.—One of the conditions most powerfully affecting the security, durability, and efficiency of a railway is the efficiency of its drainage. The history of all failures in earthworks shows that in almost all cases they arise from unskilful or inadequate drainage; and the expense of maintenance on every line will, other things being the same, vary very nearly in the proportion in which its drainage is good or otherwise. Drainage may be divided into two main parts; drainage of the roadway and drainage of the slopes. Water lying or running on the surface soaks and softens the roadway, washes away the earth, and chokes the ditches. The roadway, when thus saturated with water, loses its firmness, and the ballast sinks and disarranges the track, adding seriously to the jolting of the train, to the power necessary to propel it, and to the wear and tear both of the train and track. Clay is converted by water into mud, and swells in bulk; and when it is afterwards

dried by the sun it forms cracks which give ready entrance to subsequent rain, and increase the disintegration caused by frost. The subsidence of the ballast from the ends of the sleepers so induced leaves the rails without uniform and regular support, and the rails are thus strained, the fastenings and chairs broken, and the deflection of the rails, causing the locomotive to be constantly going uphill, sensibly increases the consumption of fuel. The expense incident to the constant rectification of these evils is much greater than that which would be necessary to drain the line thoroughly at once; and it is a primary condition in the execution of all railways upon which rain ever falls, that they shall be thoroughly drained. The surface drainage must provide for the immediate removal of water falling upon the earthwork and slopes at a depth of at least three feet from the surface of the rails, and the drains on slopes must be formed with such a gradual declivity as to prevent the velocity of the running water from tearing up the soil. The side drains in some places are widened from three to thirteen feet and deepened to six feet, and the ditches should be cut as straight as possible, and equally distant from the roadway in all parts. Care should also be taken that the ditches shall empty themselves, and not become receptacles for stagnant water. Culverts are circular or barrel drains built of brick or stone across the railway at a sufficient depth to afford communication between the ditches. They are built with cement, which is allowed to be well consolidated before they are covered in. On the London and North-Western Railway, cross underground drains, of circular perforated tiles, are used. In cuttings the track generally slopes to each end, both to diminish the quantity of cutting and to give free outlet for the water, and if the slope is steep, the side ditches are usually lined with brick or stone. In some of the deep chalk cuttings, the side drains are formed of large bricks, and run the whole length of the cutting underground, with cesspools at convenient distances. These underground drains are often made of semicircular tiles, perforated and resting on flat tiles twelve inches square. In wet cuttings and in tunnels, covered longitudinal drains are made along the middle of the line. Some of these drains are oval, of three feet vertical diameter and two feet horizontal, and the bottom of the drain is set from four to five feet below the surface of the ballast. In the Blisworth cutting the covered drain is an arch thirty inches deep and twenty-one inches wide at the springing, and the bottom is thirty-nine inches below the surface of the ballast. In railway works as well as in agriculture, experience shows that sub-drainage is both cheaper and more efficient than the system of open ditches, as a covered drain sunk three feet below the surface will carry off more water than an open ditch of ten times the capacity. The importance of thorough drainage is shown by the fact, known to every engineer, that the wear and disarrangement of track is found to be from one-fourth to one-half less on moderately high embankments than it is in cuttings; this difference being wholly caused by the more effectual drainage realised in one case than in the other.

The drainage of the slopes is as important as the drainage of the roadway, since, unless such drainage is effectual, formidable slips will certainly occur in many kinds of soil, and the cutting may be choked up in consequence. Fig. 4 represents a slip which took place some years ago on the London and Brighton Railway. The original slope was two to one, and the depth of the cutting was from seventy-five to eighty feet. The upper clay abounded with soapy earths and mineral salts, which rendered it very pervious to water; and becoming completely saturated by the rain which fell in a wet season,

Fig. 4.

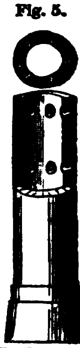


Slip on Brighton Railway.

it slipped forward on a more compact clay below and buried the rails to a depth of twelve feet. The line was stopped in consequence for three months, for not only had the fallen earth to be removed, but the sides of the cutting had to be cut back into benches, two on the one side and three on the other, these benches being in some places sixty-five feet wide, and the intervening slope was made two to one. In all, 250,000 cubic yards of earth had to be removed.

The method most generally adopted for preventing slips in treacherous ground consists in the excavation of vertical trenches at regular distances along the face of the slope and filling the excavation up with counterforts of gravel, for which footings are cut in the solid earth below. These counterforts, by their weight, friction, and porosity, are found to be effectual in preventing slips from taking place. Another method consists in sinking wells in the upper ground, so as to intercept the water before it reaches the face of the slope; while a third method, first recommended in the *Artizan* in 1843, and since carried out on some of the French lines, consists in cutting a vertical trench or drain from the top of the slope to the level of the rails beneath, and filling it with stones to constitute a drain from which the water may be led off to any convenient outlet. This mode is expensive. But another mode, also propounded in the *Artizan*, would be equally effectual and would cost less. It consists in cutting horizontal trenches of moderate depth along the face of the slope, the bottom of each of which would come at least as low as the top of the trench next

Fig. 5.



Perforated Drain Pipe.

beneath. These different trenches are to be filled with stone, and are to communicate at intervals with one another, so as in effect to constitute a drain extending through the whole depth of the embankment. Large slips are promoted by frost, which seals up the face of the cutting and causes the water to accumulate behind until its hydrostatic pressure forces out the face of the cutting. Probably a combination of the horizontal drains in steps, with vertical counterforts of gravel at some distance apart to connect the drains together, is the cheapest and most eligible expedient for draining the slopes of heavy cuttings. In cases where the amount of drainage to be accomplished is not great, the introduction of perforated tile pipes of the form shown in fig. 5 will probably suffice.

Ballast.—The ballast of a railway consists of porous materials laid on the surface of the ground in which the sleepers are embedded. These materials are either broken stone, gravel, burnt clay, cinders, sand, broken bricks, or small coal; but of these gravel with a natural mixture of clean sand is the best. The ballast, besides securing the sleepers and rails in their place, promotes by its porosity the thorough drainage of the line, resists the sinking of the sleepers, and enables them to be readily packed up, while it gives a proper amount of elasticity to the road, which is more conducive to durability than the plasticity of earth or the rigidity of rock. Very hard materials do not act well as ballast. Broken trap-rock becomes consolidated, by packing, into so inelastic a mass that the rails are soon battered out. When broken stone is employed as ballast, the pieces should go through a 2½-inch ring. Limestone binds too much for ballast, but gneiss rock and even sandstone answer very well. Slate is rapidly disintegrated in wet weather. Gravel, if too fine, will not drain well, and if too coarse, will not pack well. Burnt clay is used in alluvial districts where gravel is not to be had, and has been widely employed in the Indian railways. A ton of small coal will burn from 20 to 25 cubic yards of clay; and where coal or wood is cheap, this kind of ballast is as cheap as gravel if the latter has to be brought 6 or 8 miles. Of the 2 feet of thickness of ballast used on English lines, 1 foot is below the sleeper and 1 foot around and above it. Although on the French lines the standard depth of the ballast is 50 centimètres, the thickness is made 10 centimètres more, or 23½ inches in situations where the soil is bad. In America the railways are in general very imperfectly ballasted, and the cost of maintaining them is consequently very great. The expense of maintenance per mile run of the great English railways is found to be only about one-fourth of that of the great American lines; and if the latter could be made to work with equal economy, the saving, it is computed, would add 1·8 per cent. to the dividend. It is mainly in the difference in the earthworks, drainage, and ballasting, that the great difference in the cost of maintenance is to be found.

Sleepers.—In most of the English and foreign lines the rails rest in cast-iron chairs, which are spiked to cross sleepers of wood; but in the Great Western and a few other lines the rails rest upon longitudinal beams of wood, and in the American lines the bottom flange of the rail is for the most part spiked directly down upon the cross sleepers without the intervention of chairs. Stone blocks, which were generally used in the early railways for supporting the chairs, have now been discarded. But sleepers of cast iron have latterly been in many cases employed. These consist either of plates, or inverted pots like dish-covers, with holes on the upper side to permit packing, and connected by tie rods across the railway. In some cases the chair is cast on the top of the sleeper, and in other cases it is bolted on. In some instances rails have been employed formed with a wide and deeply immersed base, with the view of dispensing with sleepers altogether. But this species of railway has not yet attained any great success.

The sleepers commonly used on the English lines are larch trees of about ten inches diameter split through the middle; the flat side is laid upon the ballast, and the chair is fixed upon a flat seat notched out upon the convex side. Oak makes better sleepers than softer woods, but is too expensive for general purposes. It may, however, be put down in sharp curves and in other exceptional situations. The sleepers should be straight and of uniform size. They are usually laid at a distance of 3 feet from centre to centre, which gives about 2½ square feet of bearing surface for each running foot of track. In lines with a heavy traffic the sleepers are pitched at 2½ feet distance, thus giving 3 square feet of bearing for each running foot of track. In the American lines the sleepers are pitched at about the same distance as on the English lines or a little closer. It is found, by experiment, impracticable to use alternate wood sleepers and stone blocks, from the unequal nature of the support. But wooden blocks alternating with wooden sleepers have been tried in France, and have been found to answer well. The beams used on the longitudinal system for the support of the rails are ten inches square, and these beams are connected at every 6 feet by cross pieces of 6 by 4 inches.

The ordinary duration of sleepers laid down in their natural state is seven years. By creasoting their cost is increased about one-fourth, but their durability is more than doubled. Creasoting is accomplished by forcing coal oil into the timber by hydrostatic pressure, the timber being placed in a great cylindrical vessel of wrought or cast iron like a boiler, to enable it to be soaked and penetrated by the preservative liquid. The timber is laid on a truck, and run into this cylinder, from which the air is then exhausted after the movable end of the cylinder has been screwed on. This exhaustion is accomplished by an air pump worked by an engine of six or eight horse power. The preservative liquid is then allowed

to enter, and a vacuum of 27 or 28 inches of mercury is maintained within the cylinder for half an hour, at the end of which time the liquid is forced in with a pressure of 130 lbs. per square inch. The pressure is maintained for six or seven hours, at the end of which time the process is complete. Coal tar contains ammonia, which rots wood, but is expelled by boiling, and the boiled tar is called *coal oil.* This usually contains from 10 to 15 per cent. of creasote. The quantity of creasote present in such oil may be determined by shaking up with it in a bottle about 10 per cent. of a strong caustic alkaline solution; the liquid will settle into three layers, of which the lowest is caustic alkali, the middle creasote, and the upper (which is by much the largest) bituminous oil.

The forms of cast-iron sleeper which have been introduced on different lines are very various. Fig. 6 represents Samuel's cast-iron and timber-cushioned sleeper, which is 42 inches long, 16 inches wide, weighs 132 lbs., and gives a bearing of 672 square inches. De Bergue's cast-iron sleeper consists of a rectangular plate 20 inches by 14 rounded at the corners and strengthened by feathers. It weighs from 46 to 56 lbs. and gives nearly two square feet of bearing. Greaves' spheroidal or pot sleeper is shown in fig. 7. This sleeper has been much used on the Indian lines and also on other lines abroad. The packing is accomplished through holes left near the crown for that purpose. In all these sleepers there are tie rods for connecting them together across the line so as to keep the rails in gauge.

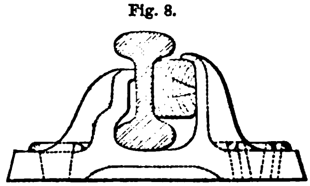
Greaves' Pot Sleeper.

Rails.—In the early railways much attention was paid to the quality of the iron of which the rails were composed; but subsequently this condition was relaxed, and a very inferior quality of iron was for many years admitted. More recently, however, the quality of the iron used in the manufacture of rails has been improved, and steel rails have also been tested, and are likely to obtain a wide introduction. In 1856 rails of 85 to 100 lbs. per yard were considered by English engineers to be the best. But in the succeeding decennium lighter rails, more thoroughly shingled and better worked in the rolling, were found to be preferable. On the Great Eastern line, the 95 lb. rails were found to wear more and make a worse road than the 75 lb. rails, and on the London and North-Western line the 82 lb. rails were found to be worse than the 56 lb. The Grand Junction line, laid with 62 lb. rails in 1837, remained in good order without the necessity of removing any of the rails till 1849, when a few 80 lb. rails were put down, and these showed more wear in twelve months than the old rails exhibited after enduring the traffic of twelve years.

The double-headed form of rail is usually now employed in England and most other countries, one object of this form being to allow the rail, when worn on the top, to be turned upside down. But sometimes the bottom is so much indented by the chair as to prevent this. In this form of rail a chair is required for every sleeper, and the rail is usually fixed in the cast-iron chair by a wooden key driven in at the side, the wood (before being cut into lengths) being compressed by hydrostatic pressure or otherwise to prevent subsequent shrinking. The common depth of rail is five inches. It is found that a 50 lb. rail 3⅝ inches deep and with a 3 feet bearing deflects sufficiently under a fixed load of five tons to be equivalent to a gradient of 25 feet in the mile; and it has further been found that, while gravity has to be overcome by ascending the hills, no return of it is got back in descending the hollows. With a moving load the deflection would be doubled. The deflection of the rails is as the cube of the distance between the supports; and if some of the sleepers sink, the deflection and consequently the resistance of the line will increase at a very rapid rate. This accounts for the great additional tractive power required on rough lines which have fallen into disrepair.

Fig. 8.



Standard English Rail and Chair.

The width of the head of modern rails is about 2½ inches. If the elasticity of the metal be supposed to be such that a sheet of paper could be got only within half an inch of the bearing point of a five-foot driving wheel, the wheel would from this amount of yielding be constantly ascending a gradient of 45 feet per mile. Fig. 8 is a section of a standard English rail and chair, and figs. 9 to 18 are cross sections of the most prevalent forms of rails, both English and foreign.

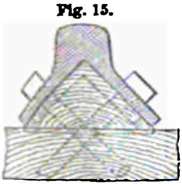
being immersed in the ballast. But it has been found to be unstable, difficult to pack and to drain from a propensity to suck up water beneath the head, and the head has been found liable to split. Lengths of this rail of five or six miles have been riveted together without any inconvenience having been experienced from expansion.

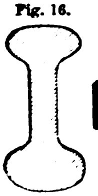
Fig. 15.



Seaton's Rail, Great Western.

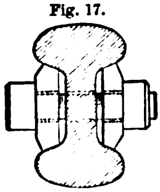
The length of rails is usually from 18 to 21 feet. Their durability depends chiefly on the quality of the iron employed; and heavy rails are less durable than light. Rails are tested by allowing a weight to fall upon one rail in (say) every hundred. In the rails of the Royal Swedish Railway a ram weighing two tons was

Fig. 16.



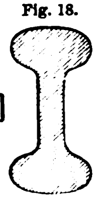
London and South-Western, 80 lbs.

Fig. 17.



Leicester and Hitchin, 92 lbs.

Fig. 18.

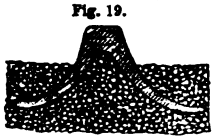


London and North-Western, 85 lbs.

allowed to fall from a height of twelve feet on a rail laid on supports four feet apart, but this test was unusually severe. In some cases the heads of the rails have been made of a superior iron, or of steel, by welding on iron of a superior quality or steel. But there is always the risk that the weld may not be sound and secure. Sometimes the tops of the rails are case-hardened. But the cheapening of steel by the Bessemer process is extending the production of rails made of steel throughout.

Joints of Rails.—The ends of the rails are cut off square, and (to allow of their expansion) a minute distance is left between them at common temperatures. At a temperature of 100° the ends are placed in contact; at a temperature of 0 they are laid at a distance of ·163 from one another. On the English lines the rails of each

Fig. 19.



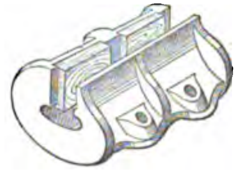
Barlow's Rail.

track break joint with one another; but on the American lines both joints are usually on the same sleeper. For many years the only fastening which united the ends of the rails was obtained by placing the ends in a long chair and keying them up together. But it is now usual not to place the contiguous ends in a chair at all, but to attach them together by means of plates bolted through the sides, the bolt holes being made slightly oval to permit expansion. It is reckoned that a variation in the temperature of iron of 10° or 12° produces a force of expansion equal to one ton per square inch of section; and in America, where the alternation of temperature is great, it has been found in some cases that unless space for expansion has been allowed, and the rails have been laid in cold weather with close joints, the track has in some places been raised vertically a foot, and has been bent out sideways two or three feet by the expansion of the rails. Sometimes on steep gradients the rails are found to have a tendency to creep to the lower end.

The joint chair usual on English lines weighs from 26 to 40 lbs. and the intermediate chair weighs from 18 to 26 lbs. Ramsbottom's chair is made of wrought iron, and is formed by rolling out a channel of iron with flanges on each side, and this is afterwards cast off in short lengths, each of which forms a chair. The sides of the chair are somewhat inclined, and pieces of iron or fishes are fitted on each side of the rail, making the total thickness equal to the width of the head; the rail with these fishes is then set in the chair, the bottom of which, however, it does not touch, and it jams itself tight by the weight rolling over it. In some cases the side wedges used to secure the rails in the chairs are of iron instead of wood, and sometimes, when of iron, they are made hollow to give a certain elasticity. Fig. 20 represents Parsons' wedge chair, which is formed with recesses, into which are introduced short pieces of wood with their grain directed against the rail, an iron wedge being driven in between the rail and the chair. One side of the wedge presses on the wood under this arrangement, and that side is barbed up with a few projections like those of a file, to prevent the key from working back.

Fig. 21 is a side view and cross section of a fish joint. The weight of the fishes is 22 lbs., and of the bolts, nuts, and washers $2\frac{1}{2}$ lbs. The bolts of fish joints are usually $\frac{7}{8}$ of an inch diameter. Many plans have been proposed to prevent the bolts and nuts from turning round and becoming loose; but the best appears to be to nick slightly the thread of the bolt with a chisel after it has been screwed up, as this will prevent it from unscrewing of its own accord

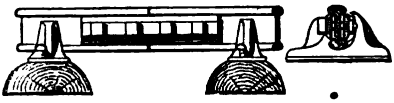
Fig. 20.



Parsons' Chair.

from vibration, and yet will not prevent it from being screwed up or unscrewed by a com-

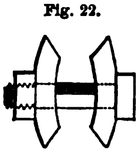
Fig. 21.



Adams' and Richardson's Fish Joint.

mon wrench, which will shear off the slight burr in the screw. Fig. 22 is a representation of Wild's grooved fish, of which the sides are grooved to hold the head of the bolt, and to catch the nut when it turns square with the groove. The weight of this pair of fishes is 22 lbs., and the weight of the four bolts and nuts is 4½ lbs.

Fig. 22.



Wild's Grooved Fish.

Switches.—In order to deflect a train from one line of rails on to another, movable rails called *switches* are employed, which at one end are fixed to a centre, while the other end, which is tapered to a point, is moved against the side of the rail by a horizontal rod and handle, to which a heavy weight is attached to bring back the switch to its normal position as soon as the handle is released. Switches are either single or double, the first being made with one movable rail, and the second with two. Double switches are usually employed for sidings, on the main line as they throw the rails less out of gauge and less disturb the continuity of the line. They are usually made out of the rails in common use upon the line. The subordinate features of their construction are very various, one main object sought to be attained being to gain sufficient strength in the point to prevent it from being crushed before the full breadth of the line is reached. In Wild's switch this end is attained by so tapering the point or tongue that its end is housed beneath the top of the fixed rail when shut against it.

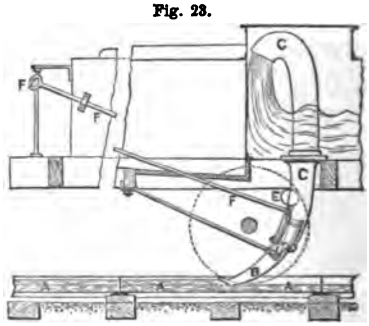
Turntables.—These are expedients, chiefly employed at termini, for transferring the engines and carriages from one line to another. A platform or table supported round the edge by rollers is made to turn upon a central pivot. The carriage or locomotive being pushed on to this platform, the platform is turned round until the wheels are brought opposite to the other set of rails upon which the carriage has to be delivered. A catch, then allowed to drop, fixes the table, and the vehicle is then delivered upon the other set of rails. The indications to be fulfilled in the construction of turntables are strength, steadiness under a passing load, small friction in turning, and as far as possible independence of foundations.

Traversers.—Instead of turntables traversers are sometimes used to transfer carriages from one line to another. A platform with rails laid upon it is made to move sideways on wheels beneath, and the carriage being run upon this platform is carried sideways until it comes opposite the other line. This plan, however, does not answer for transferring locomotives which have to be also turned round when set upon the other line.

Water Cranes.—To supply the locomotives with water, elevated tanks are erected along the line at suitable intervals, and a pipe with a swivelling arm like a crane is swung over the line, when the engine stops, to conduct the water from the tank into the tender. The construction of these swivelling pipes or water cranes is very various, and in some cases provision is made for heating them by a fire in the event of frost. Sometimes a roller pressed by a weight is made to act on an inclined plane on the side of the pipe, so as to swing back the pipe like a swing gate as soon as it is released, thus obviating the risk of leaving the crane standing across the line.

Supplying Water while running.—On the Chester and Holyhead Railway near Conway a long trough has been laid down between the rails, into which a scoop is dipped when the locomotive comes to that part, the water being thus lifted into the tender without stopping the engine. The form of this contrivance is shown by fig. 23, where A A is the trough, B the movable part or scoop of the pipe C, F is a

Fig. 23.



Feeding Tender while running.

handle by which the scoop is depressed, and E is a counterweight which brings the movable part of the pipe—and which swivels round a horizontal pin—back when the handle is released. The trough contains five inches of water, and the scoop dips two inches into it and scoops up that depth of water at speeds exceeding twenty miles an hour. But at lower speeds the water will not be delivered over into the tender. This contrivance effects a sensible saving of time in express trains, and it is found that the thin ice which can alone be formed in frosts during the intervals of passing trains does not interfere with its efficient action.

Resistance of Railway Trains.—In the early history of railways the resistance was considered to be directly as the speed. But it was subsequently shown by Dr. Lardner and others that it increased in a much more rapid ratio, and was in point of fact more nearly as the square

of the speed. More recently, however, it has been found that this rapid increase of the resistance takes place only on rough lines; and that on very smooth lines, when there is no side wind blowing, the resistance varies nearly as the simple speed.

Speed of Railway Trains.—The average speed of express trains on the London and North-Western Railway is, including stoppages, about 40 miles an hour; on the Great Northern, 39½ miles; on the South-Eastern, 37½; and on the South-Western, 35 miles an hour. Speeds of 60, 72, 78 and even 93 miles an hour have been attained for short distances. The London and North-Western runs a train over 82¾ miles in 1 hour 54 minutes, and the Great Western one from Paddington to Bristol, 117 miles, in two hours.

Consumption of Fuel per Mile.—The express trains on the London and South-Western Railway burn 17 lbs. of coal per mile, but on occasions have burnt as little as 14 lbs. The American express trains burn a cord of wood in from 20 to 30 miles. A cord of wood weighs 3,000 lbs., and 1¾ cord of wood is equal in heating power to a ton of bituminous coal.

Mountain Railways.—Railways have been carried over the Styrian Alps, and up the Ghauts in India, by employing powerful engines with many coupled wheels, and by constructing the line on a tolerably easy incline. They have been carried over parts of the Andes by employing stationary engines to pull up the trains by ropes; and more recently a line has been carried over Mont Cenis by forming the track with a deep central rail, on the opposite sides of which rollers are made to press by suitable mechanism, so as to grip the rail. By rotating these rollers by vertical spindles connected with an engine, the train is propelled up a very steep gradient at a low rate of speed. This appears to be the most suitable method yet introduced for surmounting steep inclines.

Railway, Atmospheric or Pneumatic. A species of railway in which the propelling power is the pressure of the atmosphere on one side of a piston or diaphragm and a partial vacuum on the other side. In one of the forms in which this principle was applied by Mr. Clegg, and which was tested some years ago on the West London Railway at Wormwood Scrubbs, and subsequently introduced on the Dalkey, Croydon, and South Devon lines, a large pipe was carried along the centre of each track, this pipe being partially exhausted by steam engines stationed at intervals along the line. A piston attached to the train travelled in this pipe, and being propelled forward by the air, which was allowed to press behind it, while a partial vacuum was maintained in front, the piston was carried forward, drawing the train with it. To enable the connection between the piston and the train to be maintained, a bent arm passed through a long slit on the top of the pipe. This slit was covered by a leather flap or valve extending the whole length of the line, the valve being made tight by tallow, which was soldered tight by a hot iron carried in the part of the train in the rear of the piston. Mr. Robert Stephenson, who reported upon this system in 1844, showed that it was both troublesome and wasteful, and was not likely to come into general use in competition with the locomotive, and it has since been removed from all the lines on which it had been introduced. The atmospheric system, however, or some modification of it, though not adapted for indiscriminate use as an economical system, seems likely to find special applications of importance, such as in ascending steep inclines, in working underground railways, and in conveying mails and merchandise through tubes. This last application has been carried out in London by the Pneumatic Despatch Company with success. But the power consumed relatively with the work done is very great. In August 1861 the experimental tube, which was subsequently put down between Eversholt Street and Euston Station for the transmission of the mails, was tested at Battersea, and it was found that, taking into account the pressure produced by the air and the distance traversed by the piston or carriage, and comparing the result with the indicated power of the engine employed to pump the air, only twenty per cent. of the engine power was utilised, while eighty per cent. was lost. On the line of tube between Euston and Holborn, similar results have been obtained. This tube is flat on the bottom and arched on the top, and is 4 feet broad and 4½ feet high. It is fitted with rails, on which a truck runs. The truck is made tight against the tube by an Indian rubber ring, so that it acts like a piston; and with a load on the truck of 10 tons, including the weight of the truck itself, a pressure of air of 4 ounces per square inch propelled the truck from Euston to Holborn, a distance of 1¾ miles, in 7 minutes. The pressure of air is obtained by a fan 22 feet in diameter, making 170 turns per minute, and the fan can be made either to suck or blow, or both; but the leakage is found to be greatest when the fan is made to blow, or to compress the air, and thus push the carriage on. The indicated power required to work the fan is found to be about 200 horses, and the efficacy is only 18 per cent., the loss being 82. This great loss may probably be reduced hereafter by the use of more suitable apparatus; and even with a large amount of loss the system appears to be suitable for especial purposes, where by any other known arrangement still greater evils would have to be encountered.

Railways, Law of. Companies for the construction of railways are now provisionally registered under the Companies Act 1862 until

their Act of incorporation is obtained. Each particular railway Act is called the special Act, and incorporates in its provisions those of the Clauses Consolidation Acts (Companies, Lands, and Railways, 1845 and 1863), which respectively govern, as to all essentials, the constitution of railway companies and their powers; the rights of shareholders and others who invest in the capital needed to enable the directors to carry on the business of the company; and the powers of the company to take and purchase land for the purpose of constructing the railway and works connected therewith. The special Act declares the amount of capital, the limited liability of each member, who is not chargeable on account of any debt or demand due from the company beyond the extent of his share in the capital of the company not then paid up; the number of directors, the line of the intended railway, tolls, and so forth. The company being now constituted, two meetings of shareholders, called *ordinary* meetings, must be holden every year, as provided by the Companies Clauses Consolidation Act 1845; extraordinary meetings can be convened by the directors as they may think proper. The special Act always names the first directors; afterwards they are elected by the shareholders. The powers of directors are fixed by the general Acts above referred to (the most important power, in a legal point of view, is that of making contracts on behalf of the company); and the directors are personally indemnified for all losses &c. which they may incur in the execution of such powers. The company obtains permission and compulsory power to take, or injuriously affect land for the purpose of their railway. Compensation under 50*l.* may be assessed by two justices: in higher cases by arbitration; by the verdict of a jury, to be summoned by the sheriff on a warrant issued by the company; by a surveyor named by justices in certain cases, where the party fails to appear before the jury. The legal powers which enable the company to construct the railway and necessary works are defined in the Railway Clauses Consolidation Acts, and are very extensive, but subject to many legal restrictions as to the mode of construction. The Board of Trade has the authority of sanctioning, within certain limits, deviations from the works originally undertaken; and it has also certain special authorities to superintend the line and works of a railway after it is opened; to regulate other matters; and, finally, to authorise the abandonment of railways. Railway companies have always hitherto been formed under special Acts of Parliament (incorporating since 1845 and 1863 respectively the general consolidation Acts of those years, above referred to), as the powers required for such an undertaking are too extensive to be obtained by agreement or otherwise without parliamentary sanction. It has, however, recently been provided by the Railways Construction Facilities Act 1862, that where all landowners over whose land a railway is proposed to be made are consenting parties, the promoters of the line may obtain the necessary powers without a special Act, by a certificate from the Board of Trade, the draft of which is to be previously submitted for the sanction of parliament; and in certain cases existing railway companies may obtain further powers (under the Railway Companies Powers Act 1864) by a similar certificate from the Board of Trade. But any such application to the Board of Trade may be rejected by the Board; and if it should be opposed by any railway or canal company which would be affected by the proposed certificate, further proceedings must be in parliament.

It appears to have been originally thought that railways, like highways, would be, to some extent at least, open to the use of the general public; and the Railways Clauses Consolidation Act 1845 contains provisions for the use of the railway, with engines and carriages, by companies and persons other than the company to whom the railway belongs, on payment of certain tolls; but it is found in practice that the difficulties of so doing are so great that the company owning the railway possesses a virtual monopoly of it, except where, as is the case on many lines, other companies have by special agreement or Act of Parliament obtained the power of running their trains over it and using the stations, &c.

Railway companies are as common carriers subject ordinarily to the general law of the land. The Railway and Canal Traffic Act 1854 contains various important provisions binding companies to afford all reasonable facilities for the receiving, and forwarding, and delivering of traffic without unreasonable delay, and without giving any person, or company, or description of traffic any preference or advantage, or subjecting the same to any prejudice or disadvantages, and otherwise regulating their rights and liabilities as carriers.

Rain (Ger. regen, akin to Lat. rigo, Gr. βρέχω, *to moisten*). In Meteorology, water falling from the atmosphere in drops.

The following generally received theory of rain was proposed by Dr. James Hutton in the *Phil. Trans. of Edinburgh* for 1787. The capacity of air for moisture, or the quantity of moisture which a given volume of air will hold, increases with the temperature, but in a much faster ratio than the temperature; and hence it follows that if two equal portions of air at different temperatures completely saturated with moisture are mingled together, a precipitation must take place from the inability of the mixture (which will have the mean temperature of the two portions) to sustain the mean quantity of vapour. For example, suppose that while the temperature increases in an arithmetical ratio, the capacity for retaining moisture increases in a geometrical ratio, and that at the temperature of 15 centesimal degrees air can hold 200 parts of moisture; then at 30 degrees it will hold 400 parts, and at 45 degrees 800 parts. Now, suppose two equal bulks of damp air, at the respective temperatures of 15

and 45 degrees, to be mixed together, the compound must contain 1,000 parts of vapour, or either half of it 500 parts; and the temperature of the compound will be 30 degrees. But at this temperature the air is saturated with 400 parts, and consequently there will be a precipitation of 100 parts from each of the given bulks.

It is obviously not necessary that the commingled portions of air should be fully saturated with moisture, as assumed in the above example: rain will be precipitated if the two masses approach the point of saturation, but the quantity will be proportionally less. It is also a consequence of the theory that for a given difference of heat the precipitation will be greatly increased at the higher temperatures; and this is conformable to experience, for showers are most copious during hot weather, and in tropical countries. The circumstances, therefore, on which, according to this theory, the quantity of rain precipitated in a given time depends, are the following: The previous dampness of the commixed portions of air; the difference of their respective temperatures; the elevation of their mean temperature; and the extent to which the mixture takes place.

The principal objection to this theory is, that the quantity of rain which actually falls in a given portion of time is often very much greater than can be supposed to be produced by any probable extent of cooling that can take place in the free atmosphere in that time, unless, perhaps, we have recourse to the supposition of a cold and a warm current driving swiftly in opposite directions, and continually mixing their conterminous surfaces. Sir J. Leslie (*Ency. Brit.* 'Meteorology') computes that if two currents of moist air were driving along in opposite directions, with velocities whose sum is 30 miles an hour, the one having a temperature of 70° of Fahrenheit, and the other of 50°, the deposition of moisture in the space of an hour would be equal to the height of an inch. If the sum of the opposite velocities amounted to 60 miles an hour, and the intermingling influence extended to but a quarter of an inch at the grazing surfaces, there would still be produced in the same time a fall of rain reaching to half an inch in altitude. These quantities agree sufficiently with observation in certain cases; but the objection still recurs that rain frequently falls from clouds which appear to move very slowly, and when consequently the supposition of such velocities is inadmissible. This difficulty has, however, been recently solved by Prof. Tyndall, who has proved that aqueous vapour possesses a high radiating power, and that consequently a stratum of moist atmospheric air can have its temperature rapidly reduced by the escape of its heat into space through the superincumbent dry air. In connection with atmospheric condensation it must also be borne in mind that the ascent of warm air, necessarily involving expansion, i.e. a motion of its particles away from each other, is always attended by considerable reduction of temperature, and hence, if the warm air be saturated or nearly saturated with moisture, condensation must occur from this cause independently of that which may arise from intermixture with colder air or from radiation.

Some extraordinary falls of rain have been recorded, the accounts of which, if not given on apparently unexceptionable testimony, would scarcely fail to be regarded as fabulous. On the 25th of October, 1825, a fall of 30 French inches (32 English), within 24 hours, occurred at Genoa; and on the 9th of October, 1827, there fell at Joyeuse, in the South of France, a quantity equal to 31 English inches within the space of 22 hours. (Prof. Forbes's Report on Meteorology, in the *Reports of the British Association for* 1840.)

Rain drops vary in size from perhaps the 25th to the 3rd part of an inch in diameter; and, like other falling bodies, descend with a continually accelerating velocity until the resistance of the air becomes equal to their weight, after which the descent is uniform. The terminal velocity is proportional to the square root of the diameter of the drop; but it is perhaps not possible to determine with certainty the actual terminal velocity corresponding to a drop of any given diameter.

The average quantity of rain which falls in a year at any given place depends upon a great variety of circumstances, as latitude, proximity to the sea, elevation of the region, configuration of the country and of the mountain ranges, exposure to the prevailing wind; and in general on the different local causes which influence climate. Humboldt estimates that the average depth of rain which annually falls at the latitudes of 0°, 19°, 45°, and 60°, may be taken respectively at 98, 80, 29, and 17 inches; but this estimate must be regarded rather as a rough approximation to the ratio in which the quantity decreases on going from the equator, than as indicating the actual averages at any particular place; and it is observed that though the annual depth be greatest towards the equator, the number of rainy days in the majority of places increases with the latitude.

The greatest depth of rain which has been registered at any place in a year is at Maranham, lat. 2½° S., and is stated by Humboldt to be 277 English inches. But this is greatly above the average, and indeed more than double the annual quantity which has been observed at any other locality. At St. Domingo the annual fall is estimated at 120 inches; at Cayenne, 116 inches; in the island of Granada, 112; at the Havannah, 91; at Calcutta, from 76 to 118; at Bombay, from 83 to 96; the island of Martinique, 87 inches; and at Sierra Leone, 86. Of European countries, Portugal appears to be the most humid, 123 inches having been observed at Coimbra in a year. The average depth at Paris is 19·1 inches (Arago, *Journal de Physique*, 1816); Berlin, 20·9; Brussels, 19; Florence, 41·3; Lyons, 39·5; Maestricht, 36·1; Marseilles, 18·4; Padua, 36·6; Petersburg, 18·2; Rome, 31·2; Rotterdam,

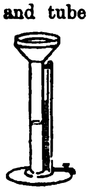
22·4; Stockholm, 18·7; Vienna, 17. For places in Great Britain the following averages were deduced by Dr. Dalton from observations of a number of years: Manchester, 36·140 inches; Liverpool, 34·118; Lancaster, 39·714; Kendal, 53·944; Dumfries, 36·918; Glasgow, 21·331; London, 20·686. Mr. Howard gives the annual average at London as equal to 24·9 inches; Professor Phillips that of York as 25·7; and Mr. Adie that of Edinburgh as 25 inches. On the theory of rain, see Kämptz, *Lehrbuch der Meteorologie*; Muncke, in Gehler's *Physicalisches Wörterbuch*; Daniell's *Meteorological Essays*, &c.

Rain-gauge, also called **Ombrometer, Udometer,** and **Pluviameter.** An instrument for measuring or *gauging* the quantity of rain which falls at a given place.

'The *rain-gauge* may be of very simple construction. A cubical box of strong tin or zinc, exactly ten inches by the side, open above, receives at an inch below its edge a funnel, sloping to a small hole in the centre. On one of the lateral edges of the box, close to the top of the cavity, is soldered a short pipe, in which a cork is fitted. The whole should be well painted. The water which enters this gauge is poured through the short tube into a cylindrical glass vessel, graduated to cubic inches and fifths of cubic inches. Hence, one inch depth of rain in the gauge will be measured by 100 inches of the graduated vessel, and 1-1000th inch of rain may be very easily read off.

'It is very much to be desired that, being of such easy construction, more than one of these gauges should be erected; or at least one placed with its edge nearly level with the ground, and another upon the top of the highest building, rock, or tree in the immediate vicinity of the place of observation, the height of which must be carefully determined, it having been satisfactorily ascertained that the height of the gauge above the ground is a very material element of the quantity of rain which enters it. The quantity of water should be daily measured and registered at 9 A.M.' (*Report of the President and Council of the Royal Society on the Instructions to be prepared for the Scientific Expedition to the Antarctic Regions*, 1840.)

A convenient form of the instrument is represented in the annexed figure, where the rain which enters the funnel is collected in a cylindrical vessel of copper, connected with which at the lower part is a glass tube with an attached scale. The water stands at the same height in the cylinder and glass tube, and being visible in the latter, the height is read immediately on the scale; and the cylinder and tube being constructed so that the sum



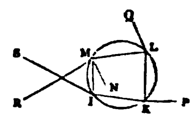
of the areas of their sections shall be a given part, for instance a tenth, of the area of the funnel at its orifice, each inch of water in the tube is equivalent to the tenth of an inch of water entering the mouth of the funnel. A stop-cock is added, by which the water is drawn off when the observation is made.

Rainbow (Ger. regenbogen). The brilliant-coloured arch which makes its appearance when rain is falling in the region of the sky opposite to the sun, and the sun is shining upon the rain-drops at the same time.

This well-known meteor presents, when perfect, the appearance of two concentric arches; the inner being called the *primary*, and the outer the *secondary* rainbow. Each is formed of the colours of the solar spectrum; but the colours are arranged in the reversed order, the red forming the exterior ring of the primary bow and the interior of the secondary. The innermost bow is a segment of a circle whose radius subtends an angle of about 42°; the radius of the outer subtends an angle of about 51°; and the common centre is situated in the prolongation of the straight line which passes through the centre of the sun and the eye of the spectator. From the conditions invariably accompanying its appearance, the colours of the rainbow were known at an early period to be produced by the sun's rays passing through the drops of falling rain; but the phenomenon is a complicated one, and was not fully and satisfactorily explained until Newton had discovered the compound nature of solar light, and the different refrangibility of the component rays.

In order to explain the phenomenon of the rainbow, let us suppose a beam of light admitted through a small hole in the shutter of a darkened room to fall on a spherical globule of water at I (fig. 1) in the direction S I, and trace the path of the light in the interior of the globule. On entering the globule at I it is refracted, and consequently decomposed,

Fig. 1.

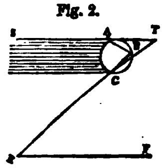


the rays of each colour being deflected under a different angle from its original direction. For the sake of perspicuity we shall confine our attention to the red ray. Let I K be the direction of the ray after the first refraction. On meeting the surface of the drop at K a portion of the light will effect its escape, and be again refracted in the direction K P, while the remaining portion will be reflected by the surface in the direction K L, the lines I K, K L making equal angles with a tangent at K. But on arriving again at the surface at L, this portion of the ray which was reflected from K will be again divided into two parts; one part will escape at L, and be refracted in the direction L Q, while the other part will be reflected by the surface, and proceed in the direction L M. At M the phenomenon will be repeated; part of the remaining light will escape and be refracted in the direction M R, and the other be reflected in the direction M N. This process will be repeated indefinitely; but the intensity of the light is diminished at each successive impact, and after a few reflections the quantity which emerges becomes insufficient to make an impression on the eye. All this may be shown experimentally by causing a beam of light to fall upon a glass

cylinder filled with water, and placed in a darkened room; the red light emerging at the points K L M will be seen when the eye is placed in the straight lines K P, or L Q, or M R.

Applying these considerations to the primary or inner bow, where there are only two refractions and one reflection, let A B C (fig. 2) be a section of a drop of rain made by the plane passing through the centre of the sun, the centre of the drop, and the eye of the spectator; and suppose the rays from the sun's centre to fall on it in the direction S A. Let E be the position of the eye of the spectator, whose back is turned towards the sun, and draw E F parallel to S A. Now suppose the line E T to be drawn so as to make with E F an angle of 42° 1′ 40″, and to meet the drop at C; then, since the whole of the anterior surface of the drop is illuminated by the rays S A, some one of those rays must fall on it under an angle of incidence, such that after being refracted at A, reflected at B, and again refracted at C, it will emerge parallel to C E, and consequently make with E F the maximum angle of deviation. The spectator will therefore see the red colour of the spectrum in the direction E C. But it is obvious that all these conditions will be fulfilled in respect of every drop of rain which the line E C will meet, on supposing it to revolve about E F as an axis at the same angle of inclination. Hence the red rays thus refracted form the surface of a cone, the axis of which is the prolongation of the straight line drawn from the centre of the sun to the eye; and as the eye of the spectator is at the apex of the cone, a circular segment of red light will be visible, the other part of the circle being cut off by the horizon.

Fig. 2.



What has now been said has reference only to rays coming from the sun's centre; but the same thing must happen with respect to rays coming from every point of the sun's disc; and as the sun's diameter subtends an angle of about 30′, the spectator will consequently see a band of red light of the breadth of about 30′.

The explanation which has now been given of the appearance of the red light applies to all the other colours of the spectrum, the only difference being in the value of the index of refraction. For the violet ray, in passing from air to water, the index is $109 \div 81$; we have therefore $n = 1{\cdot}3468$; and on computing from this the values of i, r, and D by means of the preceding formulæ, there results, approximately,

$$i = 58^\circ\, 40'\, 3'',\ r = 39^\circ\, 24'\, 20'',\ D = 40^\circ\, 17'.$$

In this case, therefore, the angle of maximum deviation is less than for the red ray, and hence the violet is within the red. The breadth of the violet band will obviously be the same as that of the red, as both depend on the same cause; namely, the magnitude of the sun's apparent diameter.

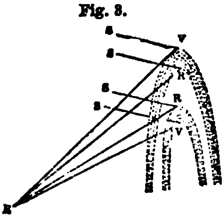
As the red and violet are the rays whose indices of refraction are the least and greatest respectively, all the other prismatic colours will lie between these two, and occupy bands of the same breadth, but with considerable blending into each other; but the distance between the centre of the red and the centre of the violet, being equal to the difference between their respective angles of maximum deviation, amounts only to $42^\circ\, 2' - 40^\circ\, 17' = 1^\circ\, 45'$. The whole breadth of the interior or primary bow is this quantity plus the sun's apparent diameter, or about 2° 15′.

The size of the bow depends upon the height of the sun above the horizon. When the sun is in the horizon, the bow will be a semicircle to a spectator on a plane; but on the summit of a mountain, he may see a segment greater than a semicircle.

The secondary bow is formed as shown in fig. 1.

In this case, the light suffers two reflections in the interior of the globule, and the path of a ray, as represented in fig. 1, is S I K L M R, and the deviation becomes least in respect of the red ray, and greatest in respect of the violet; the order of the colours is therefore reversed, the red occupying the innermost band and the violet the outermost, as represented in fig. 3, where E R is the red and E V the violet ray, the eye of the spectator being at E. The breadth from the middle of the red to the middle of the violet is 3° 10′, or nearly double that of the interior bow. The interval between the red of the interior bow and the red of the exterior is $50^\circ\, 59' - 42^\circ\, 2'$, or 8° 57′. All these values, deduced from the theory of refraction, are found to agree exactly with those found by actual measurement.

Fig. 3.



Dr. Halley, in the *Phil. Trans.* for 1700, has computed the diameters of the rainbows formed by three, four, and five reflections; but these bows are rarely if ever seen, the light being too faint to make an impression on the eye. Supernumerary or spurious rainbows are sometimes seen within the primary and without the secondary bow, and having the same order of colours as the bows to which they respectively belong. They are explained by Dr. Young on the theory of the interference of light. (*Phil. Trans.* 1804; *Lect.* vol. i. p. 470.) An inverted or distorted iris is sometimes observed lying on the ground, formed by the drops of dew suspended from the tops of the blades of grass, or from spiders' webs. In favourable circumstances lunar rainbows are sometimes seen; but their colours are faint and scarcely perceptible.

The first explanation of the true theory of the rainbow is usually ascribed (Newton's

Optics) to Antonio de Dominis, archbishop of Spalatro, and afterwards dean of Windsor, whose work, *De Radiis Visus et Lucis*, was published at Venice in 1611, but stated to have been written twenty years previously. It would appear, however, from the account of this work given by Boscovich, Montucla, Priestley, and Biot, that the merit of De Dominis was confined to a vague statement or surmise, unsupported by experiment, that the interior bow is formed by two refractions and an intermediate reflection. He gave no reason for the precise angle which its diameter subtends; and with respect to the exterior bow, his attempt to explain its formation is wholly erroneous. The true theory of the exterior bow, and the determination of the particular angles of deviation under which alone the rays transmitted to the eye are sufficiently dense to be visible, belong to Descartes. The explanation given by Descartes, in his *Dioptrics*, is complete in every respect, excepting as to the cause of the colours, the theory of which was supplied by Newton's great discovery of the unequal refrangibility of the different rays. (Montucla, *Histoire des Mathématiques*, vol. i. p. 700; Priestley *On Vision*, p. 107; Biot, *Traité de Physique*, tom. iii. p. 460.)

Raised Beach. In Geography, a beach is a shelving tract of sand or shingle washed by the sea or a fresh-water lake, and interposed between the water and the land on which vegetation grows. The beach of the ocean is, generally speaking, little more than the space between low and high water mark; the beach of a lake, that between the water marks of the highest and lowest ordinary level of the lake. An inland sea with little tide, such as the Mediterranean, has generally not much beach, except in embayed portions, where the waters rise or fall according to the prevailing winds. *Raised beaches* are tracts of shingle and gravel, indurated for the most part into the consistency of pudding stone or breccia, found on the sides of shelving ground at a level above that of some neighbouring lake or sea, in such a position as to leave no doubt that they had in ancient times been washed by its waters. They are found extending along our own coast, especially in Cornwall and Wales; they have been observed also very distinctly on the shores of the Mediterranean and the Baltic, and they abound in the vicinity of the great American lakes. They are valuable geological evidence of a recent change in the level, over distinct areas of former sea-bottom, now converted into dry land high enough to be beyond the tidal influence.

Raising Plate or **Upper Plate.** In Architecture, the plate or longitudinal timber on which the roof stands when in its place or pitched.

Raising a Siege. In Military language, abandoning a siege.

Raisins (Fr.; Ger. rosine). The dried berries of the Grape Vine, of which large quantities are annually imported, upwards of 300,000 cwt. having been received in this country in 1864, chiefly from Turkey and Spain. Some are wholly sun-dried, and these, which are the best, are called raisins of the sun. Others are first dipped in a ley, and then sun-dried; others which are dried in ovens, are of inferior quality. The raisins of Malaga are the finest, the muscatels from that district being the most esteemed of all.

Rajah (akin to the Sanscrit root râj, *to shine*: the word reappears in the Latin rex, regis, *a king*). A title given to the hereditary princes of the Hindus, who belong to the Cshatriya or warrior caste. [Caste.]

Rake (A.-Sax. racian). The Nautical term for *slope*, applied in several senses on board ship. The *rake of the stem and stern* is the distance by which the top projects beyond its base where it joins the keel. The *rake of a mast* is its slope towards the stern, causing its angle with the keel to be less than a right angle. The object of this rake is to diminish the plunging action of the ship's bows. It is a common form of masting in small sharp-bowed vessels. The *rake of the rudder* is its foremost edge, agreeing with the sternpost, and of course having the same rake.

To rake a ship, is to fire into her head or stern in the direction of her length, or along her decks. It is similar to what engineers term *enfilading*.

Ram (a Teutonic word). An instrument of modern warfare, reproducing on a vastly more powerful scale the beaked vessels of the ancients. The ram is a ship of extraordinary solidity and strength, propelled by engines of great power, and armed at the prow, below the water line, with a sharp heavy beak nearly pointed and diminishing to a sloping edge on the upper side. This beak is nearly solid, or at least of the strongest possible formation; and it is usually built as an independent adjunct to the ship, so that in the event of any very serious collision it may be buried in its victim, or carried away, leaving the vessel itself intact. Irrespective of this beak, the ram is constructed like any other iron-clad vessel. It may be of iron altogether, of wood with iron armour throughout, or of wood with its battery only protected by armour. Some rams have their batteries in broadside, others in revolving turrets, naval authorities being divided as to the relative advantages of the systems. The shape of the beak, flat beneath, and above inclining upwards towards the ship, presents the exact opposite of the ordinary cutwater in its action on the water; but the French naval architects maintain that the change is an improvement, the throwing off of water from the sharp edge preventing the formation of that mound of water which collects against the bow of the usual build and greatly impedes progress. The first practical use of the modern iron-clad ram was in 1862 in the Hampton Roads, where the Confederate ram 'Merrimac' destroyed several Federal wooden vessels with the greatest ease.

RAM. In Hydraulics. [HYDRAULIC RAM.]

RAM. In Zoology, the perfect male of the species of sheep, e.g. *Ovis Ammon*, *O. musimon*, *O. Vignei*, from one or more of which wild species the domesticated breeds have been derived. The castrate mal eis termed *wether*.

Ram, Battering. [BATTERING RAM.]

Ram-til (Hin. ram-tilla). One of the names of *Guizotia oleifera*, an oil-plant of India. The oil is commonly used as a lamp oil, and as a condiment.

Ramadan or **Rhamadan.** The name given to the great fast or Lent of the Mohammedans. It commences with the new moon of the ninth month of the Mohammedan year; and while it continues, the day is spent uninterruptedly in prayers and other devotional exercises. Even the night is passed by the more rigid of the faithful in the mosques, which are splendidly illuminated on this occasion; but, generally speaking, the arrival of sunset is the signal for a more than usual indulgence; and, on the third evening of the fast, the grand vizier commences a series of official banquets. The Ramadan ends on the day preceding the only other great festival of the Mohammedans, the BAIRAM, equivalent to our Easter.

Ramayana (Sanscr. *the career or travels of Rama*). The oldest of the two great Sanscrit epic poems, describing the life and actions of the hero Rama and his wife Sita, and especially Rama's expedition to Ceylon, to rescue Sita from the tyrant Rawana. For the age of the poem, see Max Müller, *History of Sanscrit Literature*, p. 41, &c. A translation of it was commenced by Messrs. Carey and Marshman (printed at Serampore); and another by A. W. von Schlegel (Bonn 1829). (*Historical Sketch of Sanscrit Literature*, from the German of Adelung, p. 117, &c.)

Ramentum (Lat. *a shaving*). In Botany, a thin brown foliaceous scale, such as appear sometimes in great abundance upon young shoots, and are especially numerous and highly developed upon the petioles and the backs of the leaves of ferns.

Ramists. In Philosophy, the partisans of Pierre Ramé, better known by his Latin name of Ramus, royal professor of rhetoric and philosophy at Paris in the reign of Henry II. He perished in the massacre of St. Bartholomew. His system of logic was opposed to that of the Aristotelian party; and during the latter half of the sixteenth century a vehement contest was maintained between their respective adherents in France, Germany, and other parts of Europe. (Hallam, *Literature of Europe*, vol. ii. ch. iii.) 'He conferred,' says the same writer, 'material obligations on science by denying the barbarous method of the schoolmen. What are the merits of his own method, is a different question.' (*Ib.* vol. i. ch. vii.)

Ramline. In Mast-making or laying a deck, a long line of cord so fastened as to designate the exact central line.

Rammelsbergite. An arsenide of nickel isomorphous with rhombic Iron Pyrites. It is named after Rammelsberg, the German chemist and mineralogist.

Ramnenses or **Ramnes.** [EQUITES; LUCERES.]

Ramp (Fr. rampe). In Architecture, a concave band, or slope, in the cup or upper member of any piece of ascending or descending workmanship. Thus, the ramp of a staircase railing is the inclined rail along which the hand of a person going up or down the staircase is led. The word *ramp* is, however, understood in this case to apply to the straight part exclusively.

RAMP. In Fortification, a road cut obliquely in the interior slope of the rampart, leading from the interior of the work to the terreplein.

Rampant (Fr.). In Heraldry, a term used to describe lions, tigers, bears, &c., when represented as standing erect on their hind legs.

Rampart (Fr. rempart). In Fortification, the mass of earth thrown up from the ditch inwards in order to give the defenders a commanding position over the ground in front. The term *rampart*, though strictly meaning the mound on which the parapet stands, generally includes the parapet itself. If it be of less height than thirty feet, it is liable to be taken by escalade. [FORTIFICATION.]

Ramphorhynchus (Gr. ῥάμφος, *a beak*, and ῥύγχος, *a snout*). A genus of Pterosaurian reptiles, in which the fore part of the jaw is without teeth, and may have been encased in a horny beak, but behind the edentulous production there are four or five large and long teeth, followed by several smaller ones. The tail is long, stiff, and slender. The *Ramphorhynchus longicaudus*, *R. Gemmingi*, and *R. Münsteri* belong to this genus. All are from the lithographic (middle oolitic) slates of Bavaria.

Rampion (Fr. raiponce, from Lat. rapum, *rape*). The garden name for *Campanula Rapunculus*, the fleshy roots of which were formerly cultivated and eaten in this country, as they still are in France and Italy.

Ramus (Lat. *a branch*). In Botany, a term applied to a branch or subdivision of a stem, *ramulus* being a little branch or ultimate subdivision. Hence the word *ramose*, which is applied to plants which produce branches (in contradistinction to such as are unbranched), or to those which are very much branched.

Ran. In Rope-making, a reel of twenty yarns.

Rana (Lat. *a frog*). The generic name of the tailless Batrachian reptiles, which have the hind legs longer than the fore, and webbed toes fitted for swimming, and not expanded at the extremity. Their head is flat, muzzle rounded, and the opening of their jaws large; the tongue in most of them is soft, and not attached to the bottom of the gullet, but to the edges of the jaw, with the free end turned backwards. There are but four toes to the anterior feet; the hind ones frequently exhibit the rudiment of a sixth.

There are no movable ribs to their skeleton: a prominent cartilaginous plate supplies the place of a tympanum, and renders the ear visible

externally. The eye is furnished with two fleshy lids, and a third, which is transparent and horizontal, concealed under the lower one. Inspiration is effected by the muscles of the throat, which, by dilating, draw in air by the nostrils, and by contracting while the nostrils are closed by the tongue compel the air to enter the lungs; expiration, on the contrary, is produced by the muscles of the lower part of the abdomen. The young frog, which is called a *tadpole*, is at first furnished with a long fleshy tail, and a small horny beak, having no other apparent limbs than little fringes on the sides of the neck. These disappear in a few days, and the hind feet of the tadpole are very gradually and visibly developed; the fore feet are also developed, but under the skin, through which they subsequently penetrate. The tail is gradually absorbed. The beak falls and discloses the true jaws, which at first were soft and concealed beneath the skin; and the branchiæ are absorbed, leaving to the lungs alone the function of respiration in which they participated. The eyes, which at first could only be discerned through a transparent spot in the skin of the tadpole, are now visible with their three lids. Tadpoles reproduce their limbs almost like salamanders.

The period at which each of these changes takes place varies with the species. In cold and temperate climates, the perfect animal passes the winter under ground, or in the mud under water, without eating or breathing; though if it be prevented from respiring during the summer for a few minutes by keeping its mouth open, it dies.

Rancierite. A variety of Hausmannite, resembling Pyrolusite.

Randanite. A kind of soluble silica, chiefly composed of infusorial remains, and found in France near Randon, in the Puy-de-Dôme.

Range. In Gunnery, the distance from the muzzle of a gun to the second intersection of the *trajectory* with the *line of sight*. The *range* is not accurately the distance to the point at which the shot impinges on the plane, unless that is also the point aimed at, but the difference is practically of importance only at short distances. In practice the *range* is usually measured from the muzzle of the gun to the point of impact on the object, or to the first graze of the projectile. The range depends on the *initial velocity*, the form and density of the projectile, the *angle of elevation* of the gun, and the difference of level between the planes upon which the gun and object respectively stand.

RANGE. On Shipboard, a length of cable equal to or slightly in excess of the supposed depth of water into which the anchor is about to be cast. It is lightly coiled on the deck, that it may run freely through the hawse-hole as the anchor falls. The term *range* is also used to denote a large cleat in a ship's waist for belaying the sheets and tacks of the courses.

Ranger. Formerly, a sworn officer of the king's forests, whose principal duty it was to see and enquire respecting trespassers in his bailiwicks, and present them at the next court holden for the forest; but now merely an officer of state. [FOREST.]

Ranidæ. The family of Batrachian reptiles, having as the type the frog (*Rana temporaria*, Linn.). [RANA.]

Rank and File. In the Army, all soldiers and non-commissioned officers bearing arms in the ranks are so called.

Ranters. A sect which originated in a secession from the Wesleyan connection, on the ground that the Wesleyans paid too much attention to the externals of public worship, and were deficient in zeal in open preaching in the streets and fields. They admit of female preaching; a thing unknown to every other body of Methodists. They are most prevalent in America.

Ranula (Lat. rana, *a frog*, to which it has been supposed to bear some resemblance). A tumour under the tongue, generally supposed to arise from some obstruction of the ducts of the salivary glands; some recent observations, however, render it probable that the disease often consists in the developement of a cyst in or about the salivary ducts under the tongue.

Ranunculaceæ (Ranunculus, one of the genera). An order of Exogenous polypetalous plants, in almost all cases herbaceous, inhabiting the colder parts of the world, and unknown in hot countries, except at considerable elevations. They are of great importance, from their usually poisonous qualities, as evinced by Aconite and Hellebore in particular, which are the roots of several species. Some of them are objects of beauty, as the Larkspurs, Ranunculus, Anemone, and Peony. [PÆONIA.] A few are simply astringent, as the *Coptis* or Gold-thread of North America. The plants of this order are readily known by having an indefinite number of hypogynous stamens, separate carpels, exstipulate undotted leaves, and a herbaceous stem.

Ranz des Vaches (Fr.; Ger. kuhreihen, *the call to the cows*). The name of the melody which the Swiss herdsmen are in the habit of playing on the Alpine horn, and sometimes of singing, when they drive out their herds to the mountains. It consists of a few simple intervals, and has a beautiful effect in the echoes of the Swiss mountains. The natives are said to be seized with irrepressible longings to return to their native country when they hear it played in a foreign land.

Rape (Lat. rapum, Gr. ῥάπυς). In Botany, the *Brassica Rapus*, a plant belonging to the cabbage family, cultivated in fields for its seeds, which are crushed for oil; and sometimes for its leaves, which are fed off by sheep. In Belgium another variety, called *Colza*, is cultivated for these purposes, the *Brassica Rapus oleifera*.

RAPE (Lat. raptus). In Criminal Jurisprudence, a well-known and detestable offence committed against women. Capital punishment for this offence was abolished in 1841. The substitute is penal servitude or imprisonment.

Rape. An Anglo-Saxon territorial division, of which the etymology is uncertain. Sussex is the only county divided into rapes; each containing three or four hundreds. These subsisted as military divisions at the time when Domesday Book was compiled. They were formerly under the superintendence of *rape-reves*, subordinate to the sheriff of the county.

Raphania (Lat. raphanus, Gr. ῥαφανίς, *the radish*). A disease supposed to be produced by eating the seeds of a species of *Raphanus*. It is attended by convulsive motions of the limbs, vomiting, and diarrhœa, and is classed by Cullen among the *neuroses*.

Raphanosmite. A name given to varieties of Clausthalite having part of the lead replaced by copper.

Raphanus (Gr. ῥάφανος, *a radish*). A genus of *Cruciferæ*, of which the most important species is the Common Radish, *R. sativus*. The Radish was extensively cultivated in ancient Egypt, but does not appear to have reached this country until A.D. 1548. The root, which is the part mostly used, is fleshy and variable in form, in some varieties fusiform, in others round like a small turnip, or semi-globular, and either of a reddish-purple, white, yellowish, or deep brown. The seed-pods are smooth, ending in a short pointed beak, and while young, green, and plump, are used for pickling, alone or with other vegetables; they are also considered a tolerable substitute for capers. It is, however, as a salad-root that radishes have from time immemorial been used. They are in perfection when of a moderate size and quite young. The flesh then abounds in a peculiar nitrous juice, which is much relished by vegetarians, and is considered to be a powerful antiscorbutic. Radishes are usually eaten raw with salt, or cut into slices and mixed in salads. When too large for a salad, they make an excellent dish if dressed and served like asparagus.

The Rat-tail Radish, *R. caudatus*, produces pods which sometimes are as much as three feet long. These, when properly grown, are quite tender and agreeably flavoured, and are eaten instead of the roots, which do not acquire a succulent condition in this species.

Raphe (Gr. ῥαφή, *a seam*). In Anatomy, a term applied to parts which look as if they had been sewn or joined together.

Raphe. In Botany, the vascular cord communicating between the nucleus of an ovule and the placenta, when the base of the former is removed from the base of the ovulum.

Raphia (Gr. ῥαφή). A genus of Palms, the three species of which are found in three widely separated but very limited localities in Brazil, tropical Africa, and Madagascar. The American species, *R. tædigera*, called the Jupati Palm, has cylindrical leafstalks, which measure from twelve to fifteen feet in length, and are used by the natives of the Amazon for a variety of purposes; the walls and partitions of their houses being often constructed of them, while baskets, boxes, &c., are made of strips of the smooth outer portion. *R. vinifera*, the Bamboo Palm, which grows on the west coast of tropical Africa, is employed for similar purposes by the Africans, who also make very pliable cloth and neat baskets of the undeveloped leaves. Palm-wine is obtained from it, whence its Latin specific name. The fruit spikes sometimes weigh as much as from 200 lbs. to 300 lbs.

Raphides (Gr. ῥαφίς, *a needle*). In Botany, certain needle-like transparent bodies found lying in the tissue of plants. They were formerly thought to be peculiar organs, but are now known to be the crystals of various salts.

Raphilite (Gr. ῥαφίς, and λίθος, *stone*). A variety of Asbestiform Tremolite, occurring in groups of delicate acicular crystals (whence the name) of a white or bluish-green colour. It is a silicate of magnesia and lime, and is found at Perth, in Upper Canada.

Rapparee. A wild Irish plunderer. The name is supposed to be derived from the rapery, or pike carried by such marauders.

Rappee. A name used to denote those snuffs which are prepared by grinding the tobacco to powder in a moist state.

Raptores (Lat. *plunderers*). Rapacious birds or raveners. The name of the order of birds called *Accipitres* by Linnæus and Cuvier, including those which live by rapine, and are characterised by a strong, curved, sharp-edged, and sharp-pointed beak, and robust short legs with three toes before and one behind, armed with long, strong, crooked talons.

Rarefaction (Lat. rarefacio, *I rarefy*). In Physics, an augmentation of the intervals between the particles of matter, whereby the same number of particles occupy a larger space. The term is used chiefly in speaking of the aëriform fluids, the terms *dilatation* and *expansion* being applied in speaking of solids and liquids. In the free atmosphere rarefaction is caused by diminishing the pressure, and hence the air becomes rarefied when it ascends. The limits to which rarefaction may be carried are not known; but it has been proved by experiments with the air-pump, that air may be rarefied so as to occupy a volume 13,000 times greater than it occupies under the ordinary pressure.

By first filling the receiver with carbonic acid gas, then rarefying by the pump as far as possible, and finally absorbing the small residuum of carbonic acid by solid caustic potash, rarefaction has recently been carried much further; nevertheless, Gassiot has proved that a long vertical tube containing this extremely attenuated atmosphere, still contains as much of it at the top as at the bottom.

Raskolniks (Russ. raskolo, *a division*). The name of the largest and most important body of dissenters from the Greek church in the Russian dominions. They designate themselves Starowerzi, or *the Orthodox*; but differ from the Greek church only in the outward forms of religion, and in maintaining a more strict ecclesiastical discipline. This body was

formerly subjected to persecution, but is now treated with comparative toleration, though its members are still excluded from the service of the state. Their number is said to be about 300,000.

Rasores (Lat. rado, *I scratch*). Gallinaceous birds, or scratchers. The name of an order of birds, including those which have strong feet, provided with obtuse claws for scratching up grains, &c., and the upper mandible vaulted, with the nostrils pierced in a membranous space at its base, and covered by a cartilaginous scale. [GALLINACEÆ.]

Raspberry (Gr. kratzbeere). The *Rubus Idæus*, one of our somewhat local wild plants, related to the bramble. There are many cultivated varieties, in which the fruit is much larger than in the original wild form. The grateful sub-acid fruit is highly valued for confectionery.

Raspberry-jam Tree. A colonial name for the Stinking Acacia of Central and Western Australia, the heavy wood of which has an odour resembling Raspberry jam.

Rat (A.-Sax. ræt, Ger. ratte, perhaps akin to Lat. rodo, *I gnaw*). The name of a large, destructive, and very prolific species of the genus *Mus* (*Mus decumanus*, Linn.), introduced into the British Islands from Asia; not, as is commonly believed, from Norway. It has spread over all the country, and multiplied at the expense of the old British species called the *black rat* (*Mus rattus*, Linn.). [MUS.]

Ratafia. A term applied to certain liqueurs or drams; it is said to have signified originally a liquid drunk at the *ratification* of an agreement. (Pereira *On Food and Diet.*) [LIQUEURS.]

Ratans, Rattans (Malay rotan), or **Canes.** The long slender stems of a species of *Calamus Rotang* and other allied species of Palm, which are among the most useful plants of the Malay peninsula and the Eastern islands, whence they are largely exported. For canework they should be chosen long, of a bright pale yellow colour, well glazed, and of a small size; not brittle or subject to break. They are purchased by the bundle, which ought to contain 100 ratans, having their ends bent together, and tied in the middle. In China they are sold by the picul, which contains from 9 to 12 bundles. Such as are black or dark-coloured, snap short, or from which the glazing flies off on their being bent, should be rejected. When stowed as dunnage, they are generally allowed to pass free of freight. The imports into this country are considerable. (*Com. Dict.*)

Ratchet. In Clock and Watch Work, the name given to an arm or piece of mechanism, one extremity of which abuts against the teeth of a *ratchet wheel*, and the other extremity is either freely jointed to a reciprocating driver for the purpose of communicating a continuous motion to the wheel, or is attached to a fixed centre to insure the wheel against reverse motion. In the former case it is also called a *click* or *paul*, in the latter a *detent*.

Ratchet Wheel. A wheel having teeth formed like those of a saw, against which the ratchet abuts. [RATCHET.]

Rate of Sailing of a Vessel. Various plans have been proposed for measuring the rate of sailing of a vessel, by various forms of the LOG, by which it is now measured; by the rise of water in tubes communicating with the sea; and (according to a suggestion by Captain Burney) by the pressure upon a body towed astern and pulling on a spring. But the violence and irregularity of the pull, and the uncertainty in reading the result, have probably combined to set aside this last plan, which, in theory, seems to promise some advantages; because the pressure, increasing as the square of the velocity, would show very small changes of velocity: for the same reason, however, the mean result shown in a heavy sea would be too great. A certain and simple method of ascertaining the velocity at any instant, with precision, is one of the most important desiderata towards the perfection of naval science.

Rate of a Ship. [NAVY.]

Rathoffite. A variety of Garnet found in Sweden, accompanied by calc spar and hornblende.

Ratification (Lat. ratus, *determined*, and facio, *I make*). The solemn act by which a competent authority gives validity to an instrument, agreement, &c. The term is ordinarily used in international law for the sanction given by governments to treaties contracted by their representatives. In French law, ratification is defined to be the approbation or confirmation of what has been done or promised. Thus, in many instances, a person, on attaining his majority, ratifies acts done by himself or his guardian in his minority. This ratification may be either express or tacit; the latter resulting, by implication, from his silence for ten years after attaining his majority.

Ratio (Lat.). In Geometry, this word is defined by Euclid (*Elements*, book v. def. 3) to be 'a mutual relation of two *magnitudes* of the same kind to one another in respect of *quantity*.' This definition has been much criticised. Dr. Barrow (*Lectiones Math.*), who calls it a metaphysical definition, since nothing in mathematics depends on it, or can be deduced from it, supposes that Euclid had probably no other design in making it than to give a general summary idea of ratio to beginners. It has been remarked, that as the word *quantity* in our language, if not quite synonymous with magnitude, has a signification only a little more general, the definition as above rendered is either tautological or unmeaning. Dr. Simson supposes it to be the interpolation of some unskilful editor. Leslie (*Elements of Geometry*) ingeniously supposes that the Greek word πηλικότης, which is usually translated *quantity*, may have reference to *multitude* or number, as well as to magnitude, and that Euclid's definition may be rendered as follows: 'Ratio is a certain mutual habitude of two homogeneous magnitudes with

respect to *quotity*, or numerical composition.' Dr. Wallis (*Opera Mathematica*, tom. ii. p. 665) translates the same word by the Latin *quantuplicitas*, which refers to the number of times the one magnitude is contained in the other. Dr. Peacock (*Algebra*, p. 309) remarks, that there is no geometrical definition of ratio by which the equivalence of different modes of representation may be ascertained as necessary consequences; and for this reason ratios in geometry are considered only in connection with each other, as constituting, or not constituting, a proportion. In arithmetic and algebra, a ratio may be defined as the fraction of which the numerator is the antecedent, and the denominator the consequent of the ratio; hence, in those sciences, the theory of ratios becomes identified with the theory of fractions. (For an account of what has been written on the subject of geometrical ratios, see Camerer's *Euclid*, Excursus ad lib. v. Berlin 1825.)

Ratios, Prime and Ultimate. [Prime and Ultimate Ratios.]

Ration. In the Army, a portion of food allowed to each soldier for his daily maintenance. [Provision.]

Rational (Lat. rationalis). An algebraic or arithmetical quantity is said to be *rational* when it can be expressed in finite terms without the aid of symbols denoting the extraction of roots; when it cannot be thus expressed, the quantity is termed *irrational*.

Rational Horizon. In Geography, the plane passing through the centre of the earth parallel to the *sensible horizon* of the place to which it is referred. [Horizon.]

Rationalism. The opinion is not uncommon that the history of thought from the age of the Reformation has exhibited a new element, and that this element is the spirit of rationalism. From this it is inferred that some systems, religious or political, may be based on rationalism, while others may exist in spite of it or without it. The inference and the opinion from which it is drawn seem to be alike fallacious. Rationalism is, strictly, nothing but the exercise of reason, and involves the rejection of all conclusions for which evidence sufficient to satisfy the reason cannot be produced. The truth or the falsehood of the system depends, not on the spirit by which they who accept it are animated, but by the adequacy or inadequacy of the evidence alleged in support of it. The conclusions must in every case accord or disagree with the facts for which they account, or are supposed to account. Hence, the most absurd and superstitious systems are as much the growth of rationalism as any which we regard as wholesome or enlightened. The assertion that devils carried witches to midnight feasts in the Harz forest, was as rationalistic as the assertion that there could be no such feasts because there are no devils. The transportation by devils was a rational explanation to account for an alleged fact. The whole question is thus resolved into one of evidence; and it is precisely in the knowledge of the nature of evidence that modern thought is pre-eminently distinguished from that of the middle ages. The complete ignorance of mediæval jurists on this subject is sufficiently shown by the use of Ordeals, judicial combats, and compurgations, as means for ascertaining whether an alleged fact did or did not take place; and as long as men were content with the vaguest notions, or with no notions at all, on the sources of knowledge, their practice could not be essentially changed. But as soon as the dawn of physical science began to reveal the connection of phenomena, the idea of likelihood took root, and the conclusion was reached that the sole source of knowledge is experience, and that in judging of matters of fact no authority or evidence can be admitted except that of experience. Hence, in the case of all theories which professed to explain facts, it was seen that the theory was inadmissible until every single proposition involved in it was established by adequate evidence. Thus, on the hypothesis of devils transporting witches through the air to nocturnal banquets, the explanation cannot be received until it has been proved not only that there are devils, but that they act in some particular ways. That the judges and inquisitors of the middle ages were not competent persons in the ascertainment of facts, must be felt by all who have compared their judicial processes with those of the most recent times, defective, and in part wrong, as these are still admitted to be. During those ages, deliberate and wholesale perjury was the rule, not the exception; and witnesses and magistrates alike were as incapable of sifting the evidence for alleged facts in their own day, as they were of testing the histories or traditions of former times.

It follows that the superstitious beliefs of the middle ages fell, not from the growth of a new spirit, or in spite of an overwhelming amount of evidence in their favour, or from any conviction of their absurdity, but because it became continually more manifest that the assertions dignified by the name of evidence were no evidence at all, and because any alleged facts could be admitted only as agreeing with the standard of likelihood afforded by general experience. The more recent theories of astronomy owed their success not to any supposed absurdities in older theories, but to the measure in which they accorded with or explained phenomena. The idea of antipodes, or of the revolution of the earth round the sun, was scouted as utterly absurd; yet no ideas could be more true. Socrates was firmly convinced that the heat of summer was caused by the approach of the sun to the earth, and regarded the supposed fact as striking evidence of design in the creation of the world; but, although there was nothing absurd or childish in his conviction, it does not square with facts, and therefore must be given up. Hence, it became clear that all assertions could not, as such, stand on the same footing or carry the same weight. The statement that a man was seen

walking at a given hour in a given place must be tested like all other statements; but we at once exclude on the ground of unlikelihood or impossibility the statement that he was seen carrying his head under his arm.

But although rationalism is not a new element introduced into modern thought as contrasted with that of the middle ages, the gradual discovery of the nature of evidence has established conclusions fatal to the authority of any system which refuses to submit its claims to full and fair examination. These conclusions are the result of researches in the physical world, but they issue in the establishment of toleration, which, it has been said, is justified by scepticism, and by nothing else; for, until men are convinced that reason alone can guide us to the truth of facts, toleration is an impossibility. As soon as they are so convinced, they must see that different minds will, from the same facts viewed in different aspects, form different conclusions, although the truth of the facts remains the same, and cannot be divided. For a more full examination of the subject, see an able review of Mr. Lecky's *History of Rationalism* in *Fraser's Magazine* for November 1865.

As the application of the word *rationalism* to denote the writings of any particular school of theologians is thus shown to be inappropriate, it becomes unnecessary to compare the writings of so-called rationalists in Germany, or elsewhere, with those of writers who differ from them only in the degree of evidence on which they are prepared to admit the truth of particular statements or theories. It may be enough to say that the name *Rationalists* has been applied especially to the school of Paulus and other German writers, who seek to convert the miraculous narratives of the New Testament into a relation of ordinary occurrences. Thus, the feeding of the multitudes with the loaves and fishes is explained by the statement that when at the bidding of Christ the disciples had produced their little store, others also brought out what they had with them, and thus a meal was provided for the whole crowd. Measured by the modern standard of likelihood, such explanations may perhaps be considered as involving difficulties scarcely less than those of the narratives for which they profess to account. The influence of such a school was not likely to be lasting, and it was succeeded by another, commonly known as the mythical, which regards the Gospel records as assertions of floating myth round a nucleus of historical fact. For the history of these two schools, see Mackay, *History of the Tübingen School and its Antecedents.*

Ratlines. Small horizontal lines or ropes extended between the several shrouds on each side of a mast, thus forming the steps of ladders for going up and down the rigging and masts. To *rattle* the rigging, is to fix these ratlines.

On ship-rigged masts, the shrouds are ratlined up to the topmast-head: in small vessels or on sloop-rigged masts, only to the top of the lower-mast.

Ratoffkite. A granular or earthy blue variety of Fluor, from Ratoffka in Russia.

Ratoons or **Rattoons** (Span. retoño). The young shoots of the Sugar-cane, *Saccharum officinarum.*

Rattany. [RHATANY.]

Rattlesnake. One of the most deadly of poisonous serpents is so called, from the peculiar rattling instrument at the extremity of the tail, formed of several horny flattened rings, loosely attached together, which move and rattle whenever the animal shakes or alters the position of the tail. These rings increase in number with the age of the animal, and it is asserted that it acquires an additional one at each casting of the skin. The generic name of the rattlesnake, *Crotalus* (Gr. *κρόταλον, a rattle*), relates to the above-mentioned peculiarity. Two species are well distinguished; viz. the *Crotalus horridus* of the United States, and the *Crotalus durissus* of Guiana. The genus is peculiarly American. In common with the boa, the rattlesnakes have simple transverse plates beneath the body and tail. Their muzzle is hollowed by a little round depression behind each nostril. The habits of the rattlesnake are sluggish; they move slowly, and bite only when provoked, or for the purpose of killing their prey. They feed principally upon birds, rats, squirrels, &c., which it is believed they have the power of fascinating.

Rattlesnake Root. The root of the *Polygala Senega*, a stimulant said to be a serviceable remedy in cases of the bite of the rattlesnake.

Rauchkalk (Ger.). A variety of Dolomite, occurring in the Zechstein of North Germany. The signification, *smoky limestone*, refers to its dark colour and bituminous odour.

Ravelin (Fr.). In Fortification, a work composed of an ordinary rampart with a ditch in front, forming two faces meeting in a salient angle, on the perpendicular produced, and directed so as to receive flank defence from the body of the place. It is bounded at its gorge merely by a counterscarp, so that its interior may be exposed to the fire of the works in its rear. Within the ravelin, but separated by a ditch, is constructed a work called the *redoubt of the ravelin.* [FORTIFICATION.]

Raven (A.-Sax. hræfn: for the history of the root *ru* or *kru*, from which the name is derived, see Max Müller's *Lectures on Language*, first series, 348). A species (the largest known in Europe) of the restricted Linnæan genus Corvus, found from Greenland to the Cape of Good Hope, and from Hudson's Bay to Mexico. It is also met with in the Sandwich isles. Ross has pointed out that it is one of the few birds capable of enduring the severities of heat and cold without undergoing any change of plumage. Pied individuals are not unfrequent. It shares with other members of the genus the habit of pilfering shiny objects,

which are of no use to it, either as food, or to aid in the construction of its nest.

Ravenala. A fine Mussaceous plant found in Madagascar, and remarkable for its large leaves and palm-like habit. It forms a noble tree, which the French call the Traveller's Tree, probably on account of the water which is stored up in the large cup-like sheaths of the leafstalks, and which is sought for by travellers to allay their thirst. The very large broad oblong leaves are used as a thatch to cover huts. The seeds are edible, and the blue pulpy aril surrounding them yields an essential oil.

Ray (Lat. radius, *a ray*). A genus of cartilaginous Plagiostomous fishes, recognisable by their horizontally flattened and broad disc-shaped body, which is chiefly composed of the immense pectoral fins, the jointed and branched rays of which diverge, like the rays of a fan, and support a broad duplicature of the skin, which is continuous anteriorly with that of the side of the flattened head; whence the name of the genus. The *Raiæ* of Linnæus are now divided into many subgenera, of which the sting ray, eagle ray, electric ray, fire flare, skate, &c. are the respective types.

RAY. In Botany, the spreading ligulate florets in the flower-heads of the *Compositæ*.

RAY. In Geometry, a straight line, of unlimited length, drawn through a fixed point. [PENCIL.]

RAY. In Optics, a beam of light propagated in a straight line from some luminous point. A ray of white light may be divided by refraction into a number of distinct rays of different colours. [REFRACTION.]

Rayah. The designation by the Turkish government of its non-Mohammedan subjects, who pay the capitation tax. Under Bajazet I. the taxable rayahs in European Turkey were numbered at 1,112,000. At present the tax paid by 'unbelievers' consists in a compensation for freedom from military service. This amounts to rather more than half a million sterling annually. The number of the non-Mohammedan element in the Turkish dominions is computed at fourteen millions out of a population of thirty-five millions, but the proportion of Christians is probably underrated.

Rayonné, Rayonnant or **Radiant.** In Heraldry, a line in zigzag supposed to represent the rays of the sun, or what is commonly called *vandyked*. [HERALDRY.]

Razee (Fr. rasé, Lat. rasus, *shaved* or *scraped down*). The term used for any vessel cut down to a less number of decks, as a two-decker to a frigate, &c. By razeeing, the draught of water is diminished, while the centre of gravity is lowered, and the qualities of the vessel have generally, though not invariably, been improved.

Re. The French and Italian name for the note corresponding to our D.

Re-enter. In Engraving, a word which denotes the passing of the graver into those incisions of the plate, so as to deepen them, where the aquafortis has not bitten in sufficiently.

Re-entering Angle. In Fortification, an angle of which the point projects inwards, towards the work.

RE-ENTERING ANGLE. In Geometry, an angle of a polygon is said to be *re-entering*, when its vertex and the polygon itself fall on the same side of the line joining the two corners of the figure between which the angle is situated. [POLYGON; SALIENT ANGLE.]

Re-entering Places of Arms. In Fortification, spaces provided at the re-entering angles of the counterscarp for the assembly of troops either for sorties or defence. They are formed by carrying the crest of the glacis outwards so as to form a salient angle or an arc of a circle.

Reach (A.-Sax. recan; Ger. reichen; Gr. ὀρέγω, *to stretch out*). That portion of the length of a river in which the stream preserves the same direction.

Reaction. In Mechanics, this term is best defined by Newton's third law of motion, according to which 'action and reaction are equal and in contrary directions;' in other words, the mutual actions of two bodies are always equal and in opposite directions. Thus, when a pistol is fired, the reaction on the holder is equal to the action on the ball.

Reaction, Reactionary. In Politics, words which seem to have been first used to denote the tendencies of those who, after the violent changes effected by the first French revolution, were desirous of bringing back the former state of things; and hence applied in similar cases.

Reaction Wheel. [HYDRAULIC DANAIDE.]

Reader. In Ecclesiastical matters, one of the five inferior orders in the Roman Catholic church. In the church of England, a reader is a deacon appointed to do divine service in churches and chapels of which no one has the cure. There are also readers (priests) attached to various eleemosynary and other foundations. (Hook's *Church Dictionary*.)

READER. In Printing, the person whose duty it is to read proofs in a printing office, and mark all kinds of errors for correction.

Reagent. In Chemistry, bodies which serve to detect the presence of others are termed *reagents* or *tests*.

Real. A Spanish coin. [MONEY.]

Real Actions. In English Law, real actions were formerly the appropriate legal remedy for the recovery of lands, tenements, and hereditaments. It is obvious that land wrongfully held can always be restored to the right owner, while goods may have perished or been consumed, and the term *real action* probably originated in the circumstance that the plaintiff in such a proceeding demanded the specific thing (*res*) abstracted, and not, as in the case of a *personal* action (*actio in personam*), satisfaction in damages to be paid personally by the wrongdoer in respect of some injury done to person or property. The common division of property into *real* and *personal* arose, no doubt,

from this distinction between the legal remedies appropriated to each class respectively. Real actions were of a very complicated nature, and in modern times were almost entirely superseded in practice by the action of *ejectment*, which by a series of ingenious legal fictions had been moulded so as to afford a more prompt and satisfactory remedy for the same class of injuries. [EJECTMENT.] They were ultimately abolished by statute (3 & 4 Wm. IV. c. 27), with two or three exceptions, the most important of which is the action of *quare impedit*, which still forms the common process for trying the right to an advowson, and has recently been remodelled and simplified.

Real Presence. [TRANSUBSTANTIATION.]

Real Property. Real property is commonly said to consist in *lands*, *tenements*, *and hereditaments*. The first of these terms needs no explanation; the second refers to the circumstance that all land in this country is still considered to be the subject of *tenure*, and to be held either of the crown or of some inferior lord; and the third expresses what logicians would term the *difference* of real property, viz. that it descends to the heir wherever held in perfect right 'unless disposed of by will,' and is thus distinguished from personal property (goods and chattels), which, if possessed in equally absolute right, vests in the executors or administrators of the party, for the benefit of his legatees or next of kin. The original division of property was, no doubt, into *immovables* and *movables*; lands, tenements, and hereditaments being included in the first class, while the second was known as goods and chattels. The terms *real property* and *personal property* appear to have originally arisen from the technical distinction between real actions and personal actions, the respective legal remedies appropriated to the two classes of property. [REAL ACTION.] In the course of time, however, so many fresh kinds of property have arisen and become common, that 'the simple division into immovable tenements and movable chattels is lost in the many exceptions to which time and altered circumstances have given rise. Thus shares in canals and railways, which are sufficiently immovable, are generally personal property, whilst a dignity or title of honour, which one would think to be as locomotive as its owner, is not a chattel but a tenement.' (Williams *On Real Property*.) Thus, again, a lease for any number of years (even a thousand) is personal property, because the most ancient leases were farming leases, and the farmer was regarded rather as a bailiff than as the owner of an interest in land. Accordingly, the classes of property are now more commonly distinguished by the terms *real* and *personal*, than by the old division into tenements and hereditaments, goods and chattels, although these phrases, and particularly the word *hereditaments*, are of frequent use in legal documents as convenient and comprehensive terms. Real property is again subdivided into *corporeal* and *incorporeal* property, the former term denoting land with its visible adjuncts recognised by law as appertaining to it, consisting principally of things growing, erected, or fixed thereon, and the latter term including advowsons, rights of way and common, offices, dignities, franchises, rents, and the like. The great practical distinction between corporeal and incorporeal property formerly was that the latter, being incapable of manual transfer, was alienable by writing only, while corporeal property might be transferred by the delivery of possession accompanied by certain solemnities. Real property of every description, however (except copyhold), is now commonly transferred by deed. [COPYHOLD; TENURE.]

Realgar. Native tersulphide of arsenic; composed, when pure, of 70 per cent. of arsenic and 30 of sulphur. It occurs crystallised and massive, of various tints of aurora-red, chiefly in Hungary and Transylvania. Artificially prepared Realgar is used as a pigment; the ancients, who employed it for the same purpose, called it Σανδαράκη or Sandarac.

Realism. In Philosophy, this term has two distinct meanings, as used in contradistinction to *idealism* or to *nominalism*; in the former case it relates to the theory of perception, in the second to the theory of abstraction and generalisation. For the first, see IDEALISM and PERCEPTION; for the second, NOMINALISTS, SCHOLASTIC PHILOSOPHY, SCOTISTS, and THOMISTS.

Ream (A.-Sax.; Dutch riem, Dan. reem). A quantity of paper, consisting generally of twenty quires of twenty-four sheets each. The printer's ream contains 21½ quires, or 516 sheets. [PAPER.]

Reaping (A.-Sax. ripan, akin to Lat. rapio, Gr. ἁρπάζω, *to seize*). Cutting down corn or pulse with a sickle, hook, or scythe, or by a reaping machine. These operations are more advantageously performed when the corn or pulse is not quite ripe, than when it is thoroughly ripe; because in the latter case the seeds are apt to drop out in the process of handling, turning, and drying.

Reaping Machine. Since the International Exhibition of 1851, the American reaping machine, then first shown in this country, has gradually won its way in English agriculture, and there are now many counties in which much the larger portion of our corn crops are cut by it. The American reapers by Hussey and M'Cormick, and others, are, however, no doubt of English or Scottish origin, being essentially the same as the reaper invented long ago by the Rev. Mr. Bell of Forfarshire, and used ever since upon the farm of his brother. The cutting apparatus is an oscillating horizontal knife, having an edge either serrated, or if smooth presenting deep almost finger-shaped cutters. It oscillates through slots in a number of fixed horizontal fingers, which, as the machine is drawn or pushed forwards, hold the straw of the standing corn amidst which they project while the

oscillating knife is continually cutting it. The corn as it is cut falls upon a platform extending backwards from the cutting apparatus, and thence it is either raked in sheaves by a man who rides upon the machine, or it is there received upon a revolving web by which it is carried to one side and let fall in a swathe upon the stubble. The use of the reaping machine is a welcome economy in harvest time, when hand labour is costly, and when rapidity as well as efficiency of work is of the utmost consequence.

Rear (Fr. arrière). Formerly, when a fleet advanced in order of battle in three lines, the hindermost was the rear line or squadron, and furnished the title of the *rear-admiral*, the third officer in command, the first two lines being under the admiral and vice-admiral. At the present day this formation of a fleet is obsolete; but the title survives in the rank of rear-admiral, who represents the third, and lowest permanent, grade of flag officer. The French style this officer a *contre-amiral*.

Rear-check Carriage. In Artillery, a garrison carriage which has a block of wood in rear, resting on the platform, and no rear axle-tree or trucks.

Rear Guard. That part of an army, regiment, or detachment, which marches after the main body. The rear guard brings up stragglers, and protects the rear of the main body of troops.

Reason (Lat. ratio). Like most of the terms in the science of mind, the word *reason* has been employed in a great variety of significations. Dugald Stewart takes it in its widest sense, and comprises under it all the operations of the intellect upon the materials of knowledge which are furnished in the first instance by sense and perception. Its office is to distinguish the true from the false, right from wrong, and to combine means for the attainment of particular ends. Mr. Hume, however, withdraws the discernment of right and wrong, and of the beautiful and its contrary, from the domain of reason; and, on the other hand, also, denies the certainty of the truth which it enunciates. Locke in one passage declares reason to be the faculty which finds out the means, and rightly applies them, to discover either the certain agreement or disagreement of two ideas, or their probable connection. But, in another place, it is said to be conversant with certainty alone; while the discovery of that which, as probable, enforces a contingent assent or opinion, is ascribed to an especial faculty, which is called the judgment. Bird, on the other hand, confines the latter term to the apprehension of intuitive truth; but agrees so far with Locke as to make it one part of reason, of which the other part is reasoning, both demonstrative and moral. On the whole, however, it is clear that in the mind of Locke the terms *reasoning* and *reason* were nearly, if not quite, equivalent. But reasoning and deduction, it is urged by others, are evidently not the source either of the dignity or the authority of the human intellect, for if there were not in the human mind something primary, unconditional, and absolute, to which all reasonings might be referred, as to their source and foundation, the discursive process would proceed into infinity, and its conclusions be, as Hume asserts that they are, without any power to enforce assent. Hence it is maintained that there are unquestionably in the human mind certain necessary and universal principles, which are themselves above proof, but the authority for all mediate and contingent principles, and that that which is thus above reasoning is the reason.

In the language of English philosophy, the terms *reason* and *understanding* are nearly identical, and are so used by Stewart; but in the critical philosophy of Kant a broad distinction has been drawn between them. Reason is the principle of principles; either speculatively verifies every special principle, or practically determines the proper ends of human action. Approximately, it may be called the sum of what, in Scotch philosophy, has been denominated the laws of man's intellectual constitution. The understanding, on the other hand, is coextensive with the vernacular use of reason; It is that which conceives of sensible objects under certain general notions, which again it compares one with another, or with particular representations of them, or with the objects themselves. It is, therefore, the faculty of reflection and generalisation. But the act of comparison is called a *judgment*; and the understanding, when it enunciates its conceptions, becomes also the faculty of judging. But the truth of a proposition which is not identical cannot be immediately certain. To prove it, recourse must be had to other propositions previously admitted; i.e. the understanding must deduce one judgment from another, and so it becomes the discursive faculty, or reasoning. Further, in discovering these mediate truths, and in the regular and methodical disposition of them for the purpose of conclusion, as well as in the selection of means for the accomplishment of its ends, it exhibits itself as a power of adaptation.

The faculty of generalisation has its necessary result in articulate speech; and the ultimate distinction between human nature and that of brute animals is found in the possession by man of this power of abstraction, and not in a contrast of brute instinct with human reason. [Language.]

Reaumuriaceæ (Reaumuria, one of the genera). A small natural order of hypogynous Exogens, referred by Lindley to the Guttiferal alliance, and related to *Hypericaceæ*. They are distinguished by their oblique glandular petals, their few shaggy seeds, and their long distinct styles. *Reaumuria vermiculata* is used at Alexandria as a cure for the itch.

Rebate (Fr. rebattre, *to beat down*). In Architecture, the groove, recess, or channel sunk on the edge of any piece of material.

Rebate. In Trade, a discount or allowance for prompt payment. It is employed in a somewhat different sense in estimating the

assets of a bank. When a bank discounts a bill of exchange, it pays or gives credit to its customer for the bill, minus the market or special rate of discount charged for the postponement of its claim as the negotiator. When, therefore, the present value of the securities held by a bank is estimated, it is necessary to value the bills which it possesses according to the time which they have to run before reaching maturity, and deduct the sum so estimated from their nominal value.

Rebec. A Moorish word, signifying a stringed instrument somewhat similar to the violin, having three strings tuned in fifths, and played with a bow. It was introduced by the Moors into Spain.

Rebellion, Civil. In Scottish Law, by a peculiar fiction, a debtor who disobeys a charge on letters of horning to pay or perform in terms of his obligation was accounted a rebel, by reason of his disobedience to the king's command contained in the writ. (Sir W. Scott, *Antiquary*, ch. xviii.) The penal consequences formerly attaching to this construction of the law were abolished by 20 Geo. II. c. 50.

Rebellion, The Great. In English History, the revolt of the Long Parliament against the authority of Charles I. is commonly so denominated.

Rebus. An enigmatical representation of a name or thing by using figures for letters, syllables, or parts of words: thus an eye, and a ton or barrel, represent the family name of Eyton, an instance of a rebus borne by way of device, as they very commonly were. The term is said to be derived from an annual practice of the priests of Picardy, which consisted in satirising the people of their vicinity on the recurrence of the Carnival in ingenious squibs, entitled 'De *rebus* quæ geruntur.' [DEVICE.]

REBUS. In Heraldry, a coat of arms alluding to the name of the bearer (otherwise called *armes parlantes*) is also called a *rebus*; e.g. three trouts for Troutbeck, three cups for Butler, &c.

Rebutter. In Law, the fifth stage of the pleadings in a suit, or the plaintiff's answer to the defendant's rejoinder. [PLEADING.]

Receiver. In Chemistry, this word generally denotes a globular vessel applied to a retort, and in which the *distillate* or product of distillation is collected or received. The bell-glass placed upon the plate of an air-pump is also called a *receiver*. [RETORT.]

Receiving Stolen Goods. The act of receiving stolen goods, knowing them to be stolen, is, in English Law, a felony by statute. Since the last criminal law enactments (24 & 25 Vict. c. 96) there are three ways of proceeding against a receiver: (1) as for a substantive felony, whether the principal felon has, or has not, been convicted; (2) as an accessary after the fact, where the principal felon has been convicted, or is amenable to justice; (3) jointly with the principal in the same indictment.

Receptacle (Lat. receptaculum, *a storehouse*). In Botany, this term has several significations, denoting, 1. that part of a flower upon which the carpels are situated, or, in other words, the apex of the peduncle, or summit of the floral branch, of which the carpels are the termination; 2. that part of the ovary from which the ovules arise, and which is commonly called the placenta; 3. that part of the axis of a plant which bears the flowers when it is depressed in its developement; so that, instead of being elongated into a rachis, it forms a flattened area, over which the flowers are arranged, as in *Compositæ*. There is thus the receptacle of flowers, which is the *clinanthium*; the receptacle of fruits, which is the *torus*; and the receptacle of ovules, which is the *placenta*.

The part of the vein to which the spore-cases of ferns are attached is also called a *receptacle*; whether it be exserted, as in *Trichomanes*, or dorsal, as in *Polypodium*.

Receptacles of Oil. In Botany, the name applied to those cysts which occur in the cellular tissue of plants, and contain an oily secretion, as in the dotted leaves of the Orange.

Receptacles of Secretion. In Botany, the cavities formed in the interior of plants into which the natural secretions drain.

Recess of the Empire. In History, the name given in judicial language to the decrees of the German diet. They are thought to have been so termed from being pronounced at the time when the diet was about to *recede* or separate. [DIET.]

Recession of the Equinoxes. [PRECESSION.]

Rechabites. A religious order among the ancient Jews, instituted by Jonadab, the son of Rechab, who charged them to abstain from wine, from building houses, and from planting vines. These rules were observed by the Rechabites with great strictness. (Jer. xxxv. 6.) In recent times, a branch of the body called *teetotallers* has assumed the name of Rechabites.

Recipe (Lat.). The symbol ℞ at the head of a medical prescription generally means *recipe*, or 'take.' Dr. Paris says this character is a relic of the astrological symbol of Jupiter, a planet under the ascendency of which herbs were often collected or prepared. (*Pharmacologia*.)

Reciprocal (Lat. reciprocus). In Arithmetic, the quotient resulting from the division of unity by any number. Thus, $\frac{1}{2}$ is the reciprocal of 2; and, conversely, 2 is the reciprocal of $\frac{1}{2}$.

Reciprocal Equations. A reciprocal equation is one which remains virtually unaltered when the unknown quantity is replaced by its reciprocal. Thus in order that the equation $F(x)=0$ of the n^{th} degree may be a reciprocal one, the following relation, where A is some constant, must be identically satisfied—

$$F(x)=Ax^nF\left(\frac{1}{x}\right).$$

From this we conclude that in reciprocal equations the coefficients of terms equidistant

from the extremities must be *numerically* equal. These coefficients, however, may be effected with like or unlike signs, and thus two classes of reciprocal equations must be distinguished. A reciprocal equation of odd degree has necessarily a root equal to -1 or $+1$, as it belongs to the first or to the second class; these roots being equal to their own reciprocals. A reciprocal equation of the second class can have no middle term, when its degree is even, since terms equidistant from the extremities have equal and opposite values; it has, however, -1 as well as $+1$ for roots. This being the case, it will readily be understood that *every reciprocal equation can be depressed* by division by $x+1$, $x-1$, or x^2-1, *to a reciprocal equation of the first class and of even degree*; i.e. to one whose terms, equidistant from the extremities, have coefficients equal in magnitude and sign. This latter equation may be also depressed, by one half, by the substitution $x+\frac{1}{x}=y$, and any value of y being found, the corresponding two values of x will merely require the solution of the quadratic $x^2-yx+1=0$, which is itself reciprocal. Hence we may say that the solution of a reciprocal equation of odd degree $2m+1$ may always be reduced to that of an ordinary equation of the m^{th} degree, whilst the solution of one of even degree $2m$ may be made to depend upon that of an equation of the m^{th} or $(m-1)^{th}$ degree, accordingly as the given equation belongs to the first or to the second class.

The binomial equations

$$x^n+1=0 \text{ and } x^n-1=0$$

are clearly reciprocal. The depressed equation in y upon whose solution that of the given equation depends will here have all its roots real. [ROOTS OF UNITY.]

Reciprocal Lines. In Statics, the lines of action of any two forces mechanically equivalent to a given system of forces. [FORCES, COMPOSITION AND RESOLUTION OF.]

Reciprocal Polars. Two curves S and S′ are said to be *reciprocal polars* when each tangent of the one is the polar with respect to any *auxiliary conic* Σ of a point on the other. The reciprocity here assumed results from the fundamental property of poles and polars, in virtue of which the polars of all points in a line pass through the pole of that line, and the poles of all lines through a point lie in the polar of that point. [POLES AND POLARS.] From this it follows that if S′ be the locus of the poles of the tangents of S, the latter will necessarily have the same relation to the former; for the tangent of S′ joining two consecutive points will necessarily have for its pole the point on S which is the intersection of the corresponding consecutive tangents or polars of these consecutive points. The consideration of the properties of polar reciprocals enables us to double all purely graphical (and even many metrical) properties of curves. The *method of reciprocal polars*, by means of which this is done, was first systematically employed by Poncelet (Crelle's *Journal*, t. iv.); it is an application or illustration of the great *principle of duality* which obtains in all geometrical theorems. Of two reciprocal polars the order and class of the one are respectively equal to the class and order of the other. For if m points of C lie in a line, m tangents of C′ pass through a point. One curve will have as many multiple tangents as the other has multiple points, and the order of multiplicity will be the same in both. To a stationary point on one will correspond a stationary tangent on the other, and to the cuspidal tangent will correspond the point of inflexion. Thus from the fact that a curve of the m^{th} order with δ double points and κ cusps is of the class

$$n=m(m-1)-2\delta-3\kappa$$

[POLES AND POLARS], we may conclude that a curve of the n^{th} class with τ double, and ι stationary tangents, is of the order

$$m=n(n-1)-2\tau-3\iota.$$

Thus two of Plücker's well-known equations are at once deducible from the other two. [SINGULARITIES OF CURVES.]

Reciprocal polar surfaces are similarly defined, one being the locus of the poles of all tangent planes of the other with respect to an auxiliary quadric surface. The properties of such curves and surfaces are discussed in most modern text-books; most fully, however, in the works of Poncelet, Chasles, Steiner, and Salmon. When the auxiliary quadric is a circle or sphere, one of the reciprocal polars is usually termed the *polar reciprocal*, or simply the *reciprocal* of the other.

Reciprocal Proportion. The relation which exists between four magnitudes such that, taken in order, the first has to the second the same ratio which the fourth has to the third, or the first has to the second the same ratio which the reciprocal of the third has to the reciprocal of the fourth.

Reciprocal Spiral. [HYPERBOLIC SPIRAL.]

Reciprocant of a Quantic. The tact-invariant of the system composed of that quantic and $x\xi+y\eta+$&c. . . It is also a contravariant of the quantic. [CONTRAVARIANT.] Geometrically, the reciprocant is synonymous with the polar reciprocal. [POLAR RECIPROCAL.]

Reciprocity (Lat. reciprocus, *alternating*). In Political Science, the term usually applied to the principle of securing, in commercial treaties between nations, mutual advantages to the same extent, e.g. the admission, mutually, of certain goods, supposed to be practically equivalent to each other, duty free, or at equal duties on importation. This principle is clearly different from that by which one nation seeks to impose the receipt of its own productions by another state on better terms than those on which it receives the productions of the latter; which was at one time considered a great stroke of diplomatic wisdom. But it is

equally different from (though it may be combined with) that of mere free trade. A nation, renouncing for itself the practice of imposing any differential duties whatever, either in favour of its own produce, or that of one nation as against another, has in reality no *reciprocity*, strictly so called, to which it may lay claim; although it will, of course, be its interest to induce other nations, by treaty stipulations as well as other means, to waive *their* differential duties. A treaty such as that of Mr. Gladstone's with France cannot in strictness be described as grounded on *reciprocity* principles, these being used only as auxiliary to a greater and more general purpose. [TREATY.]

Recitative (Ital. recitativo, from Lat. recitare, *to recite*). In Music, a species of singing having some resemblance to ordinary reciting. It is used in operas, &c. to express some action or passion, or to relate a story, or reveal a secret or design; and though written in true time, the performer may alter the parts of the measure as he thinks most suitable to produce certain effects, those that accompany him being dependent on his pleasure. The use of recitative was suggested in 1594 by Ottavio Rinuccini. (Hallam, *Literary History*, part ii. ch. vi. § 5.)

Reckoning (A.-Sax. recan, Ger. rechnen). In Navigation, the estimated place of a ship, calculated from the rate as determined by the log, and the course as determined by the compass, the place from which the vessel started being known. *Dead reckoning* means the same as *reckoning*, due allowance being made for drift, lee-way, currents, &c.

Reclinate (Lat. reclinatus, *turned backwards*). In Botany, bent down on some other part. The term is applied to parts which fall gradually from the perpendicular, as the branches of many trees or shrubs.

Reclination (Lat. reclino, *I bend back*). In Dialling, the angle which the plane of the dial makes with a vertical plane which it intersects in a horizontal line.

Recluse. The common title of a class of religious persons in Roman Catholic countries. [INCLUSI.]

Recognisance. In Law, an acknowledgement of a debt upon record. By a fiction of law, the obligation which a party enters into before a court of record or magistrate duly authorised, with condition to do some particular act—as to appear at the assizes, keep the peace, &c.—is in the form of a recognisance; the party acknowledging himself to be indebted to the crown, the plaintiff, &c., with condition that the obligation shall be void on performance of the thing stipulated.

Recoil (Fr. recul). In Artillery, the motion of a piece of ordnance or small-arm in a direction opposite to that in which the projectile is thrown. It is caused by the pressure of the gas upon the bottom of the bore, in the direction of the axis, equal to that which acts upon the projectile. It exerts a very destructive effect upon the gun-carriage.

Reconnaissance (Fr.). The term applied to the examination of the features of a country or the position of troops, with a view to military movements, such as the march of troops from one station to another, without reference to an enemy; the advance upon ground occupied by an enemy whom it is intended to force; the retreat before an enemy; or the taking up a position for defence. An officer sent on a reconnaissance should always make a sketch, and for this purpose he should be able to sketch rapidly, accurately, and clearly, by means of the eye and hand, unaided by instruments, the chief features of the country or position reconnoitred.

Record (Lat. recordor, *I call to mind*). Literally, an authentic account of any fact or transaction in writing, contained in rolls of parchment, wood, or any other durable substance, and preserved in a court of record. [ARCHIVES.]

RECORD. In Law, the authentic testimony in writing, contained in rolls of parchment, of the judgment of a superior court, and of the other proceedings in a case. Records are said to be of three kinds: judicial records; ministerial records on oath, being offices or inquisitions found; records made by conveyance or consent, as fines, recoveries, or deeds enrolled. [COURT.] Trial by record is used where a matter of record is pleaded in any action, as a fine, judgment, &c.; and the opposite party pleads *nul tiel record*, that there is no such record existing. On this issue is joined, which can be tried only by inspection of the record.

The public records of the kingdom are now under the superintendence of the Master of the Rolls. A public record office has been established, and arrangements have been made for the more convenient custody, arrangement, and inspection of the records.

Recordari Facias Loquelam (Lat.). In Law, a writ to remove proceedings out of an inferior court to the Queen's Bench or Common Pleas. It is now obsolete.

Recorder. The chief judicial officer of a borough or city exercising within it the jurisdiction of a court of record, whence his title has been said to be derived, though it seems likely that the term was anciently applied to any person present at a judicial proceeding and to whose remembrance or record of what had taken place the law gave credit in respect of his personal or official dignity. The jurisdiction of recorders was formerly of varying extent, but it has been remodelled and rendered uniform by the Municipal Corporations Act (5 & 6 Wm. IV. c. 76) and subsequent statutes in all cities and boroughs to which those Acts extend, and abolished in places of minor importance. In criminal matters it is now, in general, equal, within its area, to that of the quarter sessions of a county; in civil matters it has been for the most part superseded by the modern county courts. Recorders were formerly chosen without restriction by the corporations with which they were connected; but by the existing muni-

cipal system, the appointment is vested in the crown, and the selection is confined to barristers of a certain standing. The city of London is not affected by the municipal corporation Acts, and the recorder there is still elected by the court of aldermen, and his jurisdiction and duties are regulated by custom.

RECORDER. The name of a musical instrument, somewhat resembling the flageolet, formerly in use in this country. It had a peculiarly pleasing tone; hence Milton speaks of

—— The Dorian mood
Of flutes and soft recorders.

Recovery or Common Recovery. In Law, a mode of assurance in the form of a fictitious action, by means of which conveyances were made by various tenants possessed of limited rights in real property (more particularly by tenants in tail). It was formerly the usual means by which the entail of a landed estate was barred or cut off; but by stat. 3 & 4 Wm. IV. c. 74 common recoveries are abolished, and a new mode of conveyance for the use of tenant in tail substituted for them, to the great improvement of the law. [FEE TAIL.]

Recruit (Fr. recruter, Ital. reclutare, *to recruit*). A soldier is so called from the time of his enlistment till he has completed his course of drill. In order to obtain recruits for the army, the United Kingdom is divided into districts in charge of recruiting officers, the actual enlistment of recruits being carried on by non-commissioned officers under them. Acceptance of a shilling from a recruiting sergeant as an earnest of the queen's bounty constitutes an act of enlistment, but the recruit cannot be attested before a magistrate till twenty-four hours have elapsed from his enlistment, nor after a longer time than ninety-six hours. The present system of obtaining recruits at the public-house, and too often by aid of the excitement caused by strong drink, tends to bring a bad class of men into the service, many of whom afterwards desert, or are constantly committing offences against discipline; and it would probably be far greater economy to add to the inducements to remain in the army, and so draw to it a better class of men.

Rectangle. In Geometry, a right-angled parallelogram. When the adjacent sides are equal, it becomes a *square*. The area of a rectangle is numerically expressed by the product of the two numbers which express the lengths of its adjacent sides, and hence the term *rectangle* is sometimes, but incorrectly, used for *product*.

Rectangular. A term synonymous with right-angled. Thus *rectangular co-ordinates* denote co-ordinates which are referred to axes at right angles to each other. A *rectangular parallelopiped* is one whose plane angles are all right angles.

Rectification (Lat. rectus, *straight*, and facere, *to make*). In Geometry, the determination of a straight line, whose length is equal to that of the arc of a curve. The problem requires the integral calculus. If the curve be entirely in one plane, the length of the arc is $\int\sqrt{dy^2+dx^2}$; or if it be a curve of double curvature, its length is $\int\sqrt{dx^2+dy^2+dz^2}$. In both cases the equations to the curve usually enable us to express the differentials in terms of a single independent variable and its differential, and thus to prepare the expression for integration.

It will, however, very rarely happen that the rectification can be obtained in finite terms, as the substitutions generally introduce radical expressions under the symbol of integration, which are hardly ever so connected with the rational parts as to be susceptible of finite integration; hence it has been an object with mathematicians to transform the expressions into others, the successive terms of which are so related as to diminish at a very rapid rate. In this case, the approximation to the value of the arc is rendered comparatively easy. The first curve which was rectified was the semicubical parabola; and the merit belongs to Wm. Neil, whose rectification was published in 1657. Two years later the same curve was rectified by Van Heureat, in Holland.

RECTIFICATION. A Chemical term, generally implying a second or more frequently repeated distillation; thus, *rectified spirit of wine* means spirit which has been redistilled, and by which it is to a great extent freed from water, or rendered stronger.

Rectification of the Circle. [QUADRATURE.]

Rectifying Plane, Line, and Surface. The plane through the tangent of a non-plane curve which is perpendicular to the osculating plane is called the *rectifying plane*; it is manifestly at right angles to the normal plane as well as to the principal normal, and consequently contains the binormal. Two consecutive rectifying planes intersect in the *rectifying line*, which is the generator of the *rectifying* (*developable*) *surface* enveloped by all such planes. The rectifying surface plays an important part in the theory of non-plane curves. It was first introduced into the theory of such curves by Lancret. (*Mémoires des Savans Étrangers*, t. i. 1805.) The cuspidal edge of the rectifying developable is sometimes called the *rectifying edge*; its angle of torsion, being the angle between two consecutive rectifying planes, is equal to the angle of total curvature of the original curve, i.e. to the angle between two consecutive principal normals, to both of which latter the rectifying line is perpendicular. The primitive curve is a geodesic line on the rectifying developable, since the principal normal through which its osculating plane passes is also a normal to the surface. By unfolding the rectifying developable, therefore, the curve will become transformed to a right line. It is to this property that the rectifying surface owes its name. The rectifying surface is the *surface of centres* of greatest curvature of the develop-

able osculatrix [CURVATURE], for the rectifying plane is clearly a principal normal plane of this surface, so that any two consecutive normals of the latter, if they intersect at all, must do so in the rectifying line of the curve. The latter is consequently the axis of the osculating right cone of the developable osculatrix or of the curve itself. [OSCULATING RIGHT CONE.] The rectifying line is parallel to the shortest distance between two consecutive principal normals; hence the plane of a rectifying line and the corresponding principal normal cuts the consecutive principal normal in a point of the line of striction on the skew surface formed by these normals. But this plane is obviously a principal normal plane of the rectifying developable itself, so that the line of striction of the skew surface of principal normals lies on the surface of centres of curvature of the rectifying developable. For other properties of the rectifying surface, the reader is referred to the works cited under the term CURVE.

Rectilineal or Rectilinear Figure. In Geometry, a figure bounded by straight lines.

Rector (Lat. rector ecclesiæ, *ruler of the church*). Properly, the person or parson who has the charge and care of a parish church. In many parishes, however, before the Reformation, the great tithes [TITHES] had been appropriated by religious societies, who appointed a vicar (*vicarius*), usually one of their own body, to perform the services, leaving him the small tithes as his remuneration; and the greater and smaller tithes thus came to be distinguished as *rectorial* and *vicarial* respectively, and the term *rector* to be appropriated to the owner of the great tithes of a parish, whether the parson or some other person or body corporate. [IMPROPRIATION.] The rector, whether lay or clerical, is bound to repair the chancel of the church, leaving the nave to the care of the parishioners.

The term *rector* is also employed in Scotland to designate the head master of a public school or academy.

Rectrices (Lat. rectrix, *one who rules* or *guides*). The name of the tail-feathers of a bird, which, like a rudder, direct its flight.

Rectum (Lat. *straight*). The last portion of the large intestines; so named from an erroneous notion of the old anatomists that it was straight.

Recumbent (Lat. recumbo, *I lie down*). In Zoology, when a part is leaning or reposing upon anything.

Recurrent Nerves. Two branches of nerves from the *par vagum*, in the cavity of the thorax, are so called; they are distributed to the muscles of the larynx and pharynx.

Recurring Decimal. [CIRCULATING OR RECURRING DECIMAL.]

Recurring Continued Fraction. A continued fraction in which one or more quotients continually recur. [CONTINUED FRACTION.] It is sometimes called a *periodic continued fraction*.

Recurring Series. A series, two or more of whose consecutive terms are always connected by a given constant relation. The recurrence, it will be observed, is in the *law* which governs the formation of the series, and not in the *terms* of the latter. The term *recurring series*, however, is usually restricted to a series of the form

$$a_0 + a_1 x + a_2 x^2 + \&c. \ldots$$

where the coefficients a_n, a_{n-1} &c. of $k+1$ successive terms satisfy a given *linear* relation of the form

$$a_n + A_1 a_{n-1} + A_2 a_{n-2} \ldots\ldots + A_k a_{n-k} = 0.$$

Such a series is further said to be a *recurring series of the k^{th} order*, since each term is manifestly a linear function of the k preceding terms. The last equation expresses the *law of recurrence* of the series, and the expression

$$1 + A_1 x + A_2 x^2 + \ \ldots\ A_k x_k,$$

formed from it in a sufficiently obvious manner, is termed the *scale of relation* of the series. Every rational fraction of the form

$$\frac{f(x)}{F(x)},$$

where $F(x)$ exceeds $f(x)$ in degree, can be at once developed in a recurring series of which $F(x)$ will be the scale of relation, and conversely the generating fraction of a given recurring series will have its scale of relation for denominator; the numerator may easily be determined, by the method of indeterminate coefficients. The general term of recurring series may always be found when the linear factors of the scale of relation can be determined. In most text-books on algebra, these methods are fully described.

Recurvate (Lat. recurvatus, *crooked*). In Botany, this term is applied to parts which are bent back, but not rolled back as when revolute.

Recusants (Lat. recuso, *I refuse*). In English History, a term applied to those who refused to acknowledge the king's supremacy as head of the church. Of these the greater number were Roman Catholics.

Red. [CHROMATICS.]

Red Book. The name given to a book containing the names of all persons in the service of the state. The *Red Book of the Exchequer* is an ancient record, in which are registered the names of all who held lands per baroniam in the time of Henry II.

Red Copper-ore. Native dioxide of copper, or Cu_2O, containing 88·8 per cent. of copper and 11·2 per cent. of oxygen. It is of a deep red colour, which usually can only be seen by transmitted light. The variety crystallising in the octahedral form is called Cuprite; a lighter red fibrous variety is called Chalcotrichite, or Plush Copper-ore; while the massive or earthy kind is known as Brick or Tile Ore (Ziegelerz). It occurs in almost all copper mines among the gossans or oxidised portions of the lodes near the surface, especially in Cornwall and South Australia. The finest sin-

gle crystals were formerly obtained at Chessy near Lyons.

Red Fire. A pyrotechnical compound which burns with a beautiful red or pink flame. It consists of nitrate of strontia, mixed with charcoal and a little sulphur and chlorate of potassa.

Red Iron-ore. A name under which are included those varieties of Hæmatite which have a non-metallic or submetallic lustre.

Red Lead. An oxide intermediate between the protoxide and peroxide of lead. [LEAD; MINIUM.]

Red Lead-ore or **Crocoisite.** Native monochromate of lead; composed, when pure, of 31·3 per cent. of chromic acid and 68·7 oxide of lead. It occurs massive and crystallised of various tints of hyacinth-red, in Siberia, Brazil, Hungary, &c. The artificial salt is used as a pigment, but the colour has the disadvantage of not being permanent.

Red Marl. The name given to a portion of the Triassic series in England. [GEOLOGY.]

Red Precipitate. The peroxide of mercury, obtained by the decomposition of nitrate of mercury by heat. [MERCURY.]

Red Sea. This long, narrow, but deep channel between Arabia and Africa is separated from the Mediterranean only by the narrow and low isthmus of Suez, and connects with the Indian Ocean by the still narrower straits of Bab-el-Mandeb. It is remarkable for the desolate regions adjoining the bare volcanic rock on its shores and bottom, and the high temperature of its waters, which rapidly increases from Suez towards the straits until it amounts to upwards of 84°. This is only two or three degrees below the temperature of the oceanic warmth equator of the Pacific, and is the more trying to travellers because the sea is narrow and not exposed to any cooling winds. The navigation of the Red Sea is dangerous, and there are many coral reefs as well as much volcanic rock. [SUEZ CANAL.]

Red Silver-ore. [PROUSTITE; PYRARGYRITE.]

Red Snow. The common name of *Protococcus nivalis*, a minute alga, which in an incredibly short space of time produces large patches of a brilliant scarlet on the surface of snow in Arctic or Alpine regions.

Red Wood. The name of an Indian dyewood, obtained from *Pterocarpus Santalinus*. The Red Wood of the Turks is the wood *Cornus mascula*; that of the Bahamas comes from *Ceanothus colubrinus*; that of Jamaica, from *Gordonia Hæmatoxylon*; and that of the timber trade from *Sequoia sempervirens*.

Redan (Fr.). In Field Fortification, a work consisting of two faces, forming a salient angle. A *double redan* is composed of two redans joined together, thus forming a re-entering angle for mutual defence. [FORTIFICATION.]

Reddendum (Lat. *to be restored*). In Law, the technical term for a clause reserving rent which in a lease usually begins with the words *Yielding and paying*, &c.

Reddle (from *red*). A soft argillaceous peroxide of iron, occurring in opaque compact masses of various shades of light brownish-red, which sometimes passes into nearly brick-red. The best specimens, used for crayons, are brought from Germany; the common kinds, used for marking sheep and for coarse paints, are procured in large quantities from the carboniferous limestone of the Mendip Hills in Somersetshire, from the Forest of Dean in Gloucestershire, and Wastwater in Cumberland, as well as at Brixham and other places in Devonshire from Devonian limestone. The Reddle found at Rotherham in Yorkshire is the best material known for polishing optical glasses.

Redemptorists. A religious order founded in Naples by Liguori in 1732, and revived in Austria in 1820. They are bound by the usual monastic vows, and devote themselves to the education of youth. They style themselves members of the order of the Holy Redeemer, whence their name; but they are also often called *Liguorists*, from the name of their founder.

Redoubt, more correctly **Redout** (Fr. redoute, Ital. ridotto). In Fortification, an enclosed work, without flanking defence from its own parapets. [FORTIFICATION.]

Redruthite. A name given by Brooke and Miller to Copper Glance, magnificent crystallised specimens of which have been obtained from the mines near Redruth in Cornwall.

Reducing Scale. A scale used by surveyors for turning links into roods and acres by inspection.

Reductio ad Absurdum. [ABSURDUM.]

Reduction. The process of separating a metal out of a metallic oxide, sulphide, &c. In some cases this is effected simply by heat, but generally by the joint action of heat and some deoxidising agent; upon the large scale, charcoal, coke, or coal is almost always resorted to. [SMELTING.]

REDUCTION. In Arithmetic, the changing of quantities from one denomination to another.

Reduction of Figures. In Practical Geometry, the description of figures similar to given ones, but of different (generally smaller) dimensions. The pentagraph and the proportional compasses are the readiest and most accurate methods of performing these reductions; but in the absence of these, many different methods are taught in works of practical geometry.

Reduction, Formulæ of. In the Integral Calculus, formulæ which serve to reduce given integrals to others of simpler forms. The following are useful examples of such formulæ:

$$\int x^{m-1}(a+bx^n)^p = \frac{x^m(a+bx^n)^p}{m} - \frac{npb}{m}\int x^{m+n-1}(a+bx^n)^{p-1}\,dx$$

$$\int \sin^p x \cos^q x\,dx = \frac{\sin^{p+1}x\cos^{q-1}x}{p+1} + \frac{q-1}{p+1}\int \sin^{p+2}x\cos^{q-2}x\,dx.$$

Definite integrals may often be greatly simplified by such formulæ, which are obviously deduced from the method of *integration by parts*. [INTEGRAL CALCULUS.]

Redundant Hyperbola. A line of the third order, having three pairs of asymptotic branches. Its properties may be seen in Newton's *Enumeratio*.

Redwing. [TURDUS.]

Reed (A.-Sax. hreod, Ger. ried). The common name for *Phragmites communis*, a waterside native plant widely distributed in other countries, and which was formerly (and is still by some) included in the genus *Arundo*. The name is applied also to other plants. Thus the Small-reed is *Calamagrostis*; the Aromatic-reed of Scripture is *Andropogon Calamus aromaticus*; the Egyptian-reed is *Papyrus antiquorum*, &c.

REED. In Music, a thin tongue of wood or metal (formerly made actually from a reed), which, being set in vibration by the action of wind, gives the sound to certain musical instruments, as the oboe, the clarionet, and the bassoon; as also in certain stops of the organ, in the harmonium, and the concertina. Sometimes the reed beats against its seat, and sometimes it is free, the latter variety being called the free reed.

Reef. A chain of rocks in the ocean lying near the surface. Coral reefs are reefs of coral brought close to the surface of the sea without rising much above the surface. [PHYSICAL GEOGRAPHY.]

REEF. In Navigation, *to reef* is to diminish the surface of the sails on the increasing of the wind. Sails attached to yards are reefed at the head. Strong horizontal bands of canvas, from three to six feet apart, extend across the sails; these are called *reef bands*, there are usually four in each topsail, and two in the foresail and mainsail. The reef band is commonly pierced with two holes in each cloth (or breadth of canvas) in the sail; through each hole are drawn two *reef points*—short pieces of flat rope, each having an eye in one end, and hung one before and the other abaft the sail, each passing through the eye in the end of the other. The sail being lowered and trimmed to the wind so as to shake, the extremities of the reef band are drawn up towards the *yard arm* by the ropes called *reef tackles*. The men then going out upon the yard, which they lean over while their feet are supported by the *foot ropes*, gather up the loose canvas of the sail till they reach the reef band, which they keep extended tight along the yard until the *earings* are *passed* or secured, the weather earing being passed first; they then tie the two reef points of each pair together over the yard, and the sail is reefed, the surface having been thus diminished by the depth of one reef. Gaff sails are reefed at the foot. The sail being lowered enough to slack the canvas, the earing on the after leech is brought or hove down to the boom end by a strong rope called a *reef pendant*; the men then standing wherever they can reach the foot of the sail, tie the points under it. When the yard is not lowered, as in reefing the courses, the sail is partly clued up for reefing.

Under Cunningham's patent, sails may be reefed or furled by ropes from the deck; an improvement of great importance, as reefing sails during tempestuous weather is attended with considerable danger to life. The action of this apparatus will be described under SAILS.

Reel (A.-Sax. reol). An angler's implement attached to the butt of the rod, for the purpose of winding in the line when a fish is hooked. The barrel of the reel should be of sufficient diameter to wind in quickly, as a fish is often lost from the inability of the angler to bring him rapidly within reach of the landing net; especially where, as in fly fishing, a great length of line has been thrown out.

REEL. A lively dance peculiar to Scotland, generally written in common time of four crotchets in a bar, but sometimes in gig time of six quavers.

Reeming Iron (Lat. rima, *a chink*). An iron wedge of very acute angle used by caulkers in forcing slightly apart the planks of a ship, in order that oakum may be driven between.

Reepers. Laths split from the stems of the Palmyra Palm, and used in the East for building purposes.

Reeve (A.-Sax. gerefa, *an officer* or *governor*). A word of very general application, entering into the composition of some titles yet in use. Hence *sheriff*, i.e. *shire-reeve*, the governor of a shire or county; *borough-reeve*, *port-reeve*, &c.

REEVE. In Ornithology. [RUFF.]

REEVE. The Sea term for passing a rope through any block or hole through which it is intended to run.

REEVE. In Zoology. [MACHETES.]

Reeving Tackle. Passing the ropes through the blocks in a system of pulleys.

Refection (Lat. refectio, from reficio, *I restore*). In the language of Ecclesiastical communities, a spare meal, sufficient only to maintain life; whence the hall in convents where meals are taken is termed *refectory*.

Refectory. [REFECTION.]

References (Lat. refero, *I bring back*). In Printing, marks carrying the eye from the text to the marginal or foot note. The most common are the *, †, ‡, §, ‖, ¶; but where there are more than six notes in a page, the neatest mode is to print small letters (^{a}) or figures (^{1}).

Referendaries (from Lat. referendus, *to be referred*). In the early monarchies of Europe after the fifth century, public officers charged with the duty of procuring, executing, and despatching diplomas and charters. The office of great referendary, in the French monarchy, became merged in that of chancellor.

Refikite. A mineral hydrocarbon forming tubercles and small veins of a wax-white colour, in Lignite, at the Abruzzi near Naples. Named after Refik Bey. Analogous to paraffine.

Refining. The process of separating gold from silver and copper. For this purpose the alloy is first melted and granulated by being poured in a fused condition into water. Between 200 and 300 kilogrammes of the granulated alloy are boiled in concentrated sulphuric acid in vessels of cast iron or platinum. The silver and copper of the alloy are thus converted into sulphates, the gold being unattacked. During this ebullition large quantities of sulphurous acid are evolved, which are conducted into the leaden chambers of the sulphuric acid factory, and there recovered in the form of sulphuric acid, which may be used for subsequent operations. When the ebullition with sulphuric acid is complete, i. e. after two or three hours, the mixture is allowed to stand for a short time, and the liquid poured off from the sediment of spongy gold. The mass is then washed with water, the washings being added to the liquid previously poured off, and the gold boiled once more with sulphuric acid. Even after this treatment the metal is not absolutely pure, but contains about 0·5 per cent. of silver, which may be removed by fusion with acid sulphate of soda. After the second ebullition with sulphuric acid, the gold is well washed with water, dried, and fused. The solution containing the sulphates of silver and copper is mixed with water, and gently heated with metallic copper. By this means the silver is precipitated, an equivalent quantity of copper passing into solution in the form of sulphate. The spongy silver is then separated from the excess of copper, well washed, dried, pressed by hydraulic power, and fused.

The solution of sulphate of copper is now evaporated to crystallisation, and the mother liquors, which contain large quantities of sulphuric acid, are employed in a future operation for the treatment of the original alloy.

For this process, which is termed the *parting of gold*, it is necessary that the alloy should not contain more than 20 per cent. of gold; otherwise the excess of gold protects the silver and copper from the action of the acid.

In cases in which the alloy is richer in gold, it is previously fused with a sufficient quantity of auriferous silver.

Alloys containing small quantities of gold and silver are first roasted, the oxide of copper formed in this manner being removed by means of dilute sulphuric acid, and the residue treated in the usual way.

Alloys containing as little as 0·05 per cent. of gold may be economically worked by this process of parting. Refined gold contains about $\frac{992}{1000}$ of pure gold.

Another process of gold refining, termed *quartation*, consists in fusing the alloy with three times its weight of silver, and boiling the granulated product with nitric acid, which removes the silver, leaving the gold in a porous condition. This process was at one time almost universally adopted for the refining of gold, but the low price of sulphuric acid renders the operation of parting the more economical one for use on a large scale.

The term *refining* is also applied to the purification on a manufacturing scale of other metals; of salts, as nitre and common salt; and of other bodies, as sugar, &c.

Reflecting Circle. An astronomical instrument for the measurement of angles by reflection. [SEXTANT.] The term is also applied to a surveying instrument, invented by Sir Howard Douglas, which combines the advantages of Hadley's quadrant and the protractor. The object of it is to protract, or lay down on the plan, the angles measured with the instrument from the instrument itself, without any intermediate step, or even a register of their values. The advantage of such an instrument must be obvious in military surveys, where expedition is important, while accuracy is thereby far more efficiently insured than by the old and more tedious process. It is also advantageously used in forming general sketches of a country.

Reflector. The name generally given to a reflecting telescope. [REFLEXION; TELESCOPE.]

Reflex (Lat. reflexus, part. of reflecto, *I bend back*). In Painting, the illumination of one body, or a part of it, by light reflected from another body. The foundation of the law of *reflexes* depends upon the knowledge that every body in light reflects that light, to a certain degree, in the same way that flame does. The stronger, therefore, the light on the body, the stronger will be the *reflex*, distances being equal. Again, the more directly the light falls on a body, the more influence it will have in imparting a reflex.

Reflex Function. In Physiology. [AUTOMATIC; MOTORY; SENSORY.]

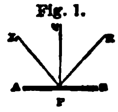
Reflex Zenith Tube. An instrument designed by the Astronomer Royal, and in use at the Greenwich Observatory, for measuring the zenith distances of stars very near the zenith. It consists mainly of an object-glass of 5 inches diameter and 10 ft. focal length; of a micrometer firmly attached to the cell of the object-glass; and of a trough of mercury placed beneath the object-glass at a distance of nearly half its focal length. The cell of the object-glass is fixed in a tube sliding in another tube fastened to the flooring of the small chamber in which the instrument is erected, the mercury being a short distance beneath the flooring. By this apparatus the parallel rays proceeding from a star very near the zenith are, while in a converging state, reflected from the mercury, so as actually to converge to a focus and form an image at a short distance above the object-glass; and it is ingeniously contrived that the point of convergence shall be in the same line (measured parallel to the diameter of the object-glass) with its focal centre. By this means any inaccuracy which would arise from a small error of level of the plane of the micrometer is avoided. A micrometer is mounted upon the cell which carries the object-glass, which has a series of

wires stretched across its side bars, and whose screw acts against the standards carrying the bars, the wires being placed at intervals nearly equivalent to double the distance of γ Draconis (the star which passes nearest to the zenith) from the zenith of Greenwich. For viewing the images of the star and the wires together, a compound 4-glass eye-piece is used, consisting of two distinct parts, the first part consisting of a first lens for receiving the rays from the object-glass, and a glass reflecting prism for turning them into a horizontal direction, the prism having one side ground to a spherical surface, so as to produce the effect of the second glass of the eye-piece, and to avoid unnecessary loss of light. This part is fixed in a tube carried between the bars of the micrometer. The second part consists of the third and fourth glasses of the eye-piece mounted in a tube carried horizontally by a fixed support, so as to allow the head of the observer to avoid interference with the rays after passing through the object-glass. The cell of the object-glass is made to revolve, carrying with it the micrometer, for the purpose of making observations in reversed positions. The micrometer is also double, carrying screws and divided heads on each side of the object-glass, and it is so arranged that by the action of one of the screws the micrometer wires are carried without disturbance of the reading of the head attached to the other screw.

Reflexion. In Mechanics, this word denotes the rebound or regressive motion of a body from the surface of another body against which it impinges. In Natural Philosophy, the term is applied to the analogous motions of light, heat, and sound, when turned from their course by an opposing surface. The laws of the reflexion of light form the branch of science called *catoptrics*; those of the reflexion of sound are sometimes called *cataphonics*. [SOUND.]

Reflexion of Light.—When we consider only the *direction* of the rays of light after being reflected from a polished surface, and leave its *quantity* or *intensity* out of view, the laws of reflexion are extremely simple. Suppose AB (fig. 1) to be a smooth polished surface, or mirror, and a ray of light proceeding in the direction LP to impinge on the surface at P, and to be reflected from it in the direction PR. Through the point P draw PQ a normal or perpendicular to the surface; then, adhering to the definitions adopted by most writers on optics, the angle LPQ is called *the angle of incidence*, QPR *the angle of reflexion*, the plane in which are the two straight lines LP and PQ is called *the plane of incidence*, and the plane determined by QP and PR *the plane of reflexion*. Now the two general laws of reflexion are these: 1st. The plane of reflexion coincides with the plane of incidence; or the three straight lines LP, PQ, and PR, are in one plane. 2nd. The angle of reflexion is equal to the angle of incidence, and on the opposite side of the normal. These laws

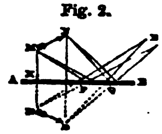
Fig. 1.



hold true, whatever be the nature of the reflecting surface, or the origin of the light which falls on it. Experience offers no exception to them whatever; and all the phenomena of reflection from mirrors or polished surfaces, whether plane or having any regular curvature, are readily deduced from them as simple geometrical consequences.

Reflexion from Plane Mirrors.—To determine the path of the reflected rays, and the formation of images by plane mirrors, suppose MN (fig. 2) to be an object placed before the plane reflecting surface AB, and the eye to be situated at E. The rays of light which proceed from the point M, and are reflected to the eye at E, will impinge on the mirror at P, and appear to come from a point m, which, in respect of the plane AB, is symmetrical with M; i. e. is placed in the straight line drawn from M perpendicular to the surface, and at the same distance from AB on the opposite side. For let MK be the perpendicular, and let it be continued till it meet the prolongation of EP in m: then, from the equality of the angles of incidence and reflexion, the angles MPK and EPB (which are the complements of those angles) are equal; hence $MPK = KPm$; and the two right-angled triangles KPM and KPm having also a common side, are every way equal; whence $Km = KM$. In like manner, the rays which issue from N, and are reflected to E, will appear to proceed from a point n symmetrical with N; and as the same thing is evidently true with respect to every other point of the object, a perfect image mn of the object will be formed on the opposite side of the mirror, and at the same distance. It will be observed that the image is not, properly speaking, reversed, like writing looked at through the opposite side of the paper: the spectator sees the same side of the object as if he stood in front of the mirror, and viewed the object directly; but, in the reflected image, right takes the place of left, and left of right.

Fig. 2.

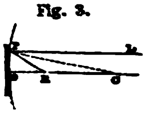


Reflexion from Curve Surfaces.—In order to apply the two general laws of reflexion to the determination of the direction of a ray reflected from a curve surface, it is assumed that the reflexion takes place at each point of the surface in the same manner as it would from a plane touching the curve surface at that point; and the problem therefore becomes that of determining the directions of the normal at the given point; for, when the directions of the incident ray, and of the normal at the point of incidence, are both known, the plane of the reflected ray, and the position of the ray in that plane, are both given. The mirror may be concave or convex; and the incident rays may be parallel or divergent.

Let D (fig. 3) be the centre of a concave mirror, DC its axis, C the centre of curvature at D; and assume the semidiameter of the mirror DP to be small in comparison of its

radius of curvature CD. Now suppose a ray of light LP, parallel to the axis, to fall on the mirror at P; then, if we draw PC, and make the angle CPR=CPL or PCD, PR will be the direction of the reflected ray; for, by the nature of curvature, CP is a normal to the surface, the arc DP being small. But, on the hypothesis of DP being small, we have also RP=RD; and by reason of the equal angles RPC and RCP, RP=RC, therefore RD=RC; or R is a given point, and, consequently, all the rays which fall on the mirror parallel to CD are reflected into the same point R. From this property the point R, which bisects the radius CD, is called *the principal focus* of the mirror, or *the focus of parallel rays.* [Focus.]

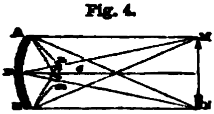
Fig. 3.



If the reflecting surface were a portion of a paraboloid, then all rays parallel to the axis would be accurately reflected into the focus at R, whatever the extent of the surface might be; but, on account of the practical difficulty of grinding and polishing curve surfaces of any other form than the spherical, the concave and convex mirrors required for optical purposes are often spherical.

From what has now been shown, it is easy to see in what manner images are formed by concave or convex mirrors. Let MN (fig. 4) be an object placed before a concave mirror AB, beyond its centre of curvature C. On tracing the path of the rays MA, MD, MB, after reflexion, they will all be found to meet in the point *m*, and those which proceed from N will in like manner be found to meet in *n*; whence rays diverging from every point of the object between M and N will meet, after reflexion, in a point situated between *m* and *n*: and in this manner an inverted image *mn* of the object will be formed. The magnitude of the image is to that of the object as D*m* to DM, or as the distance of the image from the mirror is to the distance of the object from the mirror; and the image will be more brilliant in proportion as the rays of light coming from the object are collected within a smaller space. If the object were placed at *mn*, then an enlarged image would be formed at MN. It is on this principle that reflecting microscopes and telescopes are constructed. [Microscope; Telescope.]

Fig. 4.



Intensity of reflected Light.—It has now been shown that the path of the reflected light can be determined in all cases with geometrical precision, when the form of the reflecting surface is known; but the case is very different when the question is to determine the quantity or proportion of the light which is thrown into a different direction by an opposing surface. The following laws, however, have been established by experiment: 1st. The quantity of light regularly reflected by non-metallic surfaces increases with the angle of incidence, but does not vanish entirely when that angle becomes 0. 2nd. In the case of metals the reflective power does not vary much with the angle of incidence, but it is greatest at small angles of incidence. 3rd. Bodies of different natures, placed in the same circumstances, reflect very different proportions of the incident light.

On this subject a great number of experiments were made by Bouguer, and more recently by Arago, Fresnel, Potter, and others. The following numerical relations are given by Bouguer: When a beam of light, the intensity of which is represented by 1000, falls upon water so as to make an angle of 0° 30′ with the surface, the intensity of the reflected light is represented by 721; at an angle of 15° with the surface, by 211; at an angle of 30°, by 65; and at an angle from 60° to 90°, by 18. Of 1000 rays falling upon a surface of glass, and making an angle of 5° with the surface, 543 are reflected; 300 when the angle is 15°; 112 when 30°; 25 when 60°, or above. Of 1,000 rays falling on a polished surface of black marble, 600 are reflected when the angle with the surface is 3° 15′; 156 when 15°; 51 when 30°; 23 when 60° and upwards. Silver surpasses all other metals in reflecting power. When the incidence is perpendicular, it reflects more than 900 rays per 1,000. (*Traité d'Optique.* See also the *Edinburgh Journal of Science* for 1830 and 1832.)

In order to produce reflexion in a greater or less degree, the only indispensable condition is, that light pass from one medium to another having a different refractive power. In passing through a perfectly homogeneous medium, no reflexion takes place; but whenever there is a change of medium (and this change may occur in the same substance by an inequality of density in the different parts, or a different arrangement of the particles), more or less reflexion takes place at the surface which separates the two media. Thus, in passing through the atmosphere, the solar light undergoes an infinite number of partial reflexions before it arrives at the earth, as every successive thin stratum of air, by reason of its increasing density, forms, as it were, a different medium. [Refraction, Astronomical.]

Bodies are visible only in consequence of rays irregularly reflected from their surfaces meeting the eye; for rays which are regularly reflected show only the luminous points from which they emanate, and not the surfaces on which they fall. If the lunar surface were as perfectly polished as a globule of pure mercury, the moon would present to us only a reflected image of the sun. [Light; Optics.]

Reform, Parliamentary. The changes effected in the House of Commons by the English, Scotch, and Irish Reform Acts of 1832 are specified under the head Parliament. The movement in favour of such reform began early in the reign of George III. In 1780, the duke of Richmond introduced in the House of Lords a measure of almost democratic character. This was followed (1783) by Mr. Pitt, whose

object was chiefly to emancipate the crown from the influence of the great families. No result, however, followed these attempts, and the change was effectually adjourned for many years by the French wars (1792 to 1815). In 1831, Lord John Russell brought in the English Reform Bill. It was negatived, and parliament dissolved by William IV. in April that year. The new parliament, which met in July, gave a decided majority to ministers. The measure passed the House of Commons in September. On October 7 the Lords threw it out. Early in the following year the contest was renewed, and the Lords finally gave way on the second reading, but renewed their opposition in committee. Ultimately they yielded to the threatening aspect of the country, and the pressure put on them by the suggestion of a new creation of peers; and the Reform Act passed on June 7, 1832. Measures for a still further extension of the franchise were introduced by the governments of Lord John Russell in 1852, of Lord Aberdeen in 1854, of Lord Derby in 1859, and of Lord Palmerston in 1860; but in each case failed or were withdrawn. For some years after 1860 the question appeared to excite little interest in parliament, but public attention was again directed to it during the general election of 1865, and in 1866 the government of Lord Russell introduced a bill for lowering the franchise, and later in the same session a bill for the redistribution of seats. The two bills were afterwards consolidated, but were not approved by the House, and their failure led to the resignation of the ministry. (Lord Russell, *English Government and Constitution*; Molesworth, *History of the Reform Bill.*)

Reformation (Lat. reformatio). An era in Political and Ecclesiastical History, when the doctrines and usages of the Roman church, then dominant throughout the Western states of Christendom, were first successfully called in question. This event is commonly dated from the year 1517, when Luther began to oppose the pope, and condemned the sale of indulgences. Mosheim assigns to it the date 1520, when Luther was excommunicated.

Prior to the Reformation, the pope claimed of divine right, and exercised, absolute authority over the whole Christian church, with the exception of those states and provinces in which the Eastern or Greek church was established. Not only was his authority regarded as supreme on subjects of doctrine and discipline, but his decisions were considered as infallible; and whoever ventured to question or gainsay them was liable to such canonical censures and temporal penalties as the canon law determined. The pope also laid claim to supremacy even in temporal things throughout the wide range of his religious authority; though the exercise of this supremacy was not always quietly submitted to, and was sometimes resisted with success. He regarded all parts of the world not inhabited by Christians as uninhabited, and parcelled out these countries to their Christian conquerors according to his sovereign pleasure. But while the absolutism claimed by the Roman pontiff was calculated to arouse jealousy and opposition, these feelings were greatly increased by other causes; such as the immoral lives of the clergy; the exorbitant wealth of the church; the great personal immunities of ecclesiastics, and their encroachments on the jurisdiction of the laity. These and similar circumstances, which the invention of the art of printing and the revival of learning had tended more thoroughly and widely to disclose, gradually prepared the public mind for a reformation.

According to the doctrine of the Roman church, all the good works of the saints, over and above those necessary for their own justification, are deposited, together with the infinite merits of Jesus Christ, in one inexhaustible treasury. The keys of this treasury were committed to St. Peter, and his successors the popes, who might, it was said, open it at pleasure, and by transferring a portion of this superabundant merit to any particular person for a sum of money, convey to him either the pardon of his own sins, or a release for anyone, in whose happiness he was interested, from the pains of purgatory. Hence the origin (which took place in the eleventh century) of the sale of *indulgences*. Pope Leo X., in order to raise contributions towards building the church of St. Peter at Rome, granted, in 1517, the right of promulgating those indulgences in Germany, together with a share in the profits arising from the sale of them, to the archbishop of Magdeburg. The archbishop employed, as his chief agent for retailing them in Saxony, one Tetzel, a Dominican friar, who assisted by the monks of his order executed the commission with great zeal, but with little discretion or decency; and, by disposing of them at a very low price, carried on for some time an extensive and lucrative traffic among the credulous and ignorant. The princes and nobles were irritated at seeing their vassals drained of their wealth to replenish the treasury of a profuse pontiff. Men of piety regretted equally the corruptions of the church and the delusions of the people. Even the most unthinking were shocked at the scandalous behaviour of Tetzel and his associates. But it was reserved for Martin Luther, a monk of the Augustine order, and at that time professor of theology at Wittenberg, effectually to expose the artifices of those who sold, and the simplicity of those who bought, indulgences. What motives first induced him to oppose this traffic cannot now be ascertained. It was not a novelty, as it had been practised throughout Christendom for several centuries. Some writers have imagined, though with what justice is not evident, that his opposition was founded in jealousy, because this gainful trade had not been conferred on the Augustinians, to whom he belonged, but on the Dominicans, a rival order. But whatever were his motives, his opposition at first was confined simply to the sale of indulgences.

His memorable theses, ninety-five in number, against this practice were affixed to the doors of the cathedral of Wittenberg, October 31, 1517; while from the pulpit he inveighed bitterly against the irregularities and vices of the monks who published indulgences, as well as against the abuse itself. The sentiments contained in his theses he proposed not as points fully established, or of undoubted certainty, but merely as subjects of enquiry and disputation; and to the whole he subjoined solemn protestations of his high respect for the apostolic see, and of his implicit obedience to its authority. No opponent appeared at the time prefixed. The theses spread over Germany with astonishing rapidity, and were everywhere read with the greatest avidity. Meanwhile Tetzel, in opposition to Luther, published counter-theses at Frankfort-on-the-Oder; and Eckius, a celebrated divine of Augsburg, endeavoured with others to refute Luther's notions. But this opposition was of little or no avail. Luther supported his views by arguments founded on reason or derived from Scripture, and his cause was found daily to gain strength.

Leo, naturally fond of ease and pleasure, paid little or no attention to the dispute that was thus raging in Germany, and at first despised it as a mere monkish squabble. But the tidings of Luther's rapid success, and the clamours of the ecclesiastics for aid and vengeance, at length roused him from his apathy. On August 21, 1518, he summoned Luther to appear at Rome, within sixty days, before the auditor of the chamber and the inquisitor-general, whom he empowered jointly to examine his doctrines and to decide concerning them. This was evidently an unjust tribunal; and through the influence of Frederick, the elector of Saxony, who was favourable to the new doctrines, and of others, the pope, having received a submissive letter from Luther himself, agreed to refer the hearing and determining of the cause to his legate in Germany, Cardinal Cajetan, a Dominican eminent for scholastic learning.

The reformer accordingly appeared before Cajetan, who, after some discussion, commanded him to retract his opinions; but Luther with his characteristic intrepidity declared that he could not, with a safe conscience, renounce opinions which he believed to be true, nor should any consideration induce him to do what would be so base in itself, and so offensive to God. The result was, that he was induced to withdraw secretly from Augsburg and return to Wittenberg; previously to which, however, he prepared a solemn appeal from the pope ill informed at that time concerning his cause, to the pope when he should be better able to judge respecting it. But so impatient were Luther's enemies at Rome, that even before the sixty days had expired he was there condemned as a heretic, Leo, in several of the briefs and letters, having stigmatised him as a child of iniquity, and as given up to a reprobate mind. But Luther was not to be deterred from teaching and promulgating his opinions both from the pulpit and through the press; and as every step taken by the court of Rome against him convinced him that Leo would soon proceed to the most violent measures, he had recourse to the only expedient in his power in order to prevent the effect of the papal censures. He appealed to a general council, which he affirmed to be the representative of the Catholic church, and superior in power to the pope, who, being a fallible man, might err, as St. Peter, the most perfect of all his predecessors, had erred. As the controversy advanced, Luther's views began to expand; and in his disputation with Eckius he went so far as to question the supremacy of the pope over the church, as well as the doctrines of purgatory, auricular confession, and absolution; and about the same time he published several treatises, in which he more openly expressed his dissent. Luther may now be said to have embraced the tenet which became henceforth the characteristic of his theology, namely, that Scripture is the only rule of faith and manners, and that this rule is to be interpreted by the exercise of private judgment. A step was at this period (June 1520) taken by the court of Rome fatal to the object which it had in view. The pope issued a bull condemning, as heretical and offensive to pious ears, forty-one propositions extracted out of Luther's works; all persons were forbidden to read his works on pain of excommunication; those who possessed a copy of them were commanded to commit it to the flames; and he himself, if he did not within sixty days publicly recant his errors and burn his works, was to be pronounced a heretic, excommunicated, and delivered over to Satan; all secular princes being required, under pain of incurring the same censure, to seize his person, that he might be punished as his crimes deserved.

This sentence excited more indignation than terror among the followers of Luther, and gave a fresh impulse to the spread of the new doctrines. In some cities the people violently obstructed the promulgation of the bull; in others, the persons who attempted to publish it were insulted, and the bull itself was torn in pieces and trodden under foot. Luther, after renewing his appeal to the general council, published remarks on the papal bull; and assuming a bolder tone, declared the pope to be that man of sin, or Antichrist, whose appearance is foretold in the New Testament. He declaimed against his tyranny and usurpations, and exhorted all Christian princes to shake off such an ignominious yoke. Nor did he stop here. As Leo had, in execution of the bull, appointed Luther's works to be burnt at Rome, the latter, by way of retaliation, assembled all the members of the university of Wittenberg, and with great pomp, in presence of a vast number of spectators, cast the volumes of the canon law, together with the bull of excommunication, into the flames; and his example was imitated in several cities of

Germany. This took place on the 10th of December, 1520; and on the 6th of the ensuing month the pope launched a second bull against him, by which Luther was finally expelled from the communion of the church. Thus separated from all connection with the see of Rome, Luther was enabled to attack with the greater success most of the peculiar papal doctrines, both theological and ecclesiastical; and thus laid the foundation of that reformation of religion which at first he never contemplated.

A spirit of enquiry having, by means of Luther's preaching and publications, and the procedure of the court of Rome, been excited in the public mind, the progress of the reformed doctrines was rapid and general, and threatened to embrace the whole of Germany, although the emperor Charles V. co-operated with the pope to check and destroy them. Luther, too, was protected, from various motives, not merely by the elector of Saxony, but by many other princes; and the new views were adopted and sedulously propagated by Melanchthon, Carlostadius, and other eminent men. Erasmus, too, though he did not long follow in the same course as the German reformer, and ultimately wrote against some of his views, yet discovered and exposed, with great learning and ability, many errors both in the doctrine and worship of the Roman church.

Under these circumstances was held the imperial diet at Worms (January 1521), to which the different princes were invited, in order to concert measures for checking the progress of the new doctrines which threatened to disturb the peace of Germany, and to overthrow the religion of their ancestors. An attempt to condemn him in his absence was frustrated by a majority of the members of the diet; and Luther, under a safe-conduct, was summoned to appear before them. He did not hesitate to attend; but neither threats nor entreaties could induce him to retract any of his opinions, or to consent to their being tried by any other rule than that of Scripture. He was allowed to leave the city in safety; but an edict was published in the emperor's name, after his departure, putting him under the ban of the empire. The circumstances, however, in which Charles was placed, the commotions in Spain, and the wars in Italy and the Low Countries, together with the prudent precaution of the elector of Saxony in concealing Luther in the castle of Wartburg, all concurred in preventing the edict being carried into effect. During his confinement his opinions continued to gain ground; and the Augustinians of Wittenberg ventured on an alteration in the established forms of public worship, by abolishing the celebration of private masses, and by giving the cup as well as the bread to the laity in administering the sacrament of the Lord's Supper. In a short time, however, the new views were condemned by the university of Paris, and a refutation of them was attempted by Henry VIII. of England. Luther published animadversions on both with as much virulence as if he had been dealing with an ordinary adversary.

Meanwhile an attack no less violent, occasioned by a similar cause, was made on the Roman church in Switzerland. The Franciscans being intrusted with the sale of indulgences in that country, executed their commission with the same indiscretion which had rendered the Dominicans odious in Germany. But they were met and opposed (1518) by Zuinglius, a man not inferior to Luther himself in zeal and intrepidity, and who advanced with perhaps more daring and rapid steps to overthrow the whole fabric of the established religion. Notwithstanding that the universities of Cologne and Louvain pronounced his doctrines to be erroneous, the cantons of Zurich, Berne, Basle, and Schaffhausen embraced his opinions. Several conferences were at different times held between the Roman Catholics and the *Evangelicals*, as the followers of Zuinglius were called; and all of them tended to the spread of the reformed faith. After a conference held at Berne in 1528, the council of that canton published ten theses, which embodied the substance of the Reformation in Switzerland.

The Swiss and the German reformers were at first unacquainted with the proceedings of each other, though both were animated by the same spirit. But, while they both resisted and exposed the usurpations and errors of the Roman church, and generally agreed in their sentiments, they entertained very different theological opinions; and thus were sown the seeds of those divisions which have since agitated the reformed churches. The chief subject of dispute between the two reformers was concerning the manner in which the body and blood of Christ were present in the Eucharist. Luther and his followers, though they rejected the papal belief of transubstantiation, were nevertheless of opinion that the body and blood of Christ were really present in the Lord's Supper, a doctrine repudiated by Zuinglius and his adherents. Both parties maintained their opinions with equal obstinacy; and as this dispute threatened to retard the great work of reformation, and to bring discredit on its adherents, the landgrave of Hesse invited Luther and Zuinglius to a conference at Marburg, in order to promote unanimity and peace. After a disputation of four days, however, neither of the contending parties could be persuaded to abandon their views. But as both agreed in their sentiments not only as to the popish hierarchy, but as to the fundamental principles of Christianity, they parted in Christian charity, though not in brotherhood, agreeing to refrain from open controversy.

The struggle between the Roman Catholics and the reformers still raged in Germany. At the diet of the empire held at Spires in 1526, the emperor's ambassadors used their utmost endeavours to suppress all disputes about religion, and insisted on the vigorous execution of the sentence which had been pronounced against

Luther and his followers at Worms. This attempt was successfully resisted by the majority of the members; and it was at last unanimously agreed to present an address to the emperor entreating him to call a general council without delay; and that the princes of the empire should in the meantime be allowed, in their respective dominions, to manage religious matters as they should think proper. These resolutions proved favourable to the cause of the Reformation. The war in which the emperor was at this time engaged with the pope gave a decided advantage to the friends of the reformed faith, and greatly increased their number. At a diet, however, held in the same place in 1529, the power which had been given to princes of managing ecclesiastical affairs until the meeting of a general council was revoked by a majority of votes, and every change declared unlawful that should be made in the established religion before the determination of the approaching council was known. After many ineffectual remonstrances and arguments, six princes of the empire and thirteen imperial cities *protested* against this decision. Hence arose the denomination of *Protestants*; a term at first applicable only to the Lutherans, but now common to all who have separated from the church of Rome.

As the reformed doctrines in Germany had not yet been reduced to a system, the elector of Saxony ordered Luther and other divines to commit to writing the leading articles of their system, along with the principal points on which they differed from the church of Rome. In compliance with this order, Luther delivered to the elector at Torgau seventeen articles, hence called the Articles of Torgau.

In 1530, Charles convoked a diet of the empire at Augsburg, and directed the reformers to lay before it an account of their tenets in German and Latin. The work prepared by Luther and Melanchthon, and presented to the diet, was hence called the Confession of Augsburg, or *Confessio Augustana*. It was read aloud by the chancellor to the assembly. It contained twenty-eight chapters, of which twenty-one were illustrative of the religious opinions of the Protestants, and the remaining seven of the errors and superstitions of the papal faith. After much disputation the diet published a decree condemning most of the peculiar tenets held by the Protestants, and forbidding any person to protect or tolerate such as taught them. But the Protestants were now too powerful a body to be easily dismayed. They assembled at Smalcalde, where they concluded a treaty of mutual defence, both religious and political, against all aggressors, and formed the Protestant states of the empire into one regular combination. Thus, in the year 1530, the Reformation was virtually established in Germany; first, by the publication of the Confession of Augsburg; and, second, by the league of Smalcalde, which made that creed the bond of union of a powerful political confederacy.

It may here be mentioned that the followers of Zuinglius, or Sacramentarians, as they were sometimes called, presented their confession of faith on the part of four cities, Strasburg, Memmingen, Lindau and Constance; generally known by the Confession of Strasburg, or *Confessio Tetrapolitana*. The reformed cantons of Switzerland were not allowed to join the league of Smalcalde, inasmuch as they refused to sign the Confession of Augsburg; and thus the Swiss Evangelicals or Sacramentarians continued distinct from the Lutherans (as they still do), though they joined in a separate league with the city of Strasburg and the landgrave of Hesse, who adopted their views. The Helvetic Confession of Faith, founded on the articles of Berne already referred to, was finally published in 1532. The reformed doctrines had early spread to Geneva; and John Cauvin, or Calvin, of that city, after the death of Zuinglius, carried them farther than the Swiss Protestants had done. He abolished all festivals except the Sabbath, discarded all church ceremonies, used leavened bread for the sacrament, and taught the doctrines of predestination and election in all their rigour. [PRESBYTERY.] Calvinism thus became the third great branch of the Reformation, Luther and Zuinglius being respectively at the head of the other two. The systems of Zuinglius and Calvin, however, gradually merged together, and they may now be considered as one, having the same confession of faith.

Among other results (such as conferences, meetings of councils, particularly the celebrated council of Trent in 1549) the treaty of Smalcalde gave rise to a war between the emperor and the Protestants. But the peace of Augsburg, in 1555, terminated these calamities, which had so long agitated the empire. The following are the leading articles of the peace: namely, that the Protestants who followed the Confession of Augsburg should in future be free from the jurisdiction of the pope; that all the inhabitants of the German empire should be at perfect liberty to judge for themselves in all matters, religious and ecclesiastical; that all persons, whatever be their religious opinions, should enjoy equal civil rights and privileges, and that all those who should persecute any person under religious pretences should be declared and treated as public enemies of the empire. Thus was the Reformation finally established in many parts of Germany as it exists, without any very marked change either as to its extent or its principles, at the present day. This state of things was broken many years after by the Thirty Years' War (1619–48); but the treaty of Westphalia, which terminated this war, confirmed the articles of the peace of Augsburg, and extended its benefits to the Calvinists as well as to the Lutherans.

While these events were taking place in Germany and Switzerland, the doctrines of the Reformation found their way partially into France, and also into Spain and Italy. Prior to Luther's death (1546), these doctrines had made many converts in the Netherlands; and in the time of Philip II. the 'Seven United

Provinces,' which separated from the rest, proclaimed liberty of conscience, and adopted the tenets of Calvinism, to which they have ever since adhered.

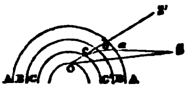
About the year 1556, the Lutheran creed was adopted as the state religion in Denmark and Norway. This creed was propagated in Sweden, soon after Luther's rupture with the church of Rome, by Olaus Petri, one of his disciples. Both Lutheranism and Calvinism early gained an extensive footing in Poland Hungary, and Transylvania. The Reformation in England did not extend to the hierarchical constitution of the church. In Scotland, episcopacy was rejected. [PRESBYTERY; COVENANTERS.] In Ireland, while the Protestant episcopal church is the established religion, more than three-fourths of the people retain their hereditary attachment to the papal creed. Altogether, not more than a fourth of the population of Europe are Protestant; of the remainder, about two-thirds still adhere to the Roman faith. The Protestant bodies predominate in the United States, and in almost all the British colonies. [CHRISTIANITY.] (Ranke's *History of Germany during the Reformation*; D'Aubigné, *History of the Great Reformation in Germany and Switzerland*; F. Paul, *History of the Council of Trent, &c.*; Burnet, *History of the Reformation*; Macaulay's *Essays, Von Ranke.*)

Reformatory. An institution for the reception and reformation of juvenile offenders under sentence for criminal offences. These appear to have originated in the efforts of philanthropic persons to establish places of refuge for such children after sentence. The statute 17 & 18 Vict. c. 86 first authorised the sending of children under sentence to these private foundations. But criminal courts are now, by 20 & 21 Vict. c. 55, enabled to sentence youthful criminals to detention in reformatories, which the magistrates of counties and districts are empowered to provide for this purpose, the parents being compellable, if able, to provide for their maintenance and education. Under later Acts, criminal or neglected children, not previously convicted of felony, may be sent for education and training to an *industrial* school (stat. 24 & 25 Vict. c. 113, &c.).

Refraction (Lat. refractus, *broken*). In Mechanics, the change of direction which takes place in the motion of a body when it passes obliquely out of one medium into another of different density. The term is chiefly applied to the deviation from their rectilinear course of the rays of light in passing through transparent substances.

Refraction, Astronomical. Refraction, in Astronomy, is the apparent angular elevation of the celestial bodies above their true places, caused by the refraction of the rays of light in their passage through the earth's atmosphere.

It is found by experiment that the refractive power of a gas, or aëriform substance, is proportional to its density. Now the earth's atmosphere is not a medium of uniform density, but of a density continually diminishing as the distance from the centre is increased. For the purpose of illustration, the atmosphere may be regarded as composed of a great but finite number of concentric spherical strata, each having a uniform density greater than that of the stratum by which it is enveloped, but less than that of the stratum which it envelopes. Hence, on entering each successive stratum the light must undergo a slight deviation from its rectilinear course, and the amount of all these deviations constitutes the phenomenon of astronomical refraction. Let A A, B B, C C, represent the boundaries of the successive strata, and suppose a ray of light proceeding from the star S to enter the highest stratum A A obliquely at a. If no deviation took place, the ray would continue to advance in the same straight line Sa; but in consequence of entering a denser medium it is refracted, according to the law of Descartes, into a direction ab, more nearly perpendicular to the surface of the spherical stratum. At b it again enters a medium of a greater density, and is refracted into the direction bc, still approaching the perpendicular to the surface. On arriving at c the phenomenon is repeated, and the ray is bent from the direction bc into the direction cO; so that in passing from S to O the ray of light, instead of describing the straight line SO, describes the polygon SabcO, and to a spectator at O the star will appear to be situated at S′ in the direction Oc. Hence the star appears to be elevated above its true place; and the angle S′OS, which is the difference between its true and apparent elevations, is the *astronomical refraction*. If we suppose the number of the strata to become infinitely great, then the angular deviation at each successive stratum will become infinitely small; and the path of the ray, instead of being a polygon, will be a continuous curve, which, according to the laws of refraction, will lie wholly in the same vertical plane.



Since the ratio of the sines of incidence and refraction is constant, it is evident that the total effect will be the greatest when the luminous rays enter the atmospheric strata with the greatest obliquity, i. e. when the object is seen in the horizon. At the zenith there is no refraction. In descending from the zenith to the horizon it continually increases, according to a certain law, which may be determined theoretically, if the refractive power of atmospheric air at a given density and temperature, the dilatation of air by heat, and also the law of the variation of the density and temperature in ascending into the higher regions of the atmosphere, are supposed to be known. At a medium density, and at the temperature of melting ice, Biot and Arago found by experiment that for any altitude exceeding 10° above the horizon the law of atmospheric refraction is represented by the formula

$$r = 60{\cdot}6'' \tan (Z - 3{\cdot}25 \times r),$$

in which r is the refraction corresponding to a given zenith distance Z. Bradley had given the formula

$$r = 57'' \tan (Z - 3{\cdot}25\ r).$$

From either of these it appears that the increase of refraction is nearly proportional to the tangent of the zenith distance, but at low altitudes the expression becomes much more complicated.

The following table, given by Mr. Ivory (*Phil. Trans.* for 1838, part 2), shows the amount of refraction at different zenith distances, the temperature being 50° Fahr. and the height of the barometer 30 inches. The correction (omitting some small terms) for the actual temperature and barometric pressure is obtained by multiplying the tabular refraction by $\dfrac{1}{1 + c\,(t - 50)} \cdot \dfrac{b}{30}$, where b is the observed height of the barometer reduced to the fixed temperature of 50° Fahr., t the temperature of the air on the same scale, and $c = {\cdot}002183$.

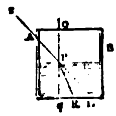
Zenith Distance	Refraction	Zenith Distance	Refraction
10°	10·30″	82°	394·68″
20	21·26	83	445·42
30	33·72	84	509·86
40	48·99	85	593·96
45	58·56	85½	646·21
50	69·52	86	707·43
55	83·25	86½	779·92
60	100·85	87	866·76
65	124·65	87½	971·93
70	159·16	88	1101·35
75	214·70	88½	1262·6
80	320·19	89	1466·8
81	353·79	89½	1729·5

The existence of astronomical refraction was known at an early period, though its amount and laws have been ascertained only in recent times. Ptolemy, in his book on *Optics*, remarks that in consequence of refraction a star is brought nearer the zenith, and that the effect is greater in the case of a low than a high star; but as no mention is made of the subject in the *Almagest*, we infer that it was not then regarded as an element of astronomical calculation. Similar notions appear in the *Optics* of Alhazen. Walther was the first who began to estimate the effects of refraction near the horizon; and Tycho Brahe constructed, from observations, the first table. He supposed the horizontal refraction to be 34′, which is very near the truth (its mean amount being 33′); but he supposed it to vanish at the altitude of 45°, though its mean amount at that altitude appears, by the preceding table, to be nearly 1 minute. Dominic Cassini gave an empirical formula for computing the refraction at any altitude; but the solution of the problem on true principles was first undertaken, and, in fact, fully accomplished, by Newton, though his results did not represent the observations, owing to the imperfect knowledge of that day respecting the physical constitution of the atmosphere. Our knowledge, indeed, as shown by Mr. Glaisher's recent balloon ascents, is at the present time by no means perfect.

Refraction of Light. The deviation of a ray of light from its original path in entering a medium of a different density. This change of direction, which takes place at the surface of separation of two media, is the ultimate fact from which many of the most interesting phenomena of light receive their explanation. The laws by which it is regulated, and the investigation of the consequences of those laws, form the branch of natural philosophy usually termed *dioptrics*.

The phenomenon may be observed as follows: Suppose a beam of light proceeding from a luminous point S (fig. 1) to be admitted through a small hole A in the side of a vessel A B: then, the vessel being empty, the light will fall on the bottom at a point L in the same straight line with S and A. Now let water be poured into the vessel, and suppose the beam of light to fall on the surface of the water at P; then it will be seen that the light no longer continues its course in the same straight line, but is bent, or *refracted* at P, and proceeds through the water in a straight line P R, more nearly perpendicular to the surface. A similar deviation takes place in all cases in which light passes from one transparent medium into another; but the magnitude of the angle RPL, or the amount of the refraction, varies according to the nature of the two media, and the degree of obliquity with which the incident ray falls on the surface of separation.

Fig. 1.



Through P draw QPq a normal to the surface; then SPQ is *the angle of incidence*, RPq *is the angle of refraction*, and the following laws are found to be observed in all cases:—

1. The refracted ray PR is in the same plane with SP and PQ; that is, with the incident ray and the perpendicular to the surface at the point of incidence.

2. The incident ray SP and the refracted ray PR are always on opposite sides of the perpendicular QPq.

3. Whatever be the inclination of the incident ray to the surface, the sine of the angle of incidence has to the sine of the angle of refraction a constant ratio.

The index of refraction of any transparent substance is the ratio of the sine of incidence to the sine of refraction, when light passes from a vacuum into the substance.

As there is no known substance of such a nature that light entering it from a vacuum is refracted so as to make the angle of refraction greater than the angle of incidence, the index of refraction is always greater than unity. Of all known substances, that which possesses the greatest refractive power is chromate of lead, for which the index of refraction is 3; hence in the equation $\sin i = n \sin r$, all the values of n which have yet been experimentally determined lie between 1 and 3.

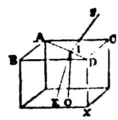
In the preceding remarks light has been regarded as a homogeneous substance, all the parts of which have the same index of refraction. This, however, is not the case; refraction never takes place without a separation of the different coloured rays, so that for every transparent body the index of refraction changes with the colour of the light. The numerical values of the indices, given in the above table, correspond to the yellow or green rays which occupy the middle of the dispersed pencil. For the different refrangibilities of the primary rays, see Chromatics; Dispersion; Spectrum.

Double Refraction.—The phenomena and laws of refraction, which have yet been considered, belong to those cases in which a single refraction takes place on the entrance of light into a different medium, or in which a pencil of light on entering a refracting medium continues to form a single pencil, and to afford a single image of the object from which it proceeds. There are, however, a multitude of substances which, either in their natural state or under accidental circumstances, exercise a peculiar influence on light, causing it, in its passage through them, to follow two distinct paths, forming with each other an angle of greater or less amount. Such substances are called *doubly refracting substances*, and the phenomenon itself is called *double refraction*.

The substances or media which produce only single refraction belong to one or other of the four following classes: 1. Gases and vapours. 2. Fluids. 3. Substances which have passed from the liquid to the solid state so rapidly as to prevent the molecules from taking a regular crystalline arrangement: for example, glass, glue, &c.; gums, resins, &c. 4. Crystals which belong to the regular system. All other substances, as the salts, precious stones, crystals not belonging to the above-named forms; all bodies belonging both to the animal and vegetable kingdoms, in which there exists any disposition to a regular arrangement of the molecules, as horn, mother of pearl, &c.; and in general all bodies unequally compressed, or which have not the same structure in all directions, separate the light which they refract into two distinct pencils, which pursue separate courses and are governed by totally different laws.

In order to give an idea of this remarkable phenomenon, let A B C D X (fig. 2) be a crystal of Iceland spar (carbonate of lime), having its faces made smooth either by cleavage or by grinding, and let it be laid on one of its faces on a sheet of white paper over a black spot O; then, on looking through the crystal, two spots will be seen, one at O, and the other at E. On turning the crystal round on its axis, but always keeping the same face on the paper, one of the images, O, will remain invariable, while the other, E, will appear to describe a circle about O. If instead of a round spot the object viewed be a straight line, then, on looking through the crystal, a double image of the line will be seen, one passing through O, and the other through E. On turning the crystal as before, it will be seen that the distance between the two lines varies, but that they always remain parallel to each other; and also that in the course of a complete revolution of the crystal about its axis there are two positions in which the images will coincide, and two other positions, midway between the former, in which they will attain a maximum distance. These phenomena show that a ray of light, S I, on entering the face of the crystal at I, is separated by refraction into two pencils, I O and I E; and it is found that on emerging from the crystals the two pencils make the same angle with the surface, and continue their course in a direction parallel to each other and to the incident ray S I.

Fig. 2.



If we cause a beam of solar light to fall on the crystal, and examine the paths of the two pencils, it will be found that I O follows the laws of ordinary refraction, the sine of incidence being to the sine of refraction in a constant ratio, and the pencil continuing in the same plane with the incident ray and the normal to the surface at the point of incidence; hence I O is called the *ordinary* pencil. But I E is found to follow an entirely different law, and is therefore called the *extraordinary* pencil.

If, for example, the incident ray S I is perpendicular to the face of the crystal, the ordinary refraction does not take place, the angle of incidence being zero; but in this case the angle of refraction of the extraordinary pencil, I E, is 6° 12′, and it is not in the same plane with the normal and the incident ray.

From a careful examination of the phenomena it is also found that although a ray of light falling on the face of the crystal is refracted generally into two pencils, there is one particular direction in which the incident ray undergoes only the ordinary refraction. This direction is parallel to A X, the shorter axis of the crystal, and is called the *axis of double refraction.* It is, therefore, to be observed that the axis of double refraction of a crystal is not a fixed line, but a determinate direction with reference to the faces of the crystal, every line parallel to A X forming an axis of double refraction. In some crystals the extraordinary ray is refracted *towards* the axis A X, in others it is refracted *from* it. In the first case the axis is called a *positive* axis of refraction; in the second it is called a *negative* axis.

In the crystal which we have now been considering (Iceland spar), there is only one direction in which the double refraction does not take place, but in many other crystals there are two directions which have this property. In examining the phenomena of double refraction in a great number of crystallised substances, Sir David Brewster found that all those crystals whose primitive and simplest form has only one axis of figure, or one pre-eminent line about which the figure is symmetrical, have only one axis of double refraction. The primitive forms which have only one symmetrical axis of figure are the following:—

1. The rhomb with an obtuse summit; as Iceland spar, tourmaline, quartz, &c.
2. The rhomb with an acute summit; of which form are corundum, sapphire, ruby, cinnabar, and arseniate of copper.
3. The regular hexahedral prism; as emerald, beryl, arseniate of lead, &c.
4. Octahedron with square base; as zircon, oxide of tin, prussiate of potash, &c.
5. Right prism with square base; as arseniate of potash, phosphate of magnesia, &c.

In all these forms, and in the primitive forms to which they belong, the line A X is the axis of figure and of double refraction; and it is the only direction in which there is no double refraction. (Brewster's *Optics*, p. 149.)

The property of possessing two axes of double refraction was discovered in 1815 by Sir David Brewster, who found that it belonged to all crystals, whether chemical bodies or mineral substances, which are included in the prismatic system of Mohs, or whose primitive forms are—

1. A right prism, base a rectangle.
2. A right prism, base a rhomb.
3. A right prism, base an oblique parallelogram.
4. Oblique prism, base a rectangle.
5. Oblique prism, base a rhomb.
6. Oblique prism, base an oblique parallelogram.
7. Octahedron, base a rectangle.
8. Octahedron, base a rhomb.

In all these forms there is no axis about which the crystal is symmetrical.

In all cases of crystals with two axes of double refraction, both the pencils are refracted according to the laws of extraordinary refraction. In a substance called analcime, Sir D. Brewster found that there were several planes along which if the incident ray passes it will not suffer double refraction, whatever be the angle of incidence. Each of these planes, therefore, may be considered as containing an infinite number of axes of double refraction, or lines in which there is no double refraction. No other substance has yet been found possessing the same property. (*Optics*, p. 155.)

Another very remarkable property is, that in crystals which have only one axis of double refraction the axis has always the same position, being, in fact, in all cases, the axis of symmetry; but in crystals which have two axes of double refraction, the axes change their position according to the colour of the incident light. Sir John Herschel, to whom this discovery is due, found that in crystals of Rochelle salt the inclination of the two axes for violet light is 56°, while for red light it is about 76°. In other crystals, as nitre, the inclination of the two axes is greater for the violet than for the red rays; but in all cases the line which joins the extremities of the axes for all the rays is a straight line.

The property of double refraction was discovered by Bartholin, in 1669, and was first explained by Huygens on the hypothesis of the propagation of light by means of an elastic medium. The phenomena have been studied with great assiduity in modern times, and, in fact, the investigation of their laws forms one of the principal parts of physical optics, and has mainly contributed towards the establishment of the now generally received theory of undulation. For the complete explanation of all the phenomena, the undulatory theory requires two postulates, or assumptions: 1. That the vibrations of the ether take place *transversely*, or in the direction perpendicular to the visual ray; and, 2. That the elasticity of the medium is unequally developed in the interior of the refracting crystal. The first of these assumptions is analogous to the effect of a blow given to a cord tightly stretched; the motion is communicated rapidly in the direction of its length, while the vibrations are at right angles to that direction. With respect to the second assumption, the facts which are known respecting the constitution of crystals render it exceedingly probable, à priori. All diaphanous bodies which refract light only in a single direction, and according to the Cartesian law, are found to have the same tenacity and the same elas-

ticity in all directions, and their linear dilatations by heat are also the same; but it has been established that with respect to all crystallised substances, which possess the property of double refraction, the elastic force with which they resist compression is greater in certain directions than in others, and also that the linear dilatation corresponding to the same increase of temperature varies with the direction in which it is measured. These facts prove that the matter of the crystal possesses an elasticity varying with the direction; and it seems natural to suppose that the ether within it must have the same property. On these two assumptions, namely, transverse vibrations, and unequally developed elasticity of the medium, Fresnel has constructed a mathematical theory of double refraction from which all the phenomena which have yet been observed are deduced as simple corollaries. (Sir J. Herschel's 'Treatise on Light,' *Ency. Metropol.*; Airy's *Mathematical Tracts*, 2nd ed.; Pouillet, *Élémens de Physique.*)

Refraction, Terrestrial. Atmospherical refraction [REFRACTION, ASTRONOMICAL] is the effect produced by the whole atmosphere on a body placed entirely beyond it; but as the density of the atmosphere varies with the height, it is evident that the apparent place of any object placed on a different level from that of the observer must be affected in a greater or less degree by refraction. Whether the rays of light come from a more elevated object and consequently pass from a rarer into a denser medium, or from an object depressed below the horizon of the observer and consequently pass from a denser into a rarer medium, they are equally bent downwards, and thus the apparent place of the object is raised. This refraction between terrestrial objects is called *terrestrial refraction*; and as the density of the air near the surface of the earth is liable to great irregularities from being irregularly heated, its effects give rise to many very remarkable phenomena. Among these are LOOMING or MIRAGE, the FATA MORGANA, and the occasional appearance above the horizon of distant objects which in the ordinary state of the atmosphere are invisible. Sometimes, in consequence of the rarefaction of the air in the neighbourhood of a surface of water, or of a building, or of the earth itself, a distant object appears to be depressed instead of being elevated; and occasionally it is at once both depressed and elevated, so as to appear double, in which case one of the images is generally seen in an inverted position, as if a reflexion had taken place. In very exact observations, as in geodetical surveys, it is found that the refraction is not always confined to the same vertical plane, but sometimes produces a deviation amounting to a few seconds laterally.

Refractive Power. In Optics, the degree to which a diaphanous body deflects a ray of light which passes through it. For the measure of this influence modern writers generally adopt the square of the index of refraction diminished by unity, or n^2-1, where n denotes the principal index of refraction. [REFRACTION.]

Some modern authors employ the phrase *absolute refractive power* to denote the ratio of the refractive power of a substance (as above defined) to its density; that is to say, the ratio $(n^2-1):D$, where D stands for the density of the body.

The French authors use the term *puissance réfractive* to denote the refractive power, or the number n^2-1, while they express the *absolute refractive power*, or the ratio $(n^2-1):D$, by the term *pouvoir réfringent*. It is convenient to have different names for the two things, which are totally different, at least in their numerical measures. Thus hydrogen gas has a smaller index of refraction, and consequently a smaller refractive power, than any other substance; but its *absolute refractive power*, or *pouvoir réfringent*, is greater than that of any other substance. (For a table of the values of the ratio $(n^2-1):D$ for a considerable number of different substances, see Brewster's 'Optics,' *Cabinet Cyclopædia.*)

Refractor. The name generally given to the refracting telescope. [TELESCOPE.]

Refractory Minerals. Such minerals as can bear exposure to great heat without change or injury. The most important of these are Mica, Graphite or Plumbago, Steatite or Soapstone, Potstone, Pyrallolite, Fire-clay, some kinds of sandstone, &c.

Refrain (Fr. refrein). The burden of a song, &c. [BOURDON.]

Refrangibility (Lat. re, and frango, *I break*). In Optics, the disposition of the rays of light to be refracted or bent in passing obliquely from one transparent medium into another. The term is chiefly used to denote the degree of that disposition possessed by the differently coloured rays. [REFRACTION; SPECTRUM.]

Refresher. In Law, an additional fee paid to counsel when a cause is not heard in the term for which it was originally set down.

Refreshment Houses. In Law, houses kept open at night for public refreshment or entertainment, but not licensed for the sale of beer, cider, wine or spirits. They are placed under special regulations by stat. 23 Vict. c. 27 and subsequent Acts.

Refrigerator (Lat. refrigero, *I make cool*). A term sometimes applied to a system of pipes contained in tanks of cold water, and used for the cooling of large quantities of liquids, which are made to circulate through the pipes. More usually, however, the word is used as synonymous with CONDENSER.

Refuge, Cities of. Six cities mentioned in the Pentateuch as appointed for the reception of those who had caused the accidental death of anyone. It is stated that if a deliberate murderer should flee to one of these cities, the elders of the city are to deliver him 'into the hands of the avenger of blood.' (Deut. xix.; Josh. xx.)

Refugee. A name which has been given indiscriminately to persons who flee from religious or political persecution in their own country, and take refuge in another. It was originally applied to the French Protestants (réfugiés) who found an asylum in this country and in others after the revocation of the Edict of Nantes by Louis XIV.

Regalia (Lat. *royal things*). In English Heraldry, the royal insignia, crowns, sceptres, globes, crosses, &c. used at the coronation: also the crown jewels.

REGALIA. In Politics, the privileges, prerogative, and right of property, belonging in virtue of office to the sovereign of a state. The latter class of objects are most commonly termed *regalia minora*, as, in some countries, waifs, strays, and newly-formed land, &c.; in England, forfeitures, &c.; while the former are known by the epithet *majora*.

Regalia of the Church. The privileges which have been conceded to it by kings; sometimes the patrimony of a church.

Regardant (Fr.). In Heraldry, literally *looking behind*; applied to any animal whose face is turned towards the tail in an attitude of vigilance.

REGARDANT. In Law, a *villein regardant* was probably so called because annexed to a manor regarding or relating to it.

Regarder. The obsolete title of an officer whose duty it was to overlook a forest. [RANGER.]

Regatta (Ital.). A word used originally by the Venetians to signify a grand fête, in which the gondoliers contested for superiority in rowing their gondolas; but the term has been adopted into all the languages of modern Europe, in which it signifies a brilliant species of boat race.

Regel or **Rigel.** A star of the first magnitude, in the left heel of the constellation Orion.

Regenerating Furnace. A furnace lately introduced, which acts by causing the products of combustion, on their way to the stack or chimney, to pass over an extended surface of brick, metal, or other suitable material, capable of retaining heat, which afterwards serves to heat the atmospheric air, or other materials of combustion, in such manner that the cold air is first brought into contact with the more intensely heated portions, until it finally passes the surfaces nearest the place of combustion, which are consequently heated to the highest point. Usually four chambers filled with firebrick are employed, one pair receiving the waste heat while the other pair, previously heated, are giving up their acquired heat to the gaseous fuel and to the air required for burning it. The direction of the currents is changed by a simple system of reversing valves. The regenerative furnaces are largely applied in the operations of the glass blower and plate-glass maker, in the pottery and porcelain factories, also in puddling and welding iron, and cast-steel melting. Attempts have been made to introduce them in gas-works, and they appear to be very successful in all cases where intense heat combined with a regularity of draught is attainable. The best description of this kind of furnace is to be found in Mr. Siemens' patent; and the *Practical Mechanic's Journal* for October 1, 1864, contains a good account of the application of the principle to the burning of bricks.

Regeneration (Lat. regeneratio). In Theology, this term is used to denote the new birth of man unto righteousness, following on the abolition of the original corruption of his nature. Similar language was used respecting the admission of proselytes to the privilege of Judaism: so, also, in other religions. The Sanscrit name for a Brahman is said to signify *twice born*; and Tertullian says that the heathens used baptism in their mysteries, *in regenerationem*.

Regent (Lat. rego, *I govern*). The person who exercises the powers of a sovereign during the absence, incapacity, or minority of the latter. In most hereditary governments the maxim is, that this office belongs to the nearest relative of the sovereign capable of undertaking it; but this rule is subject to many limitations. The kings of France exercised at various periods the power of fixing, by ordinance or will, the regency, in case of their decease leaving issue under age; and also the period of their son's majority. Nevertheless, these wills have been at various times disregarded in favour of what was esteemed the principle of the monarchy. Thus, the testament of Louis XIII., by which he declared his wife future regent, but limited her power in the essential prerogative of the choice of a council, was set aside as to this limitation, and she was appointed regent with full prerogatives. The testament of Louis XIV., as to a regency during the minority of Louis XV., was set aside by the parliament of Paris immediately after his death. In England, the right to appoint the regent is now fully recognised to belong to parliament; although, in 1788, on the occasion of the first illness of George III., much discussion took place as to the absolute right which some supposed to inhere in the heir apparent.

Regent Masters or **Regents.** In the English Universities, a term borrowed from the ancient usages of the university of Paris. In that institution graduates in the faculties, within a certain period after their degree, had the privilege, which they were bound to exercise, of giving public lectures (docendi, legendi, regendi scholas). The same custom was adopted at Oxford and Cambridge; although the regent masters were at an early period succeeded in the performance of this office by the established professors. [MASTER OF ARTS.]

Regicide (Lat. rex, *king*, and cædo, *I kill*). The offence of slaying a king or other sovereign. The early Greek republics, unaccustomed to the legitimate rule of monarchs, saw, in the occasional subjugation which they underwent from successful partisans, a mere usurpation,

or tyranny; and tyrannicide was with them only the slaying of a public enemy. The ancient Greeks made a wide distinction between hereditary sovereigns, whether constitutional or despotic, and those who had risen to absolute power by subverting an existing free constitution. With them the former was an object of respect, and was regarded as having a right to the obedience of his subjects; the latter was in their eyes simply as a wild beast who had burst into the fold of civil society, and whom every citizen was bound by whatever means to destroy. (Arnold, *History of Rome*, i. 476.) The hatred which grew up in the minds of the Roman people to the royal name and authority made them regard the acts assigned by tradition to the elder and younger Brutus, even to the latest days of the republic, and long after the establishment of the empire, as virtuous and honourable. Hence arose a perverted morality on this peculiar subject, which continues to prevail, more or less, even to the present day, as false in logic as contrary to the plain rules of conscience; for it is obvious that, to each individual, any wealthy or powerful oppressor, who commits injuries against him and his friends for which the law can give no redress, is just as fair a subject for illegal vengeance as a king to any member of the community. Yet no one ever sought seriously to set up the right of assassination in such cases; as Buchanan, Languet, Mariana, and others have done in that of kings. English history has three notorious instances of kings (Edward II., Richard II., and Edward V.) murdered by powerful and rebellious subjects. In France, Henry III. and IV. both fell by the hands of Roman Catholic zealots. But the savage execution of Ravaillac did not deter Damien, in the reign of Louis XV., from attempting the same offence from the same motives. The murder of the duc de Berri, and the repeated attempts on the life of Louis Philippe, from political enthusiasm, together with well-known recent instances, show but too plainly that the morbid passions which actuated these celebrated assassins have but taken in modern times another direction. The murder of Gustavus, king of Sweden, by Ankarström, is, perhaps, the most deliberate instance of this crime on record; for the criminal, though rancorous and determined, was no zealot. It must be added, that the application of the term *regicide* to the members of the commission which sat in judgment on Charles I., and to the majority of the convention which condemned Louis XVI., is a violation of that moral sense which judges unerringly of actions; whatever the character of their conduct might be, it was altogether different from assassination; and to confound Vane or Carnot with Ravaillac and Fieschi, under a similar designation, can serve no ends but those of temporary party malice. By the law of some continental countries, regicide is punished as PARRICIDE. (Hallam, *Literary History*, part ii. ch. iv. §§ 29-40, and part iii. ch. iv. § 2.)

Regifugium (Lat. *the king's flight*). A festival celebrated by the Romans to commemorate the expulsion of Tarquin the Proud. It is, however, doubtful whether the institution of this feast has anything to do with the flight of Tarquin; and the symbolical flight of the *rex sacrorum* from the Comitium after performing his sacrifice has been alleged as accounting for the origin of the tradition.

Regiment (Lat. rego, *I rule*: the Latin regimentum, like regimen, denoted *rule* or *authority*, and the word was used in this sense by Knox when he denounced the 'monstrous regiment of women'). A body of troops consisting (if infantry) of one or more battalions or (if cavalry) of several squadrons, under the command of a colonel. The royal regiment of artillery consists of thirty-one brigades, six of which are *horse brigades*. The British army consists at present (1866) of three regiments of life and horse guards; twenty-eight regiments of cavalry, of which ten are dragoons, thirteen hussars, and five lancers; three regiments of foot guards, divided into the Grenadier guards, the Scots fusiliers, and the Coldstream guards; and one hundred and nine regiments of infantry exclusive of the rifle brigade, besides ten colonial regiments and corps, the native troops in India, artillery, engineers, military train, marines, &c. Many of the regiments in the British army are distinguished by the name of the counties or districts where the men were originally enlisted. Thus the 3rd regiment is called the East Kent regiment; the 6th the Royal Warwickshire, &c. &c. No rule is established with regard to the number of men of which a regiment should consist: both in England and on the Continent this point is settled either by the exigencies of service in time of war, or the principles of economy in time of peace. [ARMY; ARTILLERY; CAVALRY; INFANTRY.]

Regin. In Mythology. [SIGURDR.]

Register, Lord, or Lord Clerk Register. A Scottish officer of state, who has the custody of the archives; hence also termed *custos rotulorum*. He was formerly the principal clerk of the kingdom, from whom other clerks derived their authority. The office since 1777 has been held for life. It is now merely honorary, the salary having been abolished in 1861, and the duties being performed by the registrar-general and depute clerk register.

Registrar (Low Lat. registrarius) The keeper of a registry. Many officers with this title exercise different functions in the Courts of Bankruptcy, Chancery, &c.

Registration of Title to Land. [TITLE.]

Registry of Births, Marriages, and Deaths. Down to the year 1836, in consequence of the defects of the system of registration, no complete or accurate information could be obtained as to the number of births, marriages, and deaths throughout England; but at that period the need of a better system was admitted, and the change was finally ac-

complished by the Act 6 & 7 Wm. IV. c. 86. [MORTALITY, BILLS OF.]

This Act, passed in pursuance of the recommendation of a committee of the House of Commons on parochial registers (1833), embodies a plan for the effectual registration of births, deaths, and marriages in England and Wales. To give uniformity to the system, it is conducted under the superintendence of an officer resident in London; and there also a central place of deposit is provided for certified copies of all parochial registers, with ready means of finding any entry in them. It is provided that in every case of *birth* the following circumstances shall be recorded: viz. the time and place of birth; the name (if any) and sex of child; name and surname of father; name and maiden surname of mother; rank or profession of father; the signature, description, and residence of the informant; and also the baptismal name of child, if added after registration of birth. In every case of *death* the register is to record the time and place of death; the name and surname, sex, age, and rank or profession of the deceased; *the cause of death*; and the signature, description, and residence of the informant. In all cases the entries must be signed by the informant, and also by the registrar, who discharges this duty without any immediate expense to the parties requiring registration, his remuneration being derived from moderate fees paid out of the poor's rates. The insertion of the cause of death, along with the period of death, and the residence, sex, age, and occupation of the deceased, will, in time, afford data of the utmost importance to medical science, and to the improvement of vital statistics.

The central office in London for the deposit of certified copies of registers, and the general supervision and conduct of the business of registration, is called the General Register Office. It is presided over by a registrar-general appointed under the great seal, having under him an assistant registrar, chief clerk, and a numerous body of subordinate clerks. From this office communications emanate to all superintending registrars, registrars of births and deaths, and registrars of marriages, who all act within their respective districts under the directions of the registrar-general, in whom is vested the power of dismissal.

There are upwards of 600 superintendent registrars, who may each appoint a deputy, with the approval of the registrar-general. Each superintendent registrar serves within the district to which he is appointed, which comprises one or more registrar's districts.

There are upwards of 2,000 registrars of births and deaths, who may each appoint a deputy, with the approval of the guardians, or of the poor law commissioners. Each registrar is appointed to some one of the registrars' districts, into which the whole of England and Wales has been divided; and he must reside in that district and register *all* births and deaths that occur in it.

Marriages are registered, 1st, By clergymen of the established church, of whom about 12,000 have been furnished with books for this purpose. 2ndly, By registrars of marriages, of whom there were, on the 1st of January, 1850, about 1,000: these last are appointed by the superintendent registrars, and register marriages solemnised in their presence in registered places of worship, or in the superintendent registrar's office. 3rdly, By the registering officers of Quakers. And 4thly, By the secretaries of synagogues.

The clergymen and the various officers, amounting in all to about 15,000, to whom the business of registration is committed, are bound to make quarterly deliveries of *certified copies* of all entries in their respective registers during the previous quarter, to the superintendent registrars of the district to which they respectively belong; and these certified copies are transmitted by the superintendent registrars to the registrar-general. The certified copies are made on separate leaves of paper of a uniform size and peculiar texture, having a distinguishing water-mark. On being received at the general register office in London (whither they are sent by post), they are carefully examined; and any defects, which may be noted, are made the subject of communication with the person from whom the defective copy came, and who is required either to furnish another copy or a satisfactory explanation. They are then arranged, paged, and inserted in books for reference.

Alphabetical indexes of births, deaths, and marriages are prepared and kept in the general register office; and any person, on payment of 1*s*., may search these indexes for any entry, and on finding it, may, if he wish, obtain, for 2*s*. 6*d*., a stamped copy of such entry, which will be 'received as evidence of the birth, death, or marriage to which the same relates, without any further or other proof of such entry.' There are separate alphabetical indexes for the births, the deaths, and the marriages in each quarter. The registrar-general is bound to furnish, once a year, to one of the principal secretaries of state a *general abstract account* of the births, deaths, and marriages registered during the foregoing year, to be laid before parliament. The first of these was prepared in 1838. They have since been continued with various improvements; and in a statistical point of view, the sound, accurate, and judicious information which they embody, cannot be too highly appreciated. (*Stat. of the Brit. Empire*, vol. i. pp. 410–430.)

The Act 6 & 7 Wm. IV. c. 86 does not extend to Scotland or Ireland, but similar provisions have been recently enacted for both these portions of the empire (7 & 8 Vict. c. 81, 26 & 27 Vict. c. 11, c. 90, for Ireland; 17 & 18 Vict. c. 80 &c. for Scotland).

Registry of Deeds. In Law. In England conveyances (including wills) of land situate in the three ridings of Yorkshire, or in Middlesex, must be registered according to the provisions

of certain special Acts of Parliament. This does not extend to copyhold estates, or to leases not exceeding twenty-one years in possession. The intention of the registry was to give notice, to purchasers, of incumbrances existing on estates; but its value, in this respect, is materially lessened by the prevalence of the equitable doctrine of *notice*; namely, that where a party is, either actually or constructively, aware of incumbrances not registered, he is bound by such knowledge. In Ireland and Scotland, and in most of the colonies, if not in all, there is a general system of registry, and many unsuccessful attempts have been made to induce parliament to establish a similar system for the whole of England.

Registry of Ships. [SHIPS, REGISTRY OF.]

Registry of Title. [TITLE.]

Regium Donum (Lat. *royal gift*). An annual grant of public money for the maintenance of the Presbyterian clergy in Ireland. It was instituted by William III. in 1690, and remodelled in 1790. The stipends are paid to ministers both of the Synod of Ulster and the Seceding Synod.

Regius Professor. The name given to those professors in the English universities whose chairs were founded by Henry VIII. In the Scotch universities, in which the patronage of by far the greater number of chairs is vested in the civil bodies, those professors are called regius professors who have been appointed by the crown.

Reglet (Fr.). In Architecture. [FILLET.]

REGLET. In Printing, a sort of furniture of an equal thickness throughout its length, and of quadrat height. The length is three feet, and the thickness that of the various sizes of types.

Regma (Gr. ῥῆγμα, *a fracture*). One of the terms applied to a tricoccous fruit, like that of the Castor-oil plant and the *Euphorbias*.

Regrating. [FORESTALLING.]

Regression (Lat. regressio, *a going backwards*). In Astronomy, the *regression of the moon's nodes* is the motion of the line of intersection of the orbit of the moon with the ecliptic, which is retrograde, or contrary to the order of the signs. This motion of the nodes of the lunar orbit takes place with considerable rapidity, the whole revolution being accomplished in about eighteen and a half years. The nodes of the planetary orbits also regress on the ecliptic; but, in the case of the planets, the regression is extremely slow, that of the nodes of Mercury, which is the most rapid, amounting only to about 42 seconds of a degree in a solar year. [NODE; PLANET.]

Regression, Edge of. [CUSPIDAL EDGE; EDGE OF REGRESSION.]

Regular (Lat. regularis, *according to rule*). In Botany, a term applied to flowers which have all the parts of each series of a similar form and size. Thus the Buttercup is regular, while the allied Larkspur is irregular.

Regular Clergy. [REGULARS.]

Regular Polygon. In Geometry, a plane rectilineal figure with equal angles and sides. [POLYGON.] It is always possible to describe a circle whose circumference shall pass through all its corners or touch all its sides. [INSCRIBED AND CIRCUMSCRIBED FIGURES.] If a be the side of a regular polygon of n sides, then the radii of its *circumscribed* and *inscribed* circles are, respectively,

$$\frac{a}{2\sin\frac{\pi}{n}} \text{ and } \frac{a}{2\tan\frac{\pi}{n}},$$

and its area is $\frac{a^2}{4}\frac{n}{\tan\frac{\pi}{n}}$.

Regular Polyhedron. In Geometry, a polyhedron whose faces are all equal and similar regular polygons. There are only five such solids, and these, from their discoverer Plato, are sometimes called also the PLATONIC BODIES. [POLYHEDRON.] If n be the number of sides, each equal to a, which form each face, and m the number of plane angles which meet at each corner of the regular polyhedron, then the inclination θ of any two adjacent faces is given by the formula—

$$\sin\frac{\theta}{2} = \frac{\cos\frac{\pi}{m}}{\sin\frac{\pi}{n}},$$

the radius of the inscribed sphere is equal to

$$\frac{a}{2}\frac{\tan\frac{\theta}{2}}{\tan\frac{\pi}{n}},$$

and the radius of the circumscribed sphere is equal to

$$\frac{a}{2}\tan\frac{\theta}{2}\tan\frac{\pi}{m}.$$

The area of the surface is, of course, easily found from that of one face [REGULAR POLYGON], and the volume of the solid from that of the pyramid having one of the faces for its base, and the radius of the inscribed sphere for its altitude.

Besides the five regular polyhedrons of Plato, there are the *semi-regular* ones of Archimedes, for an account of which see POLYHEDRON.

Regulars. In the Roman Catholic Church, those who profess and follow a certain rule of life, and observe the three vows of poverty, chastity, and obedience. Hence monks in holy orders constituted the body of the regular clergy, as distinguished from the seculars, or clergy who were not under vows.

Regulator. In Machinery, a general name for any contrivance of which the object is to produce the uniform movement of machines. The regulators most commonly applied are the FLY and the GOVERNOR, for which see the respective terms.

The regulator of a watch is the spiral spring attached to the balance. This ingenious contrivance, the invention of Hooke, has contributed as much to the improvement of watches as the pendulum to the improvement of clocks.

In a paper published in the *Memoirs of the Royal Astronomical Society*, vol. xi., the present Astronomer Royal has investigated the mathematical problem of the motion of the regulator applied to the clock-work by which motion is given to large equatorial telescopes. For this purpose absolute uniformity of motion is of very great importance. The construction usually adopted, in this country at least, depends on the same principle as that of the governor of the steam engine. Two balls suspended from the upper part of a vertical axis by rods of a certain length, are made to expand by the rotatory velocity of the axis; and when the expansion reaches a certain limit, a lever is pressed against some revolving part, a friction being thus produced which immediately checks the velocity. Now the uniformity of the rotatory motion of the spindle depends upon the assumption, that if upon the whole the retarding forces are equal to the accelerating forces, the balls will move in a circle, and in no other curve. But this assumption is incorrect; for the balls may move in a curve differing insensibly from a circle; and, in some instances, Mr. Airy observed the balls to revolve in an ellipse of considerable eccentricity. When this takes place, the rotatory motion of the spindle becomes exceedingly variable. This injurious effect may be partly counteracted by constructing the apparatus so that the revolutions shall be either very slow or very quick: the former method has the effect of giving greater smoothness of motion, but the second insures more completely that the object observed shall remain steady in the field of the telescope.

Regulus (Lat.). In Chemistry. The old chemists designated by this term several of the brittle or inferior metals when freed from impurities and obtained in their metallic state. Thus they speak of *regulus of antimony*, *of bismuth*, &c. The term is now often used by metallurgists to denote the metallic button which is found at the bottom of an assay crucible.

There is still, however, considerable confusion in the use of this term; thus German assayers use it in the sense just given, whereas in England it usually signifies a mass of sulphides, and especially of copper, such as is got in the concentration of poor copper ores by fusion.

Regur. The name given to the cotton soil of India, which extends over at least one third part of Southern India, and ranges northwards to some distance. It chiefly characterises the high plateaux of the Deccan, covering the nearly level plains of that district. Its colour is bluish-black, greenish, or dark grey. It forms a paste with water, and has a clayey odour when breathd on. It absorbs moisture rapidly, and dries into a powder in hot weather. Its thickness varies from three to twenty feet, and it may be cultivated year after year without manure, almost without husbandry, and with very rare fallows. It consists of about 50 per cent. silica, 20 per cent. alumina, and 25 per cent. of the carbonates of lime and magnesia. The quantity of organic matter is small.

Rehabilitation (a word coined from Lat. re, and habilis, *active*, in the sense of restoration to vigour). In Foreign Criminal Law, the reinstatement of a criminal in his personal rights, which he has lost by a judicial sentence. Thus, in Scotland, a pardon from the king is said to rehabilitate a witness labouring under *infamia juris*. In France, persons condemned to imprisonment or compulsory labour may demand their rehabilitation five years after the expiration of their penalty.

Rehearsal. The recital in private of any dramatic work, previously to public exhibition.

Reichsrath (Ger. *council of the empire*). Under the old constitutions of the German empire, the reichshofrath was a council of state, charged with important judicial functions. [Aulic Council.] In the Austrian empire, the reichsrath answered to the senate in France, and aided the sovereign in the administration of the empire. But by imperial patent of March 1860, the emperor reconstituted this body by adding to the original or *narrow* reichsrath (consisting of eighty members) other representative members to be elected by the provincial assemblies: to take into consideration, (1) the annual budget; (2) the more important bills for enactment into general laws; (3) the proposals of the provincial constitutions. The species of constitution thus established has been very recently subjected to innovations, intended to take from the power of the reichsrath and add to that of the several legislatures of the provinces comprising the empire.

Reichstadt (Ger. *city of the empire*). The designation given to the several free cities which under the old German constitution held immediately of the empire. Of these Hamburg, Frankfort, Bremen, and Lubeck now alone retain their independence. [Hansa.]

Reichstag. [Diet.]

Reindeer (Ger. rennthier). *Cervus tarandus*, Linn. A large species of *Cervus* with branched, recurved, sub-compressed antlers, the summits of which are palmated. These antlers are remarkable for the size of the branch which comes off near the base, and is directed forwards, called the *brow-antler*, and which is said to be used by the animal to clear away the snow from the hidden lichens which constitute its food during the long and severe winter of Greenland, its native clime. As the female also possesses antlers of similar form, but smaller upon the whole than those of the male, their function as instruments to obtain food is rendered more probable, since in the deer which do not exist in arctic climes the females are destitute of antlers. These appendages of the

reindeer are annually shed and renewed in both sexes.

The length of a full-grown male is about nine feet, that of the head is fifteen inches. They are well clothed with hair, which becomes thicker, longer, and of a whiter colour in the winter season; at which time the male has a white beard like the goat. The rutting season is at the beginning of winter, and the hind brings forth one, rarely two, calves in May or June.

The reindeer is swift of foot, sharp-sighted, and has an acute smell and hearing. It is more cautious and timid in herds than when solitary. It can swim well, and often crosses lakes and rivers.

The flesh of the reindeer, which is held in great esteem by the Greenlanders, is usually eaten raw, or dried with the smoke of the *lichen nivalis*. The blood is boiled with berries mixed with the fat, which is also preserved separately and used as lard. The half-digested contents of the paunch of the reindeer form the Greenlander's prime luxury; nor is the tail rejected. The hide of the reindeer supplies the Greenlander with a beautiful material for his tent, his clothing, and his bedding. The bones and antlers are worked into implements for domestic use, for fishing and hunting. The tendons are split into threads. The Greenlanders likewise use the spare hides of the reindeer as an article of barter.

Reinecke the Fox. The name of a celebrated popular German epic poem, which, during the latter part of the middle ages and the early centuries of modern times, enjoyed an almost European reputation, having first become known through the medium of a Low German version in the fifteenth century. It contains a humorous and satirical account of the adventures of Reinecke (the fox) at the court of King Nodel (the lion); exhibits the cunning of the former, and the means which he adopted to rebut the charges preferred against him, and the hypocrisy and lies by which he contrived to gain the favour of his sovereign, who loaded him with honours. The king, the officers of his court, and all his subjects are represented, as in *Æsop's Fables*, under the names of the animals best suited to their respective characters; and the poem is an admirable satire on the intrigues practised at a weak court. The most successful versions of this poem are those of Goethe, in hexameters; of Soltau, in the measure of the original; and the more recent attempt of Ortlepp.

This poem appears, in some form or other, to have been known throughout Europe. For full information respecting it, the reader may consult Meon, *Roman du Renard*, Paris 1826; and the *Reinhart Fuchs*, by Jacob Grimm, Berlin 1834.

Reinforce. In Artillery. This word was used originally to signify an additional thickness of metal, given to *reinforce* or strengthen the gun about the breech. Though still employed in the same sense in America, it has now in England almost lost this meaning, and is generally understood to signify the part of the gun thus *reinforced*.

A smooth-bored cast-iron or bronze gun is divided for purposes of nomenclature into parts. That portion of the gun between the base ring and the ring nearest to the trunnions is divided into two parts, called respectively *first* and *second reinforce*. [Gun.] Rings round the gun where these parts end are called *reinforce rings*.

Reis, Rais, or **Ras** (Arab. *head*, *prince* or *chief*). A title popularly used for various persons in authority in different parts of the wide regions over which the Arabic language more or less prevails: e.g. the captain of a ship. In Bengal, managers or occupants of religious endowments are sometimes so termed.

Reis Effendi. The name given to one of the chief Turkish officers of state. He is chancellor of the empire and minister of foreign affairs, in which capacity he negotiates with the ambassadors and interpreters of foreign nations.

Reiters. The German cavalry of the fourteenth and fifteenth centuries were so called; especially in France during the religious wars, in which they served on the Protestant side. At that period they were light-armed, and carried a long sword and carbine.

Rejoinder. In Law, the fourth stage in the pleadings in an action, being the defendant's answer to the plaintiff's replication. [Pleading.]

Relapsed (Lat. relapsus, part. of relabor, *I fall back*). A term applied, in Ecclesiastical Law, to a heretic who falls back into an error which he has abjured.

Relation, Inharmonic or False. In Music, a term denoting that a sound is introduced which has a dissonant or false relation with some sound in the preceding chord.

Relative Magnitude. [Ratio.]

Relative Motion. [Motion.]

Relative Pronoun. In Grammar, a part of speech which, while it may represent any noun or prepositive pronoun, possesses also a connective force which makes the clause introduced by it practically an adjective. Thus the words, 'A man who speaks much is not likely to be wise,' may be resolved into the expression 'A man of many words is not likely to be wise.'

Relative Terms. In Logic, words which imply a relation, as father and son, master and servant.

Relator (Lat.). When a suit in chancery is instituted in a public matter not directly touching the rights of the crown, e.g. for the regulation of a charity, the course is for the attorney-general to file an *information* on the *relative* of some person. This person is called the *relator*, and is responsible for the costs of the suit, in which he is in fact usually the real plaintiff. A similar name is given to the person at whose instance an information in the nature of a *quo warranto* is filed.

Relbun. The roots of *Calceolaria arachnoidea*, which are used in Chili for dyeing woollen cloths crimson.

Release (Lat. relaxare, *to loosen*). In Law, this word signifies, properly speaking, a discharge of a right; e.g. 1. A release of land is a discharge or conveyance of a man's right in lands and tenements to another that has some former estate in possession, on which principle the mode of conveyance by lease and release in use formerly (before land could be legally conveyed by a simple deed of grant) was founded; i. e. releasing all the right of the releasor to a party already in possession under a lease for a year. 2. A release of a right of action or suit, or of some right, claim, demand, &c. It is usual to express these releases in very general terms, but the Court of Chancery will nevertheless interfere to prevent their being used as a defence against any claims or demands but those of which the parties were aware, and from which in fact they designed to be released.

Relics (Lat. reliquæ). In the Roman and the Eastern communions, the remains of saints, or of their garments, &c., which are enjoined to be held in veneration and are considered in many instances to be endued with miraculous powers. They are preserved in the churches, to which they are often the means of attracting pilgrims.

Relief (Ital. rilievo). In Architecture, the projection of a figure or ornament from the ground or plane on which it is sculptured.

Relief. In Feudal Law, this term is derived from the Latin relevare, *to take up*; because the tenant, by payment of the relief, was said to take up the fief which had fallen to the lord by the death, &c. of his predecessor. 'The heir,' says Blackstone, 'when admitted to the feud which his ancestor possessed, used generally to pay a fine or acknowledgement to the lord in horses, arms, money, or the like, for such renewal of the feud; which was called a relief, because it raised up and re-established the inheritance, or, in the words of the feudal writers, "incertam et caducam hæreditatem relevabat."' Reliefs, together with the other incidents of feudal tenure, were abolished in England by stat. 12 Ch. II. [Feudal System.]

Relief. In Fortification, the relief of any point in a work is its vertical distance from a horizontal plane coincident with the base of its scarp. The relief of a work implies the relief of the crest of the parapet, i. e. its height above the base of its scarp.

Relief. In Military language, the party detached from a guard to relieve the old sentries at the expiration of their term on duty.

Relief. In Sculpture, when the whole of the figure stands out, the work is denominated *alto-rilievo*; when only half out, *mezzo* or *demi-rilievo*; and when its projection is very small, it is called *basso-rilievo*.

Relief Synod. A body of Presbyterian dissenters in Scotland, whose ground of separation from the established church was the violent exercise of lay-patronage which obtained in the latter. Though patronage, or the appointment of clergymen to church benefices by presentations, had been established by Act of Parliament in 1712, yet a minority of the clergy were opposed to the intrusion of a minister into a parochial charge contrary to the sentiments of the people. The majority of the church, however, rigorously enforced the provisions of the Act of 1712. With this state of things the people generally, but particularly in rural districts, were dissatisfied; and hence the origin of the Secession church, and the Relief. [Burghers.]

The origin of the Relief may be dated in 1752. Six of the ministers of the Presbytery of Dunfermline having refused to assist at the admission of Mr. Richardson to the parish of Inverkeithing (the people being unwilling to receive him as their pastor), were summoned before this court for contumacy; and, as an example to the church, one of the six recusants was peremptorily deposed from the office of the ministry, while the remaining five were suspended. Mr. Gillespie, minister of Carnock, the person deposed, still claimed his pastoral relation to his flock; and though deprived of the use of the parish church, preached in the fields, attended not merely by his former hearers, but by many others attracted by the circumstances of the case. Gillespie for a few years stood alone; but in consequence of the violent settlement of a clergyman in the town of Jedburgh, the great body of the people of that place, forsaking the established church, gave a call (1759) to Thomas Boston, minister of a neighbouring parish, who accepted the invitation, and withdrew from the church of Scotland. The people of the parish of Kilconquhar, in Fifeshire, followed the example set them in Jedburgh, and chose Mr. Collier to be their minister. On the 22nd of November, 1759, Gillespie and Boston, with a lay elder from each of their congregations, met in a presbyterian capacity at Colinsburgh, in the last-mentioned parish, to induct Collier to his charge. On the evening of the same day these three ministers met, and agreed to form themselves into an ecclesiastical body, to be called the 'Presbytery of Relief, for the relief of Christians oppressed in their Christian privileges.' This sect gradually formed itself into a synod, which, in 1851, embraced eleven presbyteries, including 116 congregations; being, in point of numbers and influence, the third ecclesiastical body in Scotland. (Smith's *Historical Sketches of the Relief Church*; Hutchison's *Compendious View of the Synod of Relief*; Adam's *Religious World Displayed*, vol. iii. pp. 223–32; M'Kerrow's *History of Secession*, vol. i. pp. 319–24, 326–28.)

Relieving Tackles. Temporary tackles attached to the end of the tiller in bad weather to assist the helmsman, and in case of accident happening to the tiller ropes or wheel. The term is also applied to strong tackles from the wharf or other object, to which the ship is hove down or careened, passed under her bottom and attached to the opposite side, to assist in righting her afterwards, as well as to prevent her from oversetting entirely.

Reliquary. A receptacle for relics. The difference between a *reliquary* and a *case* (Fr. châsse) used for the same purpose is, that the former is smaller in dimensions, and contains only small fragments; the latter in many instances entire bodies.

Remainder. In Arithmetic and Algebra, the difference of two quantities, or that which is left after subtracting one from the other.

REMAINDER. In Law, a remainder is defined by Lord Coke to be 'a remnant of an estate in lands or tenements expectant on a particular estate created together with the same at one time.' It is clear that if an owner of land in fee simple conveys it to some person for an estate less than his own (as for instance for an estate for life) there will be a *remnant* of the original estate in fee simple undisposed of. If the original owner retains this *remnant* himself, it is called his *reversion*; but if he conveys it to anyone else, it is termed a *remainder*; thus if land is granted to A for his life, and after his death to B and his heirs, B is said to have a vested remainder in fee simple expectant on the death of A. The limitation of the remainder confers on B a present absolute right to the future enjoyment of the property, whenever the life estate of A (called the *particular estate*) determines; in other words, B has a *vested* estate in remainder. A vested remainder is a remainder which is conveyed or limited unconditionally, and if a remainder is not vested it is *contingent*. But a remainder may be originally a contingent remainder, and afterwards become a vested remainder; thus in the case of land being settled on A (a bachelor) for his life, and after his death on his eldest son in fee, the remainder to the son is contingent so long as A has no son; but as soon as A marries and has a son, the remainder vests in the son, and will take effect in favour of him or his representative whenever A dies. But if a contingent remainder is so limited as not to vest during the continuance of the preceding (or particular) estate (which must be in such case an estate of freehold), or as soon as it determines, it will fail altogether; thus if land is settled upon A for life, with remainder to such of his children as attain twenty-one, and he dies leaving only infant children, the remainder to the children will wholly fail, although in the case of personal property, or even in the case of land vested in trustees, such of the children as eventually attained twenty-one would take, although they might have been minors at the death of their father. The failure of the remainder in the case above suggested is a consequence of the rule that the seisin or feudal possession of land must never be without an owner, a doctrine which forms one of the first principles of English real property law, but which is now a mere technicality, fatal to many unskilful dispositions of property, but easily evaded by the expedient of vesting the land in trustees.

The creation of contingent remainders is restrained within due bounds by another rule; viz. that an estate cannot be given to an unborn person for life, followed by any estate to the child of such unborn person; for in such case the estate given to the child of the unborn person would be void; as, for instance, in the case of a limitation to A (a bachelor) for life, with remainder to his eldest son for life, with remainder to the eldest son of such eldest son in fee, the latter limitation will be simply void. [PERPETUITY.] (*Penny Cyclopædia*, art. 'Remainder;' Williams *On Real Property*.)

Remand (Lat. re, and mandare, *to commit*). In Law, the recommittal by a justice of a person charged with a serious offence to prison for a limited time, when it is necessary to postpone the preliminary examination on account of absence of witnesses or other serious cause: regulated, in England, by the Act 11 & 12 Vict. c. 43.

Remanet (Lat. *it remains*). In Law, a cause the trial of which is postponed from one sitting to another.

Remblai (Fr.). A term of Engineering, used by the French authors to express the earthwork that is carried to bank, in the case of a railway, or canal traversing a natural depression of the surface.

REMBLAI. In Fortification, the earth or materials used to form the whole mass of rampart and parapet. It may contain more than the *déblai* from the ditch. [DÉBLAI.]

Remedy (Lat. remedium). A term used at the Mint in reference to a certain *allowance* in the weight and quality or fineness of the coin of the realm. It occurs in an indenture granted by Edward VI. (A.D. 1435) to Robert Mansfield (*maître et ouvrier des monnoys d'or et d'argent en la tour de Londres et en la ville de Caleys*). It occurs again in an indenture granted in 1465 to William Lord Hastings, and is explained as follows: 'And because the said monies of gold may not continually be made according to all things to the right standard, but peradventure in default of the master and worker it shall be found sometimes too strong or too feeble in weight or in alloy, or in both, our sovereign lord the king willeth that when the said money be found at the assay before the deliverance thereof too strong or too feeble all only in weight or all only in assay or in either by the 8th part of a carat in the pennyweight of gold, which 8th part shall be called *remedy*, the money shall be delivered for good when the said default shall happen *casually*, otherwise not. If the remedy is exceeded, then the deliverance of the money is to be *challenged*, and new molten and reforged at the expense of the master.'

At present the working remedy allowed upon the pound troy of standard gold, is 12 grains as to weight and 15 grains as to fineness. Twenty troy pounds of standard gold are coined into 1,869 sovereigns, or each troy pound into $46\frac{29}{40}$ sovereigns.

Remembrancers. Officers of the Court of Exchequer, and of some corporations who

perform various functions, are so called. The office of queen's remembrancer has been regulated by various modern statutes (5 & 6 Vict. c. 86, 22 & 23 Vict. c. 21, &c.).

Remiges (Lat. *rowers*). The quill feathers of the wings of a bird, which, like oars, propel it through the air.

Remijia (after Remijo, a Brazilian physician, by whom the bark was first used). A genus of *Cinchonaceæ*, consisting of Brazilian shrubs, some species of which are called Quinas, their bark being used as a substitute for *Cinchona*. *R. ferruginea* and *R. Hilarii* are called Quina de Remijo; and *R. ferruginea* and *R. Vellozii*, Quina de Serra.

Remingtonite. A hydrated carbonate of cobalt, occurring as a thin opaque rose-coloured coating upon Serpentine, at the copper mine near Finksburg, in Maryland; and named after the superintendent of the mines.

Reminiscence (Lat. reminiscor, *I remember*). In the theory of Plato, knowledge was only a reminiscence (ἀνάμνησις) or recovery of truth which the soul had possessed in a former state of existence, but which it had forgotten since it began its sojourn on earth.

Remipeds (Lat. remus, *an oar*, and pes, *a foot*). The name of an order of Coleopterous insects, including those which have tarsi adapted for swimming.

Remission (Lat. remissio, *a slackening*). In Pathology, the abatement of a disorder, or regular mitigation of symptoms, as opposed to *intermission*, in which the symptoms of disease for a time entirely disappear. [REMITTENT FEVER.]

Remittent Fever. Any fever which suffers a decided remission in its violence during the twenty-four hours, but without entirely leaving the patient, is called a *remittent*; it differs from an intermittent because in the remittent there is never a total absence of fever. These fevers are most common in autumn, and they vary in degree from extreme mildness to alarming violence. The remittent fever of children, or, as it is often called, *infantile fever*, is now generally allowed to be typhoid fever: the tongue is very foul, the head aches, the belly is tumid, food is loathed: the child is drowsy all day, but restless and often delirious at night, and the bowels are generally very irritable. Good air, thorough ventilation, light farinaceous diet, and carefully exhibited support and stimulus usually effect cure, though the bowel affection sometimes requires the use of starch injections combined with syrup of poppies or tincture of opium. The *yellow fever*, or bilious remittent of hot climates, and especially of the West Indies, is another form of this fever: it appears to be produced by marsh miasma. In all these fevers particular symptoms occasionally present themselves, which require special modes of treatment; and this must also be modified according to the inflammatory, malignant, nervous, or intermittent form which they may assume or pass into.

Remitter. In Law, a remitter exists where he who has the right of entry in land, but is out of possession, obtains afterwards the possession of the land by some subsequent or defective title: in which case he is *remitted* or sent back, by operation of law, to his own preferable title; as, for instance, if A wrongfully evicts B, and then lets him the land (without deed) on a yearly tenancy, B on entering will be remitted to his prior and better title, though this result would not follow if he had accepted a formal lease by deed.

Remolinite. Atacamite from Los Remolinos in Chili.

Remonstrance, The. In English History, the name given to a document presented by parliament to Charles I. in November 1641. It recapitulated all the grievances which had existed since his accession. (Hallam, *Constitutional History of England*, ch. ix.)

Remonstrants. In Ecclesiastical History. [ARMINIANS.]

Remora. A genus of fishes (*Echineis*) in which the dorsal fin is so modified as to become a flattened disc covering the top of the head, composed of movable cartilaginous plates directed obliquely backwards. The fish attaches itself to a foreign body by this structure; and from this well-ascertained fact many fables have been invented regarding the genus; amongst others, one which asserts that the fish possesses the power of arresting the course of any ship to which it may have attached itself.

Remoteness (Lat. remotus, *moved back*). In Law, dispositions of property which are invalid by reason of their contravening the rule against perpetuities [PERPETUITY], are often said to be void for remoteness.

Remphan. This deity is said to have been worshipped by the Israelites while in the wilderness. The passage in Acts vii., which speaks of them taking up the tabernacle of Moloch and the star of their god Remphan, is supposed to refer to the words of Amos, 'Ye have borne the tabernacle of your Moloch and Chiun, your images.' Chiun and Remphan would on this hypothesis be the same, and both are thought to denote Sirius, the dog-star.

Renaissance (Fr.). In Architecture, a term applied to the style which sought to reproduce the forms of Greek ornamentation. This style, of which the idea had never died out in Italy, marks especially the age of the revival of letters, which immediately preceded the Reformation. It has, however, no necessary connection with the tone of religious thought which characterises the various Protestant bodies in Europe. It had taken root in Italy before Martin Luther raised his standard against the papal power; it has been retained there, although the people of Northern Europe have shown a disposition to abandon it.

The term *Renaissance* has been very vaguely applied to denote a number of styles which have but little in common. There is no doubt that in the general principle of truthfulness the first phase of Renaissance in Italy agreed closely with the Gothic styles which it sought to

supplant. In both, the ornamentation either grew naturally out of the construction, or was such as was best suited to express the uses or objects to which the building was to be devoted. We are thus supplied with a test which Mr. Fergusson, in his *History of the Modern Styles of Architecture*, has used to distinguish the one true form of Renaissance from the many spurious styles which have succeeded it. Ornamental forms, though avowedly borrowed, may be rightly applied. The Greek shaft and capital, used as a support, is as much in its right place as a Gothic pier: attached to a wall, where it supports nothing, it is put to a use for which it is not adapted, and which is therefore wrong. Hence, as soon as pieces of entablature were thrust in where they were not wanted, or columns became mere ornamental appendages, the style ceased to have a legitimate existence. This strict application of the term cuts down the true Renaissance to a very short life indeed; for the era opened with the sojourn of Brunelleschi at Rome during the early part of the fifteenth century. He returned to Florence in 1420, and died in 1444; in the interval he had erected buildings in which pieces of entablature were thrust in between the pier and arch, and so left to his successors 'the most fatal gift of classic art to modern times.' If these limits are accepted, the Renaissance, like the geometrical Gothic style, has little more than a philosophical existence.

In truth, the Renaissance architects followed the example of the older Roman builders, who disguised their genuine arched construction under forms borrowed from Greek art, or cast away that construction altogether. [ARCHITECTURE, ROMAN.] The architecture so cast aside contained the germ of the Teutonic or Gothic styles; and its abandonment by the Romans only served to check for centuries all real progress in art. But in the fifteenth century the Gothic architecture had worked itself out, and the most debased forms had been adopted long before John of Padua designed Longleat, or Inigo Jones drew out his plans for Whitehall. Hence there is nothing surprising in the fact that the countries in which the Reformation took root most firmly, were the last to take up the actual forms of Renaissance architecture. Yet the Reformation, although it cannot be regarded as the cause of the introduction of Renaissance forms into the architecture of Northern Europe, undoubtedly checked the passion for church building, which in Italy remained as strong as ever. But in Italy the Gothic forms had never been really congenial. The so-called Gothic churches of Assisi, Vercelli, and Milan had been built by northern architects. But the Renaissance architects, while casting off Gothic trammels, bestowed little thought on maintaining that truthfulness of ornamentation without which no style can have any real life. The Romanesque and Gothic styles had come into existence by casting aside the entablature from all disengaged columns (Okely, *Christian Architecture in Italy*, p. 3): the Italians of the fifteenth century felt an irresistible temptation to return to it. The former acquired strength by reverting to the genuine forms of ancient Roman construction: the latter once more placed on their necks the yoke which had crushed the native powers of the older Italian architects in the days of Cicero and Mæcenas.

The result of this adoption of an unnecessary member as a prominent form in ornamentation was a spirit of slavish copying; and in the absence of a living style applicable to all buildings, the history of modern architecture resolves itself practically into a series of biographies of modern architects. We are concerned not with the developement of principles, but with the designs of particular men; and to form a judgment of these we can make use only of certain canons of taste, in which it seems impossible to insure anything like a general agreement. We cannot decide conclusively whether the temple of Theseus is more beautiful than the choir of Cologne; but we can decide without fear of contradiction whether each of them is or is not inconsistent with the laws of construction and decoration which regulate their respective styles.

The strictly imitative character of the Renaissance is still more clearly brought out by the fact that many of the greatest buildings in this style are classical only in their details, their forms being borrowed from early Christian basilicas or Gothic and Byzantine buildings. To these forms it applied a principle of decoration which could issue only in a wearisome sameness. The Greek column was a strictly constructive feature; in Roman hands it became an appendage of a wall where it supported nothing. The Renaissance architects went a step further by employing pilasters instead of columns, and thus introduced 'one of the most useless as well as least constructive modes of ornamentation that could be adopted.' Having employed these pilasters on useless porticoes, they went on to employ them on the walls of houses, where they give no support whatever. This, in Mr. Fergusson's opinion, was a further step 'in the wrong direction; it was employing ornament for ornament's sake, without reference to construction or the actual purpose of the building; and once it was admitted that any class of ornament could be employed other than ornamental construction, or which had any other aim than to express, while it beautified, the prosaic exigencies of the design, there was an end of all that was truthful or that can lead to perfection in architectural art.' The columns thus came at length simply to indicate internal arrangement, and were separated into distinct layers by large entablatures which preclude all real unity of design. Hence resulted that exaggeration of the orders, which, as Mr. Fergusson maintains, marks the worst stage of Renaissance architecture. There is no reason why in many of the Venetian or Florentine palaces the stages should not be more in number or less; they might be multiplied without affecting the general character of the design.

The tendency to imitative forms is shown in the best specimens of the style—in the church of Lodi as in the Grimani and Guadagni palaces. On the other hand, there are some buildings which with so-called classical forms exhibit nothing of the spirit of classical art. In the church of the Annunciata at Genoa, no fragment of entablature is thrust between the Corinthian capital and the arch; while vertical lines, running up from the capital, make the space between the string-course and the cornice practically a triforium.

The general conclusion to be drawn from these facts seems to be that the Renaissance architecture is not, strictly speaking, a distinctive style, but simply a method of ornamenting forms which may be Greek, Roman, or Gothic in their character.

The practical questions involved in the subject are discussed at length by Mr. Fergusson in his *History of Modern Architecture*; while an examination of his opinions may be found in an article in the *Edinburgh Review* (for July 1864, p. 71), in which the principles of Renaissance art, here briefly sketched, are illustrated in greater detail.

Renal Glands (Lat. renes, Gr. φρήν, φρένες, *the midriff*). There is a glandular body upon each kidney, of a somewhat triangular shape, small in the adult, but of larger relative size in the fœtus; it is called the renal, or supra-renal, gland or capsule: it has no excretory duct, and its use is unknown. These ductless glands are remarkable for their rich supply of nerves from the solar plexus: in comparative anatomy they are known as the *adrenals*.

Rendered. In Architecture. [RENDERED AND SET.]

Rendered and Floated. In Architecture, plastering of three coats on brickwork.

Rendered, Floated, and Set for Paper. In Architecture, a term used to express plastering of three coats: the first being lime and hair upon brickwork; the second, the same compound, with the addition of a little more hair, which is brought to a level surface by being *floated* with a long rule; the third, fine stuff mixed with white hair, laid on with a trowel.

Rendered and Set. In Architecture, a term used to denote the plastering executed in two coats, on naked brickwork or on stonework. If the work is to be of three coats, the first of these is called the *pricking-up* coat, which is afterwards rendered and set; this is sometimes calling *roughing in*. The materials for the pricking-up coat and the rendering coat are identical; the setting coat is, generally speaking, of a finer kind of lime.

Rendezvous (Fr.). The Military term for the place appointed for the assembly of a body of troops.

Rennel's Current. An important though not very extensive current, commencing near Cape Finisterre, and running along the northern coast of Spain and the west coast of France, and so entering and crossing the English and Irish Channels to Cape Clear, whence it enters the Atlantic and is deflected again towards the south and south-east. It sets generally at the rate of about one mile an hour, and connects itself with a parallel current which flows to the north-west coast of Africa, and is therefore in the opposite direction. This latter return current proceeds along the African coast, and connects with the EQUATORIAL CURRENT. Both, no doubt, have much influence on the climate of Western Europe, but being inconsiderable in force they are liable to be much affected by modifications of the Gulf Stream.

Rennet or **Runnet** (Ger. rinnen, *to curdle*). The prepared inner membrane of the calf's stomach, which, in consequence of the presence of pepsine, has the property of coagulating the casein of milk and separating it from the whey in the form of curd.

Rensselaerite. A steatitic mineral named after Van Rensselaer. It occurs over large areas, in Northern New York and in Grenville in Upper Canada; and is, probably, identical with Pyrallolite.

Rent (Ital. rendita). In Political Economy, that portion of the produce of the soil which the competition for produce enables the owner of the soil to appropriate. Strictly speaking, rent is paid for the natural capacity or fertility of the soil only, though in popular language it is used to denote such sums as are paid for the use of capital permanently fixed in the soil, as, for instance, the draining of an estate, and the buildings which have been erected on land. Payments, however, for these conveniences or utilities are not rent, but interest or profit on capital. But whatever it be that constitutes economical fertility, whether it be the capacity of certain soils for particular crops, or the excellence of certain sites for building houses to be used either for business or pleasure, provided the capacity or excellence is due to natural causes only, the annual compensation paid for the use of these inherent advantages or conveniences is rent.

The first condition of rent is that there should be competition for the object in question. If natural fertility be unlimited in quantity, no rent can be obtained, for no one will give anything for that which he can procure at pleasure. But if the soil be appropriated, even though it may not all be tilled, rent will arise by the fact that the person or persons appropriating it have created an artificial scarcity, and so a market for natural fertility. The unenclosed and fertile lands of Australia are practically unlimited, and will be so, even with the most rapid increase of population conceivable, for centuries to come. But as the local governments, partly to prevent too great a dispersion of population, partly to create an emigration fund, have assumed the ownership of all land in the various colonies, and grant it only on payment and certain other conditions, a rent is possible, even on plots which have not had a shilling of capital permanently

expended on them. So in the middle ages and under the feudal system, all land had an owner, and therefore was made liable to rent. The rent, it is true, was low, and was extorted from the cultivator; but its origin is to be found in the appropriation of the soil, and in the necessities of the general population, who were constrained to submit to the terms imposed upon them.

Next, the produce of the soil must, by the effect of competition, be valued at a price higher than that which suffices to remunerate the cultivator for the wages of his labour and the profit of his capital. If wages be left to competition, and no attempts be made to depress them by direct legislation, the possibility of rent is postponed till such time as the demands of population raise the price of produce and lower the rate of wages. However cheap may be the cost of production, and however abundant the amount produced, no rent will be obtained till such time as the price paid for produce is greater than satisfies wages and profits. And that which applies to agriculture applies also to trade. The competition for favourable sites to be employed for trading purposes creates a rent, partly because the available area is by the very terms of a competition limited, partly because the amount of advantage in business favourable for the occupation of such sites is so much greater than could be obtained in other sites, that the owner of the soil is enabled to share in the gross profit of the business carried on in the favourite locality. The fertility of a business site is accidental, no doubt, but it is an accident which affects the land, not the business; and hence, however originated, it is of the same nature with the natural fertility of land capable of cultivation.

The modern theory of rent adopted by political economists is said to have been suggested by Anderson in 1737, but the credit of the discovery is generally shared by Mr. Malthus and Sir Edward West, the theory having been elaborated by Mr. Ricardo. It is to the effect that in newly settled countries, where abundant fertile land can be voluntarily occupied, no rent is possible; but that when, owing to the pressure of population and the demand for produce, a price can be obtained for food in excess of that which remunerates the cultivator of the best or most fertile soils, i.e. such soils as produce the largest amount of food with the least expenditure of labour, inferior soils must needs be occupied, i.e. soils on which either a less amount is produced by equal labour, or an equal amount by greater labour; and that under the circumstances, since a manifest advantage belongs to the best soils, the advantage will either, in case the ownership of the land remains with the cultivator, be covertly rent, or, in case the land belongs to one man, and the capital by which it is cultivated is supplied by another, it will appear as rent paid to the former person. In either case it will be, though entirely separate from any capital expended on the soil, available as an object of sale or mortgage.

To supply an instance in which the minimum amount of fixed capital resident in permanent improvements may be eliminated, let us suppose that there is natural water meadow on the banks of the Thames, the annual fertilisation of which is fully supplied by the natural warping of the river at the seasons of its overflow, and that consequently the only labour employed on the crop of hay consists in mowing, drying, and stacking the produce; and that the ordinary rate of produce is three tons to the acre, worth on an average 4*l.* the ton on the spot. Let us conceive also that the cost of labour, the wages of haymakers, the maintenance of horses and carts, and some other small matters, with the profit on the farmer's capital, and the remuneration which he obtains for his own superintendence and risk, amounts to 6*l.* an acre annually. Let us, on the other hand, conceive that the produce of hay on an upland pasture, which needs to be manured, dressed, and occasionally cropped, is two tons an acre, and is saleable at the same average rate, and that the aggregate charges of the labour &c. expended on the latter amount to 7*l.* 10*s.* the year per acre. The rent of the first parcel will be 6*l.* an acre, and of the latter 10*s.* If the amount of produce procured in the latter case is worth on an average no more than the charges expended on cultivating the land, no rent at all will arise, although perhaps in the total amount of land rented by a farmer a rent may seem to be paid, because the total rent is estimated by the total acreage. And the fact that all land yields a rent is not inconsistent with this view, for the rent of some parcels of land employed, for instance, as sheep-walks, is paid only because other parcels of land which must needs be let along with such sheep-walk, in order to provide winter fodder, are let at a lower rent than they would be if they were let alone, and the sheep-walk were devoted to different purposes. If we vary the instance, and take the produce of corn instead of that of hay, the result would be the same, though the conditions would be more complex.

In brief, therefore, the Ricardian theory of rent, as ordinarily understood, implies that rent has arisen from the necessity which exists for the cultivation of inferior soils, this necessity having itself been caused by the growth of population, and its demand for agricultural produce. Further, it is held that this necessity for cultivating inferior soils increases with the increase of population, and that there is no limit to the necessity put upon agricultural labour, and consequently upon rent, until the labour required to extract food from the least productive soils is to be valued at as much as the produce obtained from them.

This theory, however, appears by no means to account for all the causes which increase and diminish amounts of rent; nor will the application of the theory to certain social conditions be found either to agree with or at

least to explain many unquestionable economical phenomena. It accounts for differences in rent; and taking the facts of the great variety in the natural powers of the soil, it supplies from these data some information as to the origin of rent, and the limit at which rent is no longer obtainable. But suppose that the whole soil of a country were equally fertile, i.e. that it produced equal quantities by equal labour, and that no increase of produce were possible except by greater labour, or (what comes to the same thing) greater skill, the application of new forces, and the substitution of mechanical instead of manual labour. Would there be no rent in such a case? There certainly would be as soon as ever the demand for the produce exceeded the cost of production, i.e. immediately, for the excess of demand is, and has been, concurrently with other causes, the motive for diminishing the cost of production.

Rent appears to be the function of two variables: the cost of production, and the demand for the produce. When no demand arises in excess of supply, there is not, as in other occupations, any disposition to diminish the cost of production. When population is either stationary, or when, if it be progressive, the supply of fertile land is unbounded, the progress of agricultural science is very slow, all economy tending in the direction of the substitution of mechanical for manual labour in the latter case, and no stimulus to economy being provided in the former. It is a well-known fact that no more powerful motive to agricultural improvement has been found than in an increase of rent, and that when rents are, either by the indulgence or negligence of landlords, much lower than the possible amount procurable, land is ill or imperfectly cultivated. And the reason is obvious. Rates of profit are, equal conditions being fulfilled, equal in different occupations. But rent is whatever is produced in excess of the rate of profit. Now, as the farmer knows, or acts unconsciously on the fact, that rent is derived from this excess, he has no natural impulse to procure, except under the pressure of demand, more than the general rate of profit which will satisfy him for his capital and superintendence. But the common theory of rent always takes for granted that a diminished cost of production has a tendency to lower rents. Such an inference, however, is contrary to facts, and repugnant to the economical axiom that the rates of profit tend to an equality. The rent of arable land in the fourteenth century was *6d.* an acre on an average. The price of wheat was about *5s. 4d.* In modern weights of coin the former was *1s. 6d.* an acre, the latter was *16s.* the quarter. But the average price of wheat has risen in weight of silver about 3½ times, i.e. to about *56s.* the quarter, while the same land now lets at *30s.* to *2l.* the acre, i.e. at from ten to thirteen or fourteen times the previous rate. Yet it is absurd to say that the demand for food is greater now than it was in the fourteenth century, for agricultural labour was paid at about *3d.* a day, in other words at *9d.* of our present money, and the price of wheat as contrasted with the price of labour was disproportionately high in those ancient times. The sole cause of the increase of rent is to be found in the diminished cost of production, the correction implied by a sustained demand contributing to rent, but being a condition rather than a cause. Not only, indeed, is it not the case that diminished cost of production diminishes rent, but the facts of economical history prove the increase in rents to be due to this cause alone; and not only, again, is it not true historically that the exigencies of population have led to the cultivation of inferior soils, but it may be doubted whether the amount of land cultivated in grain crops at the present time is much more than that which was under the plough in the age referred to above, i.e. 500 years ago. The exigencies of population, concurrently with the desire of larger profits, *present and operative in those only who are at once owners and occupiers*, have led to agricultural inventions which have diminished cost and increased production, and thus rendered it possible that tenants should be forced to adopt improvements which they would never have searched for or applied as mere tenants. By these causes rents have been enhanced, and are still increasing in just the same proportion as the cost of production is diminished. Nor is rent affected by the comparative cheapness of wheat since the abolition of the corn laws. For, agricultural produce being very various, and the margin left to wages increasing when bread is cheap, the income of the labourer is larger and more available for the consumption of other products, as meat, poultry, wool, and the like.

It was not remarkable that, at the time when Malthus wrote, the partial view of the truth as regards rent should have been propounded and accepted. It must be remembered that it was a time of severe general distress, in which every economical principle was steadily ignored by the government of the day, and the expense and insulation of a great war had made it necessary that this country should depend almost entirely on its own resources for the sustenance of the people. To these circumstances must be attributed the cultivation of tracts which had not been broken up for centuries, and the activity given to the production of cereals, the rise in rents consequent upon the profits of enormous famine prices at home, and the machinery of the corn laws, intended avowedly to stereotype high prices and large rents, on the false and foolish plea of the peculiar burdens on land. Had the economists who accepted the popular view of rent, been at the pains to investigate the facts of one period of English economical history, and to contrast it with that which they knew familiarly, they would have seen cause so far to modify their theory as to have recognised the fact that rents do not fall with improvements in the process of production; they would have seen that the

interest of the agriculturist and landlord was not antagonistic to that of the general public, and would have learnt that the same rule holds good in agriculture as in trade, that the higher the profit and the less the expense of the calling, the larger is the margin left for that payment in consideration of a *locus standi* for industrial occupation which we call rent.

But while rents rise as the cost of produce in demand diminishes, they would fall if one part of the cost of production were increased, that, namely, of the wages of labour. It is true that the real rise in the wages of the agricultural labourer, which has succeeded the new poor law, and the establishment of free trade in corn, has not been attended by a fall in rents, but by the contrary phenomenon. But this result is due to the enhanced value of all agricultural produce other than wheat, and by the greater produce at less cost—circumstances which have far more than counterpoised the small rise in the rate of agricultural wages, amounting probably to not more than ten or fifteen per cent. If hereafter the mass of agricultural labourers get and use the information which might be supplied them, as to what are the only means for bettering their condition, if they could learn that early and imprudent marriages have the effect of so tying them hand and foot to their employment as to reduce their wages to the lowest point compatible with a bare existence, and that the charity of the poor rate is a very doubtful boon, they might hereafter assume a position of greater independence and hope. In the counties of Cumberland and Westmoreland, where agricultural wages reach the highest rate, the cause is to be found in the fact that the labourer is always provided with the means of emigration, and that he uses these means instantly if there be a threatened reduction of wages in his neighbourhood. Were agricultural wages increased fifty per cent. it is possible that rents would be, for a time, diminished, though the increased demand for produce would in all likelihood speedily bring about a recovery.

Rent does not raise or depress prices, as some persons have imagined, for the cause of rent and the cause of price are governed by a totally different set of facts. The price of a commodity depends on its cost, and the demand for the article; rent depends upon the amount produced on a given area, the equality of rates of profit necessitating that rent should be paid out of the excess of produce. That rents do not affect prices is manifest at once if we illustrate the fact by a supposed case. The instantaneous annihilation of rents would not cheapen food, but would simply transfer the rent hitherto paid to the landlord into the pocket of the cultivator. No one is richer or poorer because the landlord obtains a rent, for the price of produce is due to the demand for the commodity; and the general public, i.e. the consumer, is in no way interested in the distribution of the parts of that which he must needs pay by the competition of purchasers. But this general statement must be guarded by an explanation. Prices may indirectly be enhanced by the limitations or restrictions put upon the occupation of land. The general public is interested in the largest amount possible being derived from the soil, and any hindrance laid on production is therefore a national loss. For instance, if a system of long leases enabled the farmer to produce one-third more meat and corn, it is a matter of the greatest importance to the public that such a state of things should be brought about. It would be, of course, equally an advantage to the landowner, whose interests are inseparably united with the general good of the community. So if restrictions or hindrances are put upon the occupation of land for building purposes, the general public is affected because the area available for a purpose of great importance to society is artificially narrowed. Rent does not, we repeat, increase prices; but peculiar tenures of land, and difficulties put in the way of its distribution, may and do raise prices, by creating scarcity. So, again, the excessive preservation of such game as is destructive to crops is a public nuisance and a national loss.

Much greater prominence is given by English economists to the theory of rent, than is assigned to it by foreign writers. This arises from the fact that the British islands are nearly the only part of the world in which the owner of the soil and the occupier are different persons. Hence that which with foreign economists would be the question of the relation of population to the means of subsistence, is among English writers the question of the principle which governs the amount of the produce received by the owner of the soil. Of course, in effect rent is paid in other countries as well as in this, only it is under a different shape. That it is so, is manifest from the fact already adverted to, that the natural powers of the soil are as freely mortgaged or pledged in other countries as they are in this. And when land is sold, its price follows the rate of interest, being generally rather more than the capitalised value of a perpetual annuity, because it confers social rank, and is susceptible of indefinite increase in value. In foreign countries, too, the fact that the majority of the people are engaged in agriculture, enhances the cost of such parcels as are brought into the market. Rents of particular sites of agricultural land are sometimes very high, as in England of the rich hop lands of the vale of Farnham and some parts of Kent, and in France of those estates which are distinguished for the produce of such wines as bear high prices. The best French vineyards are frequently sold at the rate of a thousand pounds an acre; and of course if such vineyards were let, they would bear a corresponding rent.

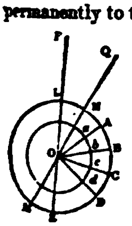
Rents in other countries than this are of many various kinds. For an account of each, see COTTIER, CONACRE, LABOUR RENTS, MÉTAYER, SERF, and RYOT. For the effect of a tax on rents, see TAXATION.

Besides the attention which has been given to rent by such writers as have discussed the principles of political economy, special pains have been taken with this subject by Malthus, Ricardo, and Jones. No modern economist has devoted more pains than the last-named writer to the general theory of rent, and to the various forms in which rent appears. The views of Mr. Jones are to be found in his work on Rent, and in his literary remains, which have been collected by Dr. Whewell.

Repeat (Fr. répéter, Lat. repeto). In Music, a character 𝄋 denoting the repetition of the part which it bounds. It is sometimes expressed by dots against the bar, and sometimes by the words *dal segno*.

Repeating Circle. In order to diminish the effect of errors of graduation, and to obtain very accurate measurements by means of comparatively small and therefore portable instruments, a method of observing was invented, or rather brought into use, by Borda, which is now extensively employed, especially in geodetical operations. The method, which consists in moving the telescope successively over portions of the graduated limb corresponding to the angle to be measured, and reading only the multiple arc, may be advantageously applied to circular instruments destined for very different purposes; as, for example, to an instrument for the measurement of the zenith distances of stars or terrestrial objects, or the distance of two trigonometrical stations, in which case it is simply called a *repeating circle*; to a reflecting circle used for observations at sea, when it becomes a *repeating reflecting circle*; or to a theodolite, when it becomes a *repeating theodolite*.

For the purpose of giving an idea of the principle of this method, we borrow the following illustration from Sir J. Herschel: 'Let P Q be two objects, which we may suppose fixed for purposes of mere explanation; and let K L be a telescope movable on O, the common axis of two circles, A M L and A B C, of which the former, A M L, is absolutely fixed in the plane of the objects, and carries the graduations freely movable on the axis. The telescope is attached permanently to the latter circle, and moves with it. An arm, O *a* A, carries the index or vernier, which reads off the graduated limb of the fixed circle. This arm is provided with two clamps, by which it can be temporarily connected with either circle, and detached at pleasure. Suppose now the telescope directed to P. Clamp the index O A to the *inner* circle, and unclamp it from the outer, and read off; then carry the telescope round to the other object Q. In so doing, the inner circle, and the index arm, which is clamped to it, will also be carried round over an arc A B on the graduated limb of the outer circle equal to the angle P O Q. Now clamp the index to the *outer* circle, and unclamp the inner, and read off. The difference of readings will, of course, measure the angle



P O Q; but the result will be liable to two sources of error, that of graduation and that of observation, both of which it is our object to get rid of. To this end transfer the telescope back to P, *without* unclamping the outer circle; then, having made the bisection of P, clamp the arm to *b*, and unclamp it from B, and again transfer the telescope to Q, by which the arm will now be carried with it to C over a second arc B C equal to the angle P O Q. Now again read off; then will the difference between this reading and the *original* one measure *twice* the angle P O Q, affected with both errors of observation, but only with the same error of graduation as before. Let this process be repeated as often as we please (suppose ten times); then will the final arc A B C D read off on the circle be ten times the required angle, affected by the joint errors of all the ten observations, but only by the same constant error of graduation, which depends on the initial and final readings off alone. Now the errors of observation, when numerous, tend to balance and destroy one another: so that, if sufficiently multiplied, their influence will disappear from the result. There remains, then, only the constant error of graduation, which comes to be divided in the final result by the number of observations, and is therefore diminished in its influence to one-tenth of its possible amount, or to less if need be.' ('Astronomy,' *Cabinet Cyclopædia*, p. 105.)

When the repeating circle is used for measuring zenith distances, it is constructed so as to be capable of being turned round on a vertical pivot, the direction of which passes through its centre, and to which its plane is parallel, and also of turning in its own plane about a horizontal axis. The instrument being placed in the same vertical plane with the star, the telescope is directed to the star and the bisection made; the telescope, which carries the verniers with it, is then firmly clamped to the circle, and the circle turned round 180° in azimuth about the vertical pivot. If the circle be now kept fast, the telescope unclamped and carried round till the star is again bisected, it is plain that the arc of the limb passed over by the verniers in consequence of this motion of the telescope will be double the zenith distance of the star. The same process is repeated as often as may be thought necessary. For the purpose of geodetical measurements the circle is usually furnished with two telescopes, one on the face, and the other on the back; and so placed that the optical axes of both are exactly in the plane of the circle. The circles used by Mechain and Delambre, in the operations connected with the measurement of the French arc of meridian, were about four-tenths of a mètre (nearly 16 in.) in diameter, and were divided into arcs equivalent to about 32 sexagesimal seconds, which were subdivided into tenths by the verniers.

The merit of first applying the ingenious principle of repetition to angular measurements belongs to Tobias Mayer; but it was Borda, as above stated, who first brought the instrument into general use.

For a description of the repeating circle, its adjustments, and the method of using it, see Biot, *Astronomie Physique*, tome i.; Delambre, *Astronomie*, or *Base Métrique*, tome i.; Puissant, *Traité de Géodésie*; Raper's *Practice of Navigation*, &c. The comparative advantages and defects of the instrument are very clearly stated in a paper by Troughton in the first volume of the *Memoirs of the Royal Astronomical Society*.

Repellents (Lat. repello, *I drive back*). Applications to the surface of the body which appear to make disorders retreat inwards.

Repelling Power. [REPULSION.]

Repent (Lat. repens, part. of repo, *I creep*). In Botany, a term applied to stems which lie flat upon the ground, and emit roots from their under surface.

REPENT. In Zoology, this term is used in the same sense as creeping, and is applied to those animals which move with the body close to the ground, either without the aid of legs, or by means of more than four pairs of short legs.

Repetend (Lat. repetendus, part. of repeto, *I renew* or *go over again*). In Arithmetic, a term sometimes used to denote the part of a circulating decimal which is continually repeated.

Repleader. In Law, repleader is awarded in some cases when, after issue in an action is joined and verdict given thereon, it is found that by mistake issue has been joined on a fact totally immaterial and insufficient to determine the right, so that the court upon the finding cannot know for whom judgment ought to be given. In such case the court will sometimes award a repleader (quod partes replacitent), the effect of which is that the pleadings begin again de novo at that stage of them in which the error happened. [PLEADING.]

Replevin. In Law, an action of tort, in which the plaintiff seeks the recovery of goods illegally distrained. Since 19 & 20 Vict. c. 108 the proceedings can be commenced in the county courts. [ACTION.]

Replication (Lat. replicatio). In Law, the third stage in the pleadings in an action, being the plaintiff's answer to the defendant's plea. [PLEADING.]

Replum (Lat.). In Botany, a term applied to the frame left in certain fruits by the falling away of the valves, as in the siliques and silicles of the *Cruciferæ*.

Reports (Lat. reporto, *I bring back*). In Law, statements of adjudged cases in the several courts of law and equity which form precedents for future decisions. In earlier times the reports were published by authority, but this series (which is known by the name of the *Year-books*) was discontinued in the reign of Henry VIII., since which period the compilation and publication of the authoritative decisions of the courts has been conducted by private persons on their own responsibility. An attempt to restore official reporting was made by Lord Bacon, and an ordinance to that effect was obtained from James I.; but only one reporter, Hetley, seems ever to have been appointed under it. The place of the year-books was, however, soon supplied by other reports. These at first were merely notes of adjudged cases taken by lawyers for their own use, and published long after the cases were decided. There seems to have been a doubt, which (as appears from the preface to Sir James Burrow's reports) was subsisting so recently as 1765, whether the unauthorised publication of the daily proceedings of a court of justice might not be a contempt of court. Contemporaneous reports of the decisions in all the courts have, however, now been regularly published for a great number of years. The volumes of reports amount at present (1866) to nearly 1,200 in number, and the yearly increase lately has been from twenty to thirty volumes. Up to the close of 1865 the decisions in every court were separately reported in a regular series; but besides the regular reports of each court there were five or six legal publications, coming out weekly or monthly, and professing to give reports of the decisions in all the courts. The latter publications are sometimes termed *unauthorised reports*, in distinction from the regular or authorised reports; but in fact the regular reports possess no special privilege or authority except that some judges have viewed them with more favour than other reports, and given their authors occasional assistance in the way of lending written judgments, revising proof-sheets, and the like. It is, however, understood that any report of a case published with the name of a barrister annexed to it is accredited, and may be cited as an authority, although as a matter of practice the regular reports (as having been published with greater care and deliberation) are usually cited in preference to the other reports when the same cases appear in both. All the reporters have reported or omitted such cases as they respectively thought fit without control from any superior authority, and it has frequently happened that the reports have been some years in arrear. The cost of taking in the reports has formed a serious item in the professional expenses of every barrister, several of the competing series having usually been taken lest any case should be overlooked.

An attempt has recently been made on the part of the bar to procure the consolidation of the regular reports into a uniform series, to be published at a reasonable price, under the supervision of competent editors and the general superintendence of a council selected from the leading members of the legal profession; and this movement seems likely to be successful in removing the principal evils attending the system of law reporting as hitherto conducted.

Repose (Fr. repos, from Lat. repono, *I lay down*). In the Fine Arts, the absence of that agitation which is induced by the scattering and division of a subject into too many unconnected parts, in which case a work is said to want repose. Where repose is wanting from this cause, 'the eye,' says Sir Joshua

Reynolds, 'is perplexed and fatigued, from not knowing where to rest, where to find the principal action, or which is the principal figure; for where all are making equal pretensions to notice, all are in danger of neglect.'

Repose, Angle of. In Engineering, the term *angle of repose* is frequently applied to express the angle at which the various kinds of earth will permanently stand, when abandoned to themselves. The knowledge of the limits of this angle will be found essential to the engineer who is charged with the execution of large cuttings, or embankments, or who may have to execute retaining walls, or other structures of a like nature. The reader who may desire to study this question in detail, is referred to Rondelet, *L'Art de Bâtir*; to Mayniel, *Traité de la Poussée des Terres*; to Barlow's *Essay on the Strength and Stress of Timber*; Pasley's *Course of Military Instruction*; and to Parnell's *Treatise on Roads*. It appears, from the authors cited, that the earths mentioned below will stand at the angles quoted opposite to them, if only they be of an even nature and without intermixture of strata that would give passage to the waters. It is for this reason, the probability, namely, of the occurrence of a mixture of sand with the general body of the formation, that in practice it is safer to count upon the various earths standing at the angles quoted against them.

Nature of Earth	Angle	Slope of Base to Height
Fine dry sand, of pulverised sandstone	$34\frac{1}{2}°$	about $1\frac{1}{2}$ to 1
Ordinary earth, dry . . .	46·50°	
Ordinary earth, lightly wetted .	54°	
Shingle, comparatively speaking dry	49°	
London clay, very variable, much sand	. .	3 to 1
Chalk, or chalk marl . . .	. .	1 to 1
Sandstone, firm, hard, and uniform	. .	$\frac{1}{2}$ to 1
Limestone	. .	$\frac{1}{4}$ to 1
Granite, or the primary rocks .	. .	$\frac{1}{8}$ to 1

Generally speaking, it is considered safer to make the slopes of all new embankments $1\frac{1}{2}$ in base to 1 in height, excepting where they are executed in clay, which is thrown out with a slope of 2 to 1 as a minimum. The slope which the earthwork would assume at the back of a retaining wall of a river will be always affected by the infiltration of the water from the river, which will mount up in the pores of the material by capillary action. Hence the actual thickness given to retaining walls is much greater than that which the theory demands. Having to resist, in fact, the thrust of a substance which is a semifluid heavier than water, they are usually made of half their height in their average thickness. [Quay Wall.]

The term *angle of repose* is also used, in works upon Mechanics, to express the angle at which the effect of gravity is capable of overcoming the friction which the relative surfaces of the bodies in contact exercise on one another; or, in other words, the angle at which those substances would begin to move, as in an arch, it being supposed that each of them is homogeneous, and that its particles are incapable of moving one over the other. This may be calculated at about 60° from the perpendicular to the horizon; but very much will depend upon the adhesion of the cement employed between the stones or bricks that enter into the composition of the arch; so much so as in fact to render all abstract reasoning with respect to the stability of arches executed in small materials and cement utterly valueless. The conditions of the stability of an arch will be found discussed in Moseley's *Engineering and Architecture*, or in Claudel's *Formules à l'Usage des Ingénieurs*.

Representation (Lat. repræsentatio, from præsens, *present*). In Painting and the other Arts, the transference to a plane of a solid mass, or the appearance of an object to the eye.

Representation. In Politics, that machinery in the system of government by which one person or a few persons are made the vehicle in expressing the opinions of a large number, with a view to action on those opinions. It is generally understood that a *representative* fulfils different functions from a *delegate*; that while the latter is empowered to carry out only a defined and distinct purpose, the former is intrusted with a general power of judgment within certain limits; that he is entitled to exercise a discretion on subjects which may become topics for political debate from time to time; and that, while he is bound in good faith to adhere to the general principles of the party or aggregate of persons for whom he speaks, he is allowed a considerable latitude of judgment, subject, of course, to the ultimate approval or condemnation of the constituents for whom he acts. Some parallel may be found in the position occupied by a plenipotentiary in diplomacy, as contrasted with that of a chargé d'affaires, or a minister with limited powers.

It is clear that the institution of a representative system must be the result of a long series of events, in the course of which it has become possible that a trust may be committed to the representative, and confidence may be reposed by the constituents. The representative system in politics has arisen from an elaborated political education of the people, by which checks upon itself and its representatives have been gradually developed, which are not indeed capable of exact definition, and are, under the pressure of occasional emergencies, shifting, but which are withal real and reciprocally comprehended. The interpretation of these obligations is facilitated by that *government by party* which is justly considered to be intimately connected with representative institutions. The general traditions of political parties are in ordinary cases a rough guide to the duty imposed on a representative; and, as a rule, a departure from the principles of the party which returns its representative, is held to be a breach of trust and an act of political immorality or perfidy. The more marked is

that departure, the more just is the criticism on the conduct, and the more necessary is apology or explanation for the action of the offender.

The political systems of the ancient world contained no theory of representation. Faint traces, it is true, of such an expedient, may be discovered in the action of the Amphictyonic council, especially in the later days of its existence, when it was rapidly being turned into an engine for the aggrandisement of the Macedonian kings. Some slight indications of representation, too, may be traced in the Ætolian and Achæan leagues; but in all these cases the powers of the federation are rather those of delegates instituted for a particular purpose, and bound to very narrow and definite functions, than of representatives who could originate a policy or deal with an emergency. For the Greeks, Mr. Grote has well remarked that 'in respect to political sovereignty, complete disunion was among their most cherished principles. The only source of supreme authority to which a Greek felt respect and attachment, was to be sought within the walls of his own city. . . . . Political disunion—sovereign authority within the city walls—thus formed a settled maxim in the Greek mind. The relation between one city and another was an international relation, not a relation subsisting between members of a common political aggregate.' (*History of Greece*, part ii. ch. ii.) Hence all transactions between one city and another can be characterised only as *interpolitical*, and the theory of a state or city implied the competence of all the citizens to take part in the government. [LIBERTY; PRIMARY ASSEMBLIES.] Thus no room was left for the modern notion of representation, and hence the attempts to turn Hellenism into a real political unity and a basis for joint operations were abortive, because the requisite machinery for joint action was wanting, and could not have been developed without long training and a number of concessions which the several states were not competent to understand, or, if competent, willing to endure.

Still less was the Roman system representative. The whole people, it seems, was summoned to give effect to certain laws, and to elect magistrates. But the executive and legislative body of ancient Rome, though derived originally from popular election, ceased, after the election was over, to be representative, because it ceased to be responsible to the electors. The Roman senate, from whom in practice the laws emanated, and to whom the administration of public affairs was intrusted, was in effect a chamber of life peers, the introduction to which chamber was accorded to all who had held particular public offices. Only a faint trace of representation is, perhaps, discovered in the influence exercised by the *tribus prærogativa*. Shortly after the institution of the empire, popular elections became a complete farce; the custom of summoning the electors fell into disuse, and was speedily abolished.

The system of representation peculiar to the western nations of Europe had a very humble origin. Historically, it is in all likelihood an imitation of the representative assemblies of the clergy, among whom, for obvious reasons, the practice of delegating certain members of the body to speak for the whole, in general and local councils, was early adopted. But as far as regards assemblies of the laity, it appears that the origin of the modern system is to be found in the fiscal necessities of the sovereign.

At about the commencement of the thirteenth century, an important change was being effected in the social condition of the people by the gradual creation of chartered towns. These towns had purchased freedom from arbitrary taxation or tallage, with the right of holding local courts of law, and of electing municipal magistrates, from the lords on whom they had previously been dependent. For various reasons they were favoured by the monarchs; and these towns grew in wealth and importance in England and France, but especially in Spain. They formed a counterpoise to the power of the feudal barons; and the protection which the king was able to accord them, was largely and gratefully repaid by grants of subsidies and other pecuniary aids.

The mechanism by which these aids were accorded to the sovereign consisted in the appointment of two burgesses or two knights, whose business it was to make the grants, and probably to assess the contribution. As they were virtually transacting business for their constituents, they were allowed wages; and as they were supposed to be acquainted with the circumstances of the town for which they appeared, they were generally selected from the residents in the town. When in course of time it became an object of some ambition, and perhaps (in consideration of the wages paid) of advantage to sit for boroughs in parliament, an attempt was made to limit the election to such as resided in the represented borough; but the Act fell speedily into desuetude, if indeed it was ever acted on.

The settled principle of constitutional law, that no tax could be levied without the consent of the taxpayer, originally affirmed in the Great Charter, and perpetually confirmed by renewals of the charter, and the practice of government, made the frequent summons of these parliaments necessary. The demands of the monarchs almost necessitated the license of debate, at least on the grounds for which the grant was required. On this right of debate followed the right of petition, of the concession of the prayers contained in these petitions, of the embodiment of such petitions as were conceded in a formal statute, and ultimately of the power of originating statutes. Nor can it be doubted that as these appeals to the crown formed, soon after the regular summons of parliaments, a large portion of their business, the local representatives were from early times intrusted with the duty of making these petitions, and that there was some preliminary discussion in the municipal bodies as to the

terms in which petitions should be presented, and as to the claims which should be made in consideration of the grants accorded to the king. The events, then, it may be repeated, under which the representative system has been developed are so numerous, and have been so continuous, that the method now elaborated in this country and in others which have sprung from it is the result of a political education extended back into the history of nearly six centuries, a slow and steady growth of national habit.

From a variety of causes, too numerous to be noticed in an article like the present, increasing importance was annexed to the office of a parliamentary representative from as early a date as the middle of the fourteenth century; and by implication the relations of the member of parliament to his constituents, though never formally defined, have become more precise and intelligible. Considerable safeguards to an abuse of the power possessed by representatives are found in the right of public meeting, in the criticism of the local and metropolitan press, and in the practice, now become general, in boroughs at least, that during his tenure the member should meet his constituents and explain his action on points of public policy.

As the origin of the representative system is to be found in the necessity laid on the monarch of appealing to the people for aid in his fiscal exigencies, so it was the policy of the kings to accord the privilege of parliamentary representation to all towns in which any trade or manufacture was carried on. Hence the representation of the boroughs was far more copious than that of the counties, all of which latter sent two members, and two only. It is certain that in early times, at least, the towns which were admitted to the borough franchise had some local importance. Thus the Cornish towns were important for their trade in metals, especially in tin; the Dorsetshire and Wiltshire boroughs were the local centres of the cloth trade; those of Surrey and Sussex were marts for manufactured iron, at that time chiefly produced in the south of England; and so on. In course of time the trade migrated, and the towns declined. The power hitherto assumed by the king of creating new boroughs by charter was checked at the beginning of the reign of Charles I.

In course of time many of these boroughs sank into complete decay, while others not represented in parliament grew into great cities. Thus, while Birmingham and Manchester sent no members, Old Sarum and Gatton, which had actually ceased to exist, sent two members apiece. Again, the right of suffrage was in many cases shared by a few persons, or even monopolised by an individual. Thus during a part of the eighteenth century one person sent both members for the borough of Helston. Many of these anomalies were remedied by the Reform Act of 1832, which, although an affair of compromises, may be held to have recognised to a limited extent the principle that population, taxation, and representation should be relative, and certainly made it impossible that there should be any final settlement of the representative system, as long as there is any discrepancy between the proportions in which these political conditions stand to each other.

The theory that representation should be based on numbers, when once the tradition of a permanent right to send members from any given place (whether large or small) was invaded, is logical and ultimately inevitable. As long as the privilege of the ancient boroughs was respected and maintained, it was possible to vindicate on certain grounds, whatever they were worth, the system of nomination, or as they were called, more familiarly (for party names are seldom elegant or courteous), rotten boroughs. But when once the defence was forced, though it might still be possible to delay the capitulation, the maintenance of any other representative theory than that which is based on numbers became a mere question of time, and the surrender, if the representation is a matter of public interest (i. e. of that interest which is essential to national vitality), was felt to be scientifically necessary. It is needless to say, that this necessity is quite distinct from any theory as to what should constitute the franchise or right of voting. In other words, that which is called the *redistribution of seats* is one thing, the *extension of the suffrage* is another. The latter may be a matter of debate, the former can be delayed only by the force of particular influence. [SUFFRAGE.]

Of late years the theory of representation in parliament has been coupled with some other questions; and first as to the best means of giving effect to the opinion of the minority. This question presupposes two postulates, universal suffrage and numerical representation. As long as there exists an unequal value in the votes given by electors, so long is the numerical minority represented in the return; and similarly, as long as any person of competent age and education, who is not chargeable with crime, and not a claimant for a public maintenance out of poor rates, is excluded from the franchise, so long the social minority is more than adequately represented. Hence the theory of representing minorities, in the hands of its ablest advocate, Mr. Mill, includes by logical necessity the representation of women.

The means by which it is suggested that minorities may be represented are generally two. One of these is that of giving two votes to each elector when three candidates can be returned, or one vote when two are to be elected. Such a system has been adopted in the election of the several members who constitute the council in the university of Oxford. It certainly secures that the minority should appear in the governing body, and that the views entertained by such a minority should gain a hearing in debate. But of course it does not secure more than a hearing. The

action will still be directed by the majority, and the hearing might be just as effectual outside as inside the deliberative body.

Another method, suggested by Mr. Hare and supported by Mr. Mill, is that which gives the elector an option in choosing the constituency in which to record his vote. Here it is manifest that the conditions adverted to above, viz. universal suffrage and numerical representation, must be conceded in order to give the plan even the appearance of fairness. If an elector could choose his own constituency, and if constituencies having equal numbers of representives varied in size, it would be possible by transferring votes to the smaller constituency to give the minority the power of a majority.

It may be doubted, however, whether the disadvantages supposed to affect a minority are not rather apparent than real. No one intends, we may suppose, to give a minority more than a fair hearing and a right of protest. But this appears to be effectually accorded by the machinery of an election, and still more by the abundant means, under the conditions and conveniences of modern civilisation, which exist for the promulgation of political opinions through the press and by public meeting. There seems to be no disposition on the part of the majority to oppress the minority; on the contrary, the course of history indicates that the reverse process has been generally exhibited, and that governments have frequently subsisted on active and well-organised minorities.

The chief objection to the parliamentary representation of minorities (of course they are invariably present in parliament by indirect means) is that it takes away from the electors the disposition to political debate, and tends to insulate political opinion from the healthy atmosphere of competition. If an elector is empowered to register his vote in a locality which accepts his opinions as foregone conclusions, he will be at no pains to interpret these opinions by any other standard than that of his own prejudices. This is in itself an evil. Besides, it may be urged, that of all kinds of education, that which cultivates the reflective and logical faculties is the most valuable, and that to the mass of men no set of facts is more available for this culture than debate on such large questions of political, social, and economical interest as are and will be the objects of parliamentary judgment and action. Furthermore, it is of no small value and of no little economy to government and to parliament that such questions should be ventilated out of doors, and perhaps no better means could be devised for the complete cessation of such a contest of opinion as is implied in general debate, than the concession of the privilege of recording a vote in quarters which would leave the question undebated, because virtually settled. Lastly, it would throw the whole onus of argument on parliament and the press, would tend to make the decision of the former more difficult and more slow, and would exaggerate that special evil of our own time, the disposition on the part of the general public to accept, as a relief from the trouble of thinking, the irresponsible expression of anonymous political writers, the special pleading of the worst kind of advocates.

Representation of Classes.—Some modern political writers, among whom we may quote Lord Grey, have advocated the view that certain constituencies should be so arranged that the members of parliament from them should represent certain interests. In this way it is supposed that the various interests would get a fair hearing, and that parliamentary action would be facilitated. Such a representation does exist to a limited degree in the members for the universities. It may be added that the parliamentary constitution of Sweden is entirely in accordance with this principle.

It may be feared, however, that such an expedient would defeat its own ends. Parliament, if it fulfils its duty, exists in order to harmonise, not to stereotype and insulate classes; to deal with common interests, not to be split up into juntos which shall watch over particular interests. At the present time, and under its existing constitution, the commonest reproach against parliament is, that in addition to the two great divisions inseparable from the system of political action, those which have been called the party of progress and the party of order, the House of Commons has an infinity of subordinate parties. Thus, we hear of the Railway party, the Irish party, the Catholic party, the landed interest party, &c. Now if this division is an evil, why add to it? Still more, why turn an acknowledged hindrance, whose existence is indirect, into the machinery of the constitution, to be invested with a direct and recognised existence? The acceptance of such a scheme would probably involve inconceivable confusion, and bring matters rapidly to a dead lock.

Representation by Accumulation.—In trading companies, the possessor of the larger amount of shares has generally a proportionate amount of votes. It has been argued that the same rule should be extended to political interests, and that the possessor of large property, having a larger interest than he who has little, should be endowed with larger influence in the conduct of government. Such a theory, in the first place, accepts the position that property or wealth is comprised in material objects only, a position which is certainly open to dispute. It further takes for granted that the sole object of government is the preservation of property, whereas it is just as much, perhaps even more, concerned in the preservation of that order by which life and its lawful enjoyments are secured and labour is exercised. It may be doubted, too, whether under the most democratic form of government conceivable, property would not exercise a large proportionate influence on public action and policy. Wealth represents, among other objects, the sum of desirable

things; and, coupled with the disposition to procure and admire such things, there exists, in modern society at least, the conviction that the only means by which these objects can be obtained and protected, lie in the fullest freedom of action and the largest possible defence to property.

It is impossible in so wide a subject as that of the present article, to do more than summarise the question; and it is wholly impracticable to attempt a selection from the vast mass of literature which has grown up around it.

Reprieve (from Fr. reprendre, *to take back*). In Law, the suspension of the execution of sentence on judgment in a criminal case for a certain time. Reprieve at the will of the judge is arbitrary; and the judge has power to give it where he is dissatisfied with the verdict, in order to give time to apply to the crown for a pardon. Reprieve is also ex necessitate legis; as, a woman capitally convicted has a right to a reprieve during pregnancy; or when a party becomes insane between judgment and award of execution.

Reprisal. In National Law, reprisal is the capture of property belonging to the subjects of a foreign power in satisfaction of losses sustained by a citizen of the capturing state. [MARQUE.] Letters of reprisal are grantable by the law of nations, where the subject of one state has been oppressed or injured by the subjects of another, and where justice has been refused on application by letters of request. The mode of serving out letters of marque and reprisal in time of truce was regulated by stat. 4 Hen. V. c. 7, but this has been long disused. The power of granting letters of marque and reprisal has been given by statute, and sometimes by proclamation, to the lords of the Admiralty. [PRIVATEER.]

Reprises (Fr. reprise). In Law, deductions or payments out of the value of lands, such as rent charges or annuities.

Reprobation (Lat. reprobatio). In Theology, a term commonly applied to the supralapsarian tenet of the consignment of all mankind to eternal punishment, with the exception of those whom God has arbitrarily selected for eternal happiness. [ELECTION; PREDESTINATION.]

Reproduction (from Lat. re, and produco, *I draw forth*). In Physiology, this word is sometimes used for *generation*; but it signifies properly the power which a fully developed organised being possesses to push forth and form anew parts of the body which have been cut off. Vegetables possess this faculty in an eminent degree, and animals have the power of reproduction in proportion as they resemble vegetables in the simplicity of their organisation; thus the freshwater polype *Hydra viridis*, when divided into many pieces, reproduces all its characteristic organs out of each piece. Worms and other Annelides can reproduce many segments of the body. Snails can push forth new horns, and reproduce even a great part of the head. Lobsters and spiders thus gain new claws or legs. Newts and lizards reproduce their tails.

Reptation (Lat. reptatio, *a crawling*). A mode of progression by advancing successively parts of the trunk, which occupy the place of the anterior parts which are carried forwards, as in serpents. The term is also applied to the slow progression of those animals whose extremities are so short that the body touches the ground.

Reptiles (Lat. reptilia, from repo, *I creep*). The name of a class of cold-blooded Vertebrate animals, including all those which have lungs, and a heart composed of two auricles and one ventricle. Those which retain their gills during the whole or a part of their existence are termed *Batrachians* or *Amphibia*: the latter name Linnæus applied to the whole group, as well as to certain true fishes [AMPHIBIANS; BATRACHIANS; CHELONIANS; OPHIDIANS; SAURIANS.] Cuvier, in characterising the class of reptiles as defined by him, well observes, that as it is from respiration that the blood derives its heat, and the muscular fibre its susceptibility of nervous irritation, the blood of reptiles is cold, and the muscular energy less than that of quadrupeds, and much less than that of birds. Thus we find their movements usually confined to crawling and swimming; for though at certain times several of them jump and run with considerable activity, their habits are generally lazy, their digestion excessively slow, and their sensations obtuse. In cold or temperate climates, almost all of them pass the winter in a state of torpor. Their brain, which is proportionally very small, is not so essentially requisite to the exercise of their animal and vital faculties as to the members of the first two classes: their sensations seem to be less referred to a common centre, for they continue to live and to exhibit voluntary motions long after losing their brain, and even after the loss of their head. A communication with the nervous system is also much less necessary to the contraction of their fibres, and their muscles preserve their irritability after being severed from the body much longer than those of the preceding classes: their heart continues to pulsate for hours after it has been torn away, nor does its loss prevent the body from moving for a long time. The blood-discs are elliptic and nucleate, and relatively larger than in fishes. Batrachians show a marked difference from plagiostomes in this particular.

The smallness of the pulmonary vessels, and the relations of their trunk to the heart, permit reptiles to suspend the process of respiration, without arresting the course of the blood; thus they dive with more facility, and remain longer under water, than either the Mammalia or birds.

Few reptiles hatch their eggs: still fewer bring forth living young. The Batrachians on quitting the egg have the form and branchiæ of fishes, and some of the genera preserve these organs even after the developement of their lungs.

The quantity of respiration in reptiles is not fixed, like that of the mammals and birds, but varies with the proportion of the diameter of the pulmonary artery compared to that of the aorta. Thus tortoises and lizards respire more than frogs, &c.; and hence a much greater difference of sensibility and energy is manifested in this class than can exist between one mammal and another, or between birds. [HERPETOLOGY.]

Republic (Lat. respublica, *commonwealth*). That form of government in which the supreme power is vested in the people. A republic may be either an aristocracy or a democracy: the supreme power, in the former, being consigned to the nobles or a few privileged individuals, as was formerly the case in Venice and Genoa; while, in the latter, it is placed in the hands of rulers chosen by and from the whole body of the people, or by their representatives assembled in a congress or national assembly. The free towns of the Continent, Hamburg, Frankfort, Lübeck, and Bremen [HANSA], are instances of this latter form of government, as are also the United States, and some of the South American confederations. France has twice declared itself a republic, and each time the republic has been displaced by an empire. [FEDERAL GOVERNMENT; PRIMARY ASSEMBLIES; SLAVERY.]

Republication of Wills. In Law, an avowed renewal of a will; as by codicil. [WILL.]

Repudiation (Lat. repudiatio, *a rejection*). It has sometimes happened that an administration has formally declined to be bound by the debts of the governments which have preceded it; it has frequently happened that administrations have neglected to pay interest on debts which have been contracted. The former of these acts is called *repudiation*. It is said by Hallam that when the old Pretender landed in Scotland in 1715, he was ill advised enough to throw some doubt, in one of his proclamations, on the obligation of the national debt, and that consequently even those of his own party among the moneyed classes were discouraged from giving him any assistance. There is hardly a single European state which has not either annihilated a portion of its debt, or converted it into a lower denomination, or liquidated over issues of government paper by creating a capital stock on which interest was to be paid according to the metallic value of its issues at the time of their conversion into stock.

Repudiation proper, i. e. the distinct disavowal of public obligations, has been practised by several of the states composing the American Union, the most shameless examples of these acts having been exhibited by the states of Mississippi and Pennsylvania. By the peculiar constitution of the American Union great facilities were afforded for such violations of public faith, for there was no police by which the acts of these communities could be coerced. For many purposes, as for borrowing money, the states are independent; in one particular among others, that, namely, of their relation to foreign governments, they act in union. But no means could be devised by which the liabilities of the state could either be shifted upon the central government, or indeed by which the finance of the state could be controlled by the general public administration. State rights enabled the communities to borrow, and state rights precluded the foreign creditor from any remedy.

Of course no direct means can ordinarily be employed to compel the liquidation of debts contracted by foreign governments, if they resolve to be dishonest. But there is a very powerful indirect means in the prohibition of any quotation of their securities on foreign state exchanges. As every administration is occasionally liable to the necessity of borrowing, a default at any period of its financial history is at once a public scandal and a serious source of financial embarrassment when the exigency arises.

Repulsion (Lat. repulsio, *a driving back*). A term sometimes applied to the force or agency which prevents particles of matter from coming into contact. That such particles are not in absolute contact is proved by many experiments. Thus, in many cases, given volumes of two different fluids form, on mixing, a volume less than the sum of the two volumes when separate; a fact explained only by supposing that the particles of the fluids have approximated more closely to each other, and therefore that before mixture there must have been more space between those particles than existed after mixture. Again, nearly all substances contract in bulk on cooling, a phenomenon evidently due to the withdrawal of a certain amount of repulsion. Newton strongly pressed a spherical mass of glass on the flat surface of a mirror, and proved that even then the two were not in contact, and that the distance between them was not less than the eighty-nine-thousandth of an inch.

Requa Batteries. An arrangement of gun-barrels somewhat similar to the *ribaudequin* of the middle ages, from which the name appears to be derived. They were much used in the attack upon Charleston by the Federal troops under General Gillmore in 1863. The following description is extracted from the report of Major Brooks, assistant engineer in those operations:—

'This rifle battery is a device for multiplying and accelerating infantry fire from rifle barrels, and appears in principle to be a substitute for a six-pounder field-gun whenever grape and canister are needed, and, to the extent of its range, case shot, over each of which it possesses greater precision and much less liability to fail in producing desirable results.

'It consists of twenty-five rifle barrels, each twenty-four inches long, arranged upon a horizontal plane and held in position upon a light field carriage by an iron frame. Upon this frame, in the rear of the barrels, is fitted a sliding bar worked by two levers (one at

each side), by which the cartridges are forced to the rear of the chambers. By a lever under the frame the barrels may be diverged so as to scatter the balls 120 yards in a distance of 1,000. The weight of the battery, complete, is 1,382 pounds.

'When served by three men, the battery is readily fired seven volleys, or 175 shots, per minute. It did not foul. Nine degrees elevation gave a range of 1,200 yards, at which distance, the barrels being diverged, the shot scattered into an effective line. Thirteen hundred yards is probably its effective range, although 2,000 yards is claimed for it. The axis of the barrels is thirty inches above the plane on which the piece stands. . . . Three infantry men, who were not thoroughly drilled, served each piece; these were fired rapidly, and apparently with good effect.

'Being breech-loading, and easily handled, scarcely any exposure above the parapet was required on the part of the gunners. . . . I feel quite satisfied that it is adapted to the defence of earthworks, particularly in a flat country, where the horizontal line of dispersion afforded by the fire of this piece is more effective than the cone of dispersion of the howitzer. It should be noted that the angle of dispersion can be varied to suit the case in this battery, which is not true of the howitzer. These properties, together with its small recoil and its loading at the breech, and lightness, are the qualities most desirable in a gun for boat service.' (*Engineer and Artillery Operations against Charleston*, Gillmore, New York, 1865.)

Request, Letters of. In Ecclesiastical Law, an instrument by which the regular judge of a cause waives or remits his own jurisdiction, under the provisions of the Statute of Citations, 23 Hen. VIII. c. 9; in which event the jurisdiction of the appellate court attaches.

Requests, Court of. 1. An ancient court of equity, inferior to the Court of Chancery, of which the lord privy seal was chief judge; taken away by 16 & 17 Ch. I. c. 10. 2. Local courts, termed courts of conscience or of requests, for the recovery of small demands, formerly existed in many parts of the country, having been established under special local Acts of Parliament (the first of which was stat. 1 Jas. I. c. 15), with a jurisdiction limited in each case to some particular district. In 1847 the general system of county courts was established, and the local courts of requests have been absorbed for the most part in this new jurisdiction. [COUNTY COURTS.]

Requiem. In the Roman Catholic Church, a mass performed for the repose of the souls of deceased persons. It is so called from the prayer commencing 'Requiem æternam dona eis, Domine.' The term is also applied to grand musical compositions performed on solemn occasions in honour of deceased civil or ecclesiastical dignitaries. The requiems composed by Mozart, Jomelli, and Cherubini are well known.

Reredos (Fr. arrière-dos, from Lat. dorsum, *the back*). In Ecclesiastical Architecture, a screen behind an altar. These screens in Winchester and Durham cathedrals, and in St. Albans abbey, are of great magnificence, and so large as to interfere with the general view of the choir. In conventual churches the reredos was the universal termination of the ritual presbytery.

Reree. An Indian name for *Typha angustifolia*, the leaves of which are used in the north-western provinces for making mats.

Resch Glutha. The Jewish title for the officer commonly known as the Prince of the Captivity. (Milman, *History of the Jews*, book xix.)

Rescripts (Lat. rescriptus, part. of rescribo, *I write back*). In the Civil Law, answers of popes and emperors to questions in jurisprudence propounded to them officially. Those of the Roman emperors constitute one of the authoritative sources of the civil law.

Rescue (Fr. recousse). In Law, in the more general sense, a species of resistance to lawful authority; as, by delivering one arrested out of the hands of those who have legal custody of him. In a more restricted application, the term *rescue* means the taking away and setting at liberty, against law, any distress taken for rent, or services, or damage feasant.

Resedaceæ (Reseda, one of the genera). A small natural order of Hypogynous Exogens, belonging to the Cistal alliance, and distinguished by not having tetramerous flowers, by their definite and not tetradynamous stamens, by their fruits being usually open at the point, and by their exalbuminous seeds. To this order belong the fragrant Mignonette of our gardens, *Reseda odorata*, and the dye plant called Weld, which is *Reseda Luteola*.

Reserve (Lat. reservo, *I keep back*). In Banking and Finance, that portion of his capital which a dealer in money retains in order to meet his average liabilities, and which he therefore does not employ in discounts or temporary loans. Long experience enables bankers to anticipate not only the amount of advances which they will be called on to make to their customers, but the average amount of claims which will be made upon them by their creditors when no disturbing cause, of which indeed they are sure to get early notice, has arisen. The amount retained for these recurring emergencies is, we are told, generally one-third of the bank's liabilities, when (as is the case with all prudent banking) advances are made only at short dates. Of course when an exceptional state of things occurs, the banker strengthens his reserve as far as he possibly can, by declining accommodation in some cases and by limiting the amount of his loans in all others. The natural machinery for these precautions is a rise in the rate of discount. When such emergencies arise, the customers of the bank, in order to fortify themselves against any pressure, accumulate their deposits; and consequently it is found, as a rule,

that the aggregate accounts of the customers who employ the bank as their commercial agent, and the reserve of the bank, rise and fall mutually. The necessity of a reserve is manifest. Whatever may be the assets of a bank, and however readily they may be disposed of, there is always great inconvenience and loss in negotiating the best securities in times of commercial difficulty.

Most of the specie in the country which is not needed for its circulation is, when the advantages of a sound banking system are understood by the public, left in the hands of bankers. The risks attending the habit of private hoarding are far larger than those which may arise from committing accumulations of specie and notes to a trustworthy bank; and in the case of such traders as need accommodation from banks, a private hoard would be a source of weakness rather than of strength. Hence the surplus coin and notes of this country are found in these institutions, and it is from these that extraordinary payments on foreign accounts have to be made. But while the general use of banking has general and manifest advantages, it cannot be doubted that, under the existing law which regulates issues, it renders these fluctuations in the rate of discount more considerable and more onerous, since they are mainly, if not altogether, relative to the amount of the reserve possessed by the Bank of England. The best remedy that could be devised against some of the fluctuations in the rate of discount would be found, it is believed, in the adoption of an international note currency, by which it might be possible that notes should be payable all over the civilised world at fixed rates of exchange. It does not seem that there are many more difficulties in such a system than there are in establishing a uniform currency in any single community. The reserve of the Bank of England is generally called *rest*, while the term *reserve* is employed to denote the amount of gold and notes held by the Bank, on which the demands for discount operate, and which by its increase or diminution affects the rate of discount.

Reserve. In Military language, a body of troops kept back in action, to give support when needed, or to be rallied on, in case of disaster.

Reserve. In Theology, the system according to which only that portion of the truth is set before the people, which they are regarded as able to comprehend or to receive with benefit. It is also known among Roman Catholic writers as the Economy. (Newman's *Apologia pro Vitâ suâ.*) [Discipline of the Secret.]

Reservoir (Fr.). A tank or pond in which water is collected and preserved in order to be conveyed through pipes for the supply of a town or canal, or for any other purpose.

It is often necessary to establish a means of regulating the discharge of the superficial watercourses of a district, either because the configuration of the ground presents too rapid a declivity, or is not of a nature to store the winter's rain, so as to give it forth again in the summer; or because the length of the valleys is not sufficient to allow of the collection of a sufficient number of rills, or subsidiary watercourses, to constitute a large river. All these conditions occur in the north of England especially, where reservoirs are indispensable for the supply of canals and mill-dams, and to meet the wants of the great towns. In tropical countries reservoirs are chiefly required for storing water for purposes of irrigation, and in some cases they are employed to retain sufficient water to equalise the flow of rivers, so as to render them more navigable in dry seasons.

In constructing a reservoir, it is advisable to select the greatest slope that can be commanded in order to collect the largest possible quantity of rainfall in the reservoir, which should be established in the narrowest part of the gorge that the stream has formed for itself, and with a valley widening out behind; provided always that this gorge be situated in a position not exposed to the danger of communicating with the lines of underground waters, or springs, and that the bottom is not of a nature to allow the rapid absorption of the water. It is scarcely necessary to remark that water for distribution in towns must be far purer than that which is needed for the supply of a canal; but generally it may be considered that the waters collected from the primitive formations are tolerably free from the impurities commonly met with in the lower secondary formations, in the sandstones, clays, marls, and the gravels and clays of the tertiary and quaternary formations. As the nature of the soil of a valley has a great influence upon the manner in which the water is retained, great attention must be paid to its permeability and hygroscopic character. The considerations relating to this branch of the subject are connected with the chemistry of water, and they are very obscure. In the regions formed of the primary series, or of the earlier secondary series, the rocks met with are slightly permeable, to a certain depth; but they are not hygroscopic, i.e. they do not take in, and hold up the water, to give it out again when the surface of the stone is laid bare. It is in the more recent formations that the hygroscopic character is most apparent, and in these therefore the establishment of storm or flood water reservoirs is more objectionable, while there is the further danger of the rock being fissured, and thus giving rise to the occurrence of springs and underground currents of water, which so seriously affect the stability of the enclosure dams. As a general rule it is found to be better, and safer, to establish these in valleys filled in with clays derived from the decomposition of the primary formations, which are very slightly permeable. Underground communications with the strata in the lower part may possibly account for the slipping of the bank of the Dale Dyke reservoir; and, therefore, too much care cannot be taken in ascer-

taining beforehand all the characters of the strata, before exposing them to the great head of water which must be brought to bear upon them. In the north of England and in Scotland, such clays occur in great abundance; but where they are wanting, the great increase of expense renders the formation of a reservoir almost impracticable. The best strata for reservoirs are the granite, porphyries, gneiss, and quartz rock, provided that their surfaces are not covered with the detritus washed down from their eminences, or broken up by subsequent movements of the soil. The slate rocks are generally too much intersected with veins of greenstone and trap-rock to be adapted for the purpose. The old red sandstones are objectionable, as being highly absorbent, and thus giving rise to the formation of land springs; the suitableness of the carboniferous sandstones varies much on account of movements of the soil subsequent to their deposition; but if the sandstones should be covered with the clays common in this set of formations, there are few better fitted for the purpose under consideration. The new red sandstones may generally be resorted to without fear of the rupture of the bank, although its great permeability renders the rock unsatisfactory. The primary limestones are objectionable on the same grounds, but they are often resorted to, as are the lias and the oolitic formations in the parts covered with clays and marls. The subcretaceous and the cretaceous formations are generally so permeable as to be almost useless, while the tertiary formations are only partially adapted for the purpose of reservoirs, the Brent reservoir being, indeed, the only one of any size formed in the clays of the London basin. The quaternary rocks are of very variable nature, but they are not generally fitted for reservoir making, as being too permeable and depending upon the substrata to uphold the water collected in them.

In the granite, and the other primary or secondary non-absorbent rocks, it is generally better to construct the dams of masonry; but whenever it can be done with economy, there can be no reason to adopt any other course than that of forming these dams in earthwork. In most of the French embankments for the supply of the canals, the reservoirs are closed by walls, and the irrigation reservoirs of Spain are mostly of the same description; in England, however, we have few reservoirs which are not formed with earthen dams, walls being seldom used for the purpose. The construction of such walls gives rise to dangers which must be carefully guarded against; but when the requisite precautions have been taken, there seem to be many reasons for preferring walls to earthwork, as they can be built more upright (and therefore with less surface exposed to the water), while, from not occupying so large a space as the earthwork, dams may be raised at a less expense of room. These masonry dams admit, further, of the establishment of works required to clear the bottom from the accumulation of débris and alluvial matter. The reservoirs of Alicante, Lorca, Almansa, &c., may be cited as illustrations of the necessity of constructing walls for such purposes.

The preliminary soundings of the valleys are of the greatest importance, and too great care cannot be paid to the indications thus afforded. The dam of the Estrecho de Rientes may be adduced as an example. In this case, the valley situated a little above the town of Lorca was barred by a dam destined to hold up the water to the height of 167 feet, and this enormous quantity of water was actually retained in the reservoir at the time of its bursting. The catastrophe was caused by the water finding its way through the sand and gravel at the bottom of the valley, which had been carelessly and hastily sounded. The consequence was that the wall was broken, and a large tunnel, about 100 feet high and 70 feet broad, was formed in the deepest part of the enclosure, through which the contents of the reservoir were emptied in the space of an hour. According to the official accounts, as many as 608 persons were drowned, amongst whom was Don Antonio Robles, the director of the works, while 809 houses were destroyed, and the damage done to real property, and to beasts and crops, was estimated at 140,000*l*., an enormous sum if we take into account the period and the value of money in Spain. This reservoir had been in use for eleven years, and might have resisted indefinitely if the height of the water had been confined to about 70 feet. On April 30, 1802, however, the waters rose to the height of 156 feet, and the wall was swept away; the bottom of the gallery by which the water was let off being the first to yield under the enormous pressure to which it was exposed without a counterbalancing weight on the inside. The lesson to be drawn from this accident is that a piled foundation can never be trusted to resist the upward pressure of a great head of water.

It is of the highest importance that the masonry of the reservoir walls should be rendered perfectly water-tight, a condition which can only be secured by the employment of hydraulic lime. It may, indeed, happen that the materials used for the masonry may be of a nature to act chemically upon the lime, as in the case of granite, which has a notable proportion of soluble felspar in its composition; but such conditions can be regarded only as happy accidents, and should never be counted upon. In the Spanish irrigation reservoirs, the walls are made with a vertical face to the water, and are executed of large ashlars. At the Rientes de Lorca, the thickness of the crown was made about 36 feet, and the slope of the surface away from the water was made at the inclination of 2 in height to 1 of base, with 4 large sets-off of 11 feet each in width. The Spaniards generally execute these reservoirs of a circular or polygonal form in plan, with the apex pointing up the stream, the resistance of the mountain being thus brought to aid that of the masonry against the pressure

of the water. The circles are struck with a radius of about 350 feet in the case of the reservoir of Alicante, one of the boldest and most successful pieces of engineering ever executed. The thickness of the wall is made, at the top, about 67 feet, the masonry batters towards the upper part of the stream 10 feet; the thickness at the bottom is 112 feet; and the difference between the top and bottom of the wall is gradually distributed throughout the height, aided by 7 sets-off that vary between 3 feet 4 inches and 1 foot 8 inches in width. It is executed in a hard primary limestone rock, and the overflow is made in two streams, each of them 6 feet wide and 7 feet below the crown of the dam, which has an inclination from the surface of the reservoir of 3 feet 4 inches. This extraordinary depth of overflow does not appear to have been too much, as the crown of the dam has been very frequently washed over in the storms which ravage the mountains where the reservoir is situated. Indeed, on September 8, 1792, the waters rose to the height of 8 feet 3 inches above the dam, and poured over it in a magnificent cascade; and the perfect manner in which the wall supported this extraordinary test has induced the inhabitants of the valley to trust entirely to the wall, and they have actually closed the overflow. The total quantity of water capable of being stored in the reservoir of Alicante is calculated at 131 millions of cubic feet. It is said that Herrera, the architect of the Escurial, was the author of this magnificent project, which was executed between the years 1579 and 1594. The height of the water, it may be remarked, is in this case, not less than 134 feet 6 inches, or greatly in excess of the depth of the Dale Dyke reservoir.

Whatever difficulties the Spanish engineers may have encountered, from the rarity of hydraulic lime in that country, there is no instance of the occurrence of a dam in earthwork upon the irrigation canals, or the derivations of rivers, executed for the supply of water to the population of towns. On the French canals, however, earthen dams are as common as the masonry walls of Spain. In England, the preference seems to have been, in all cases, accorded to the earthen dams, which are also largely employed in Italy. In India, the country where irrigation has for ages been practised on the largest scale, the earthen dams have long engaged the engineer's attention, and the failure of the dams is very rare. The surface of the country in most districts is studded with reservoirs, or tanks, as they are called, to retain the surplus rains of the monsoon; for where water is the only condition of fertility, every pint of water is valuable, as it in fact represents so much corn or other produce. Some of the Indian and Cingalese tanks are, in fact, artificial lakes, a few being as much as eight miles long; and many of these works have descended in unimpaired efficiency from a remote age. These reservoirs are almost invariably formed with dams of earthwork built across a valley. The practice of every country in the execution of such works has been, in fact, regulated partly by the local conditions with which they had to deal, and partly by considerations of economy. But besides these motives it is necessary to take into account the habits of the workmen. In England, for instance, the workmen have acquired, from long habit, a great skill in the preparation of puddle; in India, the native workmen consolidate the banks in a superior manner by their mode of carrying on the earthwork; whilst in France the execution of the walls can always be intrusted to the care of the men, who are accustomed to the use of hydraulic lime. Of late years, however, the shortness of the time now allowed for the execution of large banks in England, has somewhat modified the preference there given to the ancient style of dam-making.

The earthwork of the dams ought to be, as far as possible, executed of such materials as would exclude the water from traversing the body of the dam: it ought theoretically to be formed of a mixture of clay and gravel, which should both resist the infiltration of the water, and at the same time the boring of rats and moles. Earth so composed is seldom found, and engineers are commonly obliged to have recourse to a *puddle trench*, carried down to the foundation of the bank, and continued to about 3 feet from the top. On the resistance offered by this puddle lining (which must be regarded as a wall in the body of the bank), the success of the reservoir must depend, and there appears to be little reason for not making the thickness of the puddle trench on the average at least one-third of the height of the bank. The latter is usually made in England with an internal slope of 1 in height to 3 in base, though the French engineers have usually adopted a much steeper slope. The top of the bank is habitually made about 20 feet wide, the external slope being made at the inclination of 2 in base to 1 in height. But in all cases where these proportions have been observed, great care has been taken that the materials of which the bank is composed shall be made as homogeneous and as water-tight as possible; and the French engineers, and Mr. Leslie of the Edinburgh water-works, even prescribe that the earthworks of which the banks are formed shall be carried up in layers of not more than 4 or 6 inches in thickness, and that they shall be carefully rammed to insure their equal settlement. The French engineers take the additional precaution of watering the surface of the ground with lime water, and prescribe that the thickness of the layers shall be about 9 inches, reduced by ramming to 6 inches; but in this case they dispense with the internal puddle wall. In all cases, however, the French engineers attach great importance to the execution of the pierré, or stone pitching, which they form in separate and independent walls, so that one part shall not entail the ruin of all the rest. This system has

been applied on a large scale in the reservoirs of Torcy and Berthand on the Canal du Centre, and recently in the reservoir Montaubry.

The materials of which the banks are made must determine the profile to be given to the dam. In the Haslingden reservoir, recently completed, but not yet at work, the materials obtained in the neighbourhood were found to be composed of clay, with layers of shale, and a great deal of sand interspersed; and hence it became necessary so to increase the slope of the banks, in order to enable the earth of which they were composed to assume a permanent inclination, that at length it attained as much as 1 in 6 on the average. The same thing occurred in the Halifax water-works, where the materials employed are for the most part of a peaty nature; but in such cases the system of executing the pitching in walls susceptible of independent movements ceases to apply. In fact, the great use of the pitching is to keep up the bank when the water sinks lower in the reservoir, or is withdrawn for the purpose of examining and repairing. It would be, perhaps, more advisable to execute the pitching in independent walls if the earth be of a firm nature; but it is better to trust to the weight of the pitching to keep down the foot of the bank if the latter should have any tendency to *spew*, as the workmen phrase it; and this is effected more economically by spreading the thickness of the pitching over the whole surface of the slope thrown out to a great angle.

No definite rule seems to determine the height of the overflow, but it seems by general consent to be left at 5 feet below the top line of the bank, although there are many cases in which this height is insufficient. At the reservoir of Torcy, the waves were known to have broken and been carried to the height of 20 feet; nor can this be considered extraordinary, as the reservoir in question was at least 60 feet deep, and the wind blew directly on the greatest length. It may, therefore, be taken as a general rule, that the overflow should be executed at 7 feet below the finished line of the earthwork of the dam as at first carried into effect; because this will, in the first place, certainly sink about 2 feet in the height of 60 feet, and there is no harm in executing a little more earthwork than is strictly necessary, provided that greater security be thereby attained. The width of the overflow ought to be such that, with a flow of two feet over the crown, it should be able to discharge all the water brought down by the severest floods ever known to fall upon the basin supplying the reservoir; and this, without reference to the power of diminishing the quantity of water by the intermediate sluices. When masonry walls are used for the purpose of closing the valleys, there is less occasion to pay much attention to the size, or even to the existence, of the overflow, as the water may in such cases flow over the top of the wall, without any fear of endangering it. The Alicante dam may be cited in proof of this assertion.

Much was said about the mode of execution adopted in the case of the Dale Dyke, with respect to the pipes for drawing off the water for the supply of the town; and though it would be undoubtedly better to carry these works upon the natural foundations of the valleys, yet the event proved that no evil was inflicted by the system of artificial foundations adopted. It is, however, notorious that the pipes were laid under disadvantageous conditions; and this part of the works would unquestionably have been far better executed, if there had been a tunnel laid through the bank, which might have served to carry off the flood waters during the erection of the bank itself, and to receive the pipes destined to empty the reservoir. In France and Spain, this plan is generally adopted; and in all the canal reservoirs of the former, and the irrigation reservoirs of the latter country, there are a series of draw-off tunnels, designed to relieve the bank from the weight of water, and to draw off the supply at different levels; these tunnels being generally three in number, and placed, one alternately on each side, and the third, at the bottom level, in the very axis of the natural watercourse. If these tunnels can be executed in the firm strata of the valleys, it is of course desirable to do so; but there is no necessity for so doing, if the water can be prevented from passing along the top of the masonry or under the foundations of the tunnels, or if precautions are taken to insure that the masonry of the tunnels shall not suffer from unequal settlements of the wall or bank in which it is executed. At the barrage of Alicante the water is drawn off by a well, which occupies the inner thickness of the masonry from top to bottom, and both the gallery that leads the water to the distributing channels, and the scouring sluice, are constructed without reference to the natural surface of the ground. The height of this reservoir, at the point where the scouring sluice is placed, is 136 feet at least; so that it would appear that the position of the tunnels for the outlet of the waters depends entirely upon the manner in which they are executed, rather than upon the precise position which they may occupy. It may be added that the system adopted in the well pits and culverts of the Bradford reservoirs closely resembles that of the Spanish engineers. In this case the puddle wall was formed of less than the thickness which we have mentioned as advisable, probably because the materials of which the embankments themselves were composed were such as to allow of their being more closely packed. At any rate, the inner slope of these banks was made 3 to 1, and the outer slope $2\frac{1}{2}$ to 1; the thickness of the bank at the top being 15 feet on the average, and the height of water retained in these reservoirs being as much as 72 feet above the bottom of the outlet.

The thickness of the retaining wall or em-

bankment may be calculated upon the following principles, if the communication of the water from the upper to the lower side of the reservoir by means of springs or subterranean water-courses be totally excluded. This condition is the 'be all and the end all' of the establishment of such collections of water, and too great precautions cannot be observed to insure the attainment of it. The ground must, of course, be carefully examined, and the effects of the increased head of water must be carefully allowed for. The bottom must be such as will not absorb water, and it must have an inclination which shall not allow the water to escape or to be lost by evaporation from the surface. In fact, everything depends upon the strict impermeability of the soil employed as the foundation of the banks of reservoirs; and if this condition be not obtained, the accidents at the Torcy, the Rientes, and the Dale Dyke reservoirs will inevitably be repeated. Indeed, the dangers to which the banks or walls are exposed, can at times be so much increased by the yielding nature of their foundations, that the importance of ascertaining the nature of the latter cannot be exaggerated. Thus the foundations of the reservoir of Grosbois are upon an elastic clay; and though the thickness of the wall is calculated to resist a greater weight of water than is contained in the reservoir, yet the movement of the soil under its weight and that of the wall gives rise to corresponding movements in the masonry, which do not take place with the reservoir of Sétous, founded on the solid granite, or the reservoir of Alicante, which rests on a hard limestone.

The resistance of the bank or wall of a reservoir may be considered under three different conditions: (1) under the condition of the resistance which it may present to the forces tending to overthrow it, by causing it to turn upon the outer edge; (2) under the condition of the weight supported by the soil of the foundations, and the materials of which it is composed, which would tend to crush them; and (3) under the condition of its offering a sufficient resistance to a force that would tend to produce an effect of sliding or of friction upon the base or upon the lower courses of the masonry. In calculating the dimensions of the reservoirs, it is usual to leave out of account the weight of the parapets and of all incidental works and to consider the water as acting upon the total height of the resisting surface of the wall, without taking into account the resistance offered by the ground thrown out for the foundations. This is, perhaps, counting upon too great an effort, in many circumstances at least; but the consequences of the overthrow of a dam are so fearful, that there are no reasons why the rule should be altered to suit the few exceptional cases. In the north of England, however, it would seem that of late years care has seldom been taken to calculate the resistance of the banks, and this fact may possibly account for the failures that have cast such discredit on our engineering.

In earthen dams, it is seldom necessary to ascertain the resistance either to the effort to turn the embankment over on the outer edge, or to the effort of crushing the foundations; but the tendency of the weight to produce the movement of the bank upon the bed, and the danger that may arise from the slipping of the materials of which it is composed, must be seriously considered. It is only with reference to the resistance of walls of masonry that the considerations first mentioned begin to be of importance, for the pressure supported by a bank of earth is always less than the resistance which this bank would offer if proper care be taken in the composition of it. Thus, it has been shown by Navier (*Résumé des Leçons données à l'École des Ponts et Chaussées*) that the pressure supported by a vertical section (of infinitely small dimensions) of the height of the bank would be, on the supposition that the angle of the bank were 45°, $Q = \frac{\varpi b^2}{2}$; in which ϖ is made equal to the specific gravity of the water, while b represents the height of the water above the position considered, or, in other words, the pressure is equal to the area of the slope multiplied by the square of the height of the water divided by two. If we construct the rectangle representing the force, and apply it to the point where it would act upon the bank, i.e. at a point situated at one-third of the height from the bottom, and at the same time observing that the resultant of this pressure is normal to the line of the bank, we should see that the pressure would have a tendency to drive the bank into the earth. Decomposing this force into two other forces, of which one, n, is destroyed by the resistance of the ground to which it is perpendicular, while m represents the tendency of the bank to slip upon its base in a parallel direction to the horizon, we may thus estimate this force in a function of h. We have, in the first place, $Q = \frac{\varpi b^2}{2}$ and $2m^2 = Q^2$ for $m = n$. From this we may derive the formulæ $m^2 = \frac{\varpi^2 b^4}{4} \times \frac{1}{2}$, and $m = \frac{\varpi b^2}{2}\sqrt{\frac{1}{2}} = \varpi b^2 \times \sqrt{\frac{1}{8}}$, so that the horizontal pressure supported by the bank is equal to the square of the height of the water multiplied by the weight of unity thereof, multiplied by the square root of $\frac{1}{8}$. If, now, we suppose that the earth of which the bank is composed has the same specific gravity as the water, and at the same time that this is the only resistance to be overcome by the pressure of the water, we shall find that the resistance R, opposed to the force Q, is greater than this is; for, in fact, we have $R = fb \times \frac{1}{2}b \times \varpi$, and replacing fb by its value b,

$$R = 2b \times \tfrac{1}{2} b\varpi = b^2\varpi;$$

from which it would appear, that even upon the most unfavourable supposition the power that tends to press the bank in such a manner as to cause it to slide upon its base, is only a little more than one-third of the resistance this

would offer to it. We must, then, seek elsewhere the causes of the recent failures of reservoir banks. These causes cannot be traced to a deficiency in the quantity of materials employed; and depending as they do on the conditions of the soil and the foundations, they can hardly be the subject of strict mathematical reasoning. It is all-important, however, that the passage of the water from the upper to the lower side be prevented, not only because by this means the gravity of the bank is decreased, but also because there is a danger of the lateral displacement of the earth by the increased tendency to slip upon the bed that would be produced by the water mingling with the materials. Under these circumstances, it cannot be too often repeated that the foundations of the bank must be carried down to such a depth as shall effectually exclude any kind of communication between the strata on the two sides of it; that the bank be composed of materials capable of resisting, as far as possible, the transmission of water, and of maintaining themselves at a reasonable slope even when filled with moisture, and that the height of the crown of the dam should be made sufficiently great above the waste weir to resist the action of the waves.

The precautions to be observed with regard to the position of the by-washes, overfalls, and pipes for the supply of the water, must be regulated by the circumstances of the reservoir or by the purpose for which it is to be used. It would be dangerous to lay down any law with respect to the size, position, and details of these accessory works; and we need only remark that they must be of such dimensions and so placed as to enable the men charged with the superintendence of the reservoir always to exercise an efficient control over the water flowing into it, and never to allow the waters to become their masters. In the case of the Dale Dyke reservoir, for instance, the dimensions of the pipes laid through the bank were not large enough to carry off the whole of the flood waters brought down by the drainage of the upper lands, and the waters consequently accumulated to a height dangerous to the security of the reservoir. All this danger might have been avoided by draw-off pipes or overflows of larger dimensions, and by placing the overflows at a height which should leave the crown of the dam considerably above the flood-line. The laws which regulate the discharge of water in these cases are, of course, well known; the essential conditions of the stability of reservoir banks are connected with the foundations, and the structure of the dam itself.

Reset of Theft. In Scottish Law, the crime of receiving and retaining stolen goods knowing them to have been stolen. [RECEIVING.]

Residual Products of Gas Manufacture. The chief of these are coke, which remains in the retort after the gas has escaped, ammoniacal liquor, and tar, which separate from the gas during the passage of the latter through the condensers. Ammoniacal liquor consists chiefly of carbonate and sulphide of ammonium in aqueous solution; it is the principal source of ammoniacal salts, such as sulphate of ammonium, chloride of ammonium, &c. The tar is found as a separate heavy layer of thick oily liquid beneath the ammoniacal liquor. Its composition and uses are described under COAL TAR.

Residuary Legatee. In Law, one to whom a RESIDUE is bequeathed.

Residue (Lat. residuus, *that which remains*). In Law, the remainder of a testator's estate after payment of debts and legacies: if this remainder be bequeathed to anyone, he is styled the *residuary legatee*. If a legatee dies before the testator, the legacy is a lost or *lapsed* legacy, and sinks into the residue; and this provision of the law is extended to devises of real property by 7 Wm. IV. and 1 Vict. c. 26 (the Wills Act) s. 25. [LEGACY; WILL.]

RESIDUE. In the Theory of Numbers, the term *residue*, as applied to any given number n, and with reference to a certain modulus p, denotes any positive or negative number congruous with n for the modulus p. Thus either of the numbers 53 or -7 may be said to be a residue of the other for the modulus 5, for $53=12\times5-7$ that is $53\equiv-7$. The numbers $0, 1, 2, \ldots p-1$ are called the *minimum positive residues* for the modulus p, and any numbers respectively congruous to these are said to constitute a *complete system*. When p is a prime, any $\frac{p-1}{2}$ numbers are said to form a *half system of residues* for the modulus p; if taken positively as well as negatively, they constitute a system of residues prime to p.

The *residues of powers* of numbers, for a certain modulus, are termed respectively *quadratic, cubic, biquadratic, &c., residues*. Thus with respect to the modulus 5 the residues $9, -3, 1$ of 7^2, 3^3, 2^4 &c. would be termed, respectively, a *quadratic*, a *cubic*, and a *biquadratic* residue. The residues of powers play an important part in the theory of numbers: their properties were first investigated by Euler. (*Comment. Arith. Coll. Petropoli*, 1849.)

Resin (Gr. ῥητίνη). A proximate principle common in the vegetable kingdom, the ultimate components of which are carbon, oxygen, and hydrogen. There are many varieties of resin. Their general characters are fusibility and inflammability; solubility in alcohol, insolubility in water. They are generally separable into two distinct portions by the action of cold and of hot alcohol. They are valuable as ingredients in varnishes, and several of them are used in medicine. They are often naturally blended with modifications of gum, in which case they constitute the series of *gum resins*. The specific gravity of the resins varies between 1·0 and 1·4. They become negatively electric by friction. The commonest resin in use, usually called *rosin*, is obtained by distilling turpentine: the volatile oil passes over, and the resin remains in the still.

Among the resins are included: Copal, the product of *Rhus copallina*; Mastich, that of *Pistacia Lentiscus*; Coumia, that of *Icica Tacamahaca*; Carana, that of *Bursera acuminata*; and Elemi, that of *Amyris Plumieri*.

Resinite. [RETINITE.]

Resistance (Lat. resisto, *I withstand*). In Mechanics, this term denotes generally a force acting in opposition to another force, so as to destroy it or diminish its effect. Resistance is sometimes considered as of two kinds, active and passive; the active resistance being that which corresponds to the useful effect produced by a machine, and the passive that which belongs to the inertia of the machine. Thus, in raising water from a well, the active resistance to the force employed is measured by the quantity of water which is raised; and the passive resistance by the force required to overcome the weight of the bucket and the rope, the friction of the pulley on its axle, &c.

Resistance of Fluids. The force with which a solid body moving through a fluid is resisted or retarded. For many years the resistance experienced by a solid moving through a fluid, such as a ship sailing in the sea, was thought to be determinable only by certain recondite principles of hydrodynamics which theory could hardly reach; but it has of late been conclusively shown, that nearly nine-tenths of the resistance of well-formed ships is made up of friction. This doctrine, first propounded by Mr. Bourne in his *Treatise on the Screw Propeller*, and subsequently in his *Catechism of the Steam Engine*, published in 1856, has been further illustrated by Mr. Phipps, in a paper read before the Institution of Civil Engineers in 1865, and has been reduced to definite rules, of easy application, by Professor Rankine, in his *Treatise on Shipbuilding*, in course of publication in 1866. The subject was first pressed on Mr. Bourne's attention from having constructed ships on lines formed by allowing a pendulum, armed with a pencil, to vibrate in front of an endless web of paper, moving with a defined speed; since, as no power is lost by a pendulum beyond that which is lost by friction, Mr. Bourne concluded that a vessel formed on the principle that each particle of water shall be moved aside like a pendulum, slowly at first, and then faster, and by a reverse process shall finally come to rest at the stern, would be exempt from that large source of loss from the displacement of the water, which was then imputed to the progress of vessels of the ordinary character. It was found, however, on subjecting this hypothesis to the test of experiment, that although in the new class of vessels there was no wave raised at the bow, and no appearance anywhere of much resistance, the speed attained was little if at all superior to that of ordinary well-formed ships; and as in the new class of vessel the resistance was certainly, for the most part, produced by friction, the conclusion was reached that friction is the main cause of resistance in all vessels of moderately good form. Mr. Bourne accordingly proposed to estimate the resistance, not by the immersed midship section, as is the common method, but by the immersed perimeter, which would be an approximate measure of the resistance of all vessels of the same fineness and length. Nevertheless, as there was still a certain residuum of resistance depending upon the degree of sharpness of the vessel, or the difference in level between the bow and stern, Professor Rankine translated this resistance into surface friction also, by assuming as the rubbing surface of the vessel not the actual surface of the bottom but an *augmented* surface, which should be in all cases larger than the real surface, but larger in the proportion of the bluntness of the vessel, a common proportion of the augmented surface being 1·4 times that of the actual surface. In estimating the resistance of this augmented surface, the expression $f = \cdot 0036$, deduced by Professor Weisbach from experiments on the flow of water in iron pipes, was adopted as the coefficient of friction proper for the painted bottoms of iron vessels. The experiments, however, of M. Darcy, recently made in France, show that the friction of bare iron is one-half greater than if it is covered with a coat of smooth bitumen; and there can be no doubt that the condition of the surface of a ship's bottom will sensibly affect the speed attained. These topics are set forth at greater length than would be consistent with the limits of this article, in Mr. Bourne's *Hand-book of the Steam Engine*.

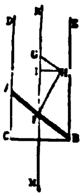
Sir Isaac Newton was the first who gave a general theory of the motions and actions of fluids; and it will be proper here to recapitulate the main doctrines of that theory, although, so far as regards its applicability to ships, it has now been superseded. [HYDRODYNAMICS.] The Newtonian theory of the resistance of fluids, which is given in the second book of the *Principia*, is founded on the assumption of the perfect intermobility of the particles of the fluid, and the equal propagation of pressure in all directions. These are, indeed, the characteristic properties of fluidity; nevertheless, the results of the mathematical theory differ so widely in many cases from actual experiment, that some philosophers have called into question the accuracy of the principles from which they are derived. The theory, however, notwithstanding its defects, furnishes some propositions of practical use. We shall, therefore, here give a general view of its leading principles.

It is evident that a solid body, in moving through a fluid, must communicate a motion to the fluid particles with which it successively comes in contact. Now, the quantity of motion communicated to the fluid is necessarily equal to that which is lost by the solid, and may therefore be taken as the measure of the resistance. From this it follows that the resistance upon a plane surface moved perpendicularly through a non-elastic fluid at rest, is proportional

to the density of the fluid, to the area of the plane, and to the square of the velocity.

On comparing this resistance with the force of gravity, we have the following theorem: *The direct resistance of an unelastic fluid on any plane surface is equal to the weight of a column of the fluid having the surface for its base, and for its altitude twice the height due to the velocity with which the surface moves through the fluid.*

The above measure of the force of resistance is deduced on the supposition that the direction of the motion is perpendicular to the plane. If the shock is received obliquely, the resistance will be greatly diminished.



Let AB represent the profile of the plane, and MN the direction of the motion of the plane in stagnant water, or of a vein of fluid DCBE striking against the plane, supposed to be fixed. Let F be the intersection of MN with AB, and draw BC perpendicular to MN. On FN take FG, to represent the resistance R, which AB would sustain if it were placed perpendicularly to MN, and were moving with the same velocity. This force FG may be resolved into two, FH perpendicular and HG parallel to AB, of which the latter produces no effect on the plane; hence the resistance is diminished, by reason of the oblique impact, in the ratio of FH : FG, or of sin i : 1 (i denoting the angle of incidence AFN). But, again, the absolute resistance is also proportional to the number of filaments which strike the plane; and it is obvious that the number which would strike it in the oblique position AB is less than the number which would strike it if directly opposed to the stream, in the ratio of BC : BA or of sin i : 1. Compounding this with the former ratio, the total diminution of resistance is as $\sin^2 i : 1$; i.e. the absolute resistance or pressure in the direction FH perpendicular to the plane is R $\sin^2 i$.

It still remains to find the effective impulse or resistance in the direction of the motion. Draw HI perpendicular to MM. The force in the direction FH may be resolved into FI and IH, of which the effective part is FI. Hence the effective impulse is to the absolute oblique impulse as FI to FH, or as sin i : 1; consequently the effective impulse on the plane in the direction MN is R $\sin^3 i$.

For other surfaces than planes, it is necessary to find an expression for the resistance on the differential element of the surface, which may be regarded as coinciding with its tangent plane; and the sum of all these resistances, found by the usual process of integration, will give the whole resistance on the surface.

Numerous experiments have been made for the purpose of ascertaining how far this theory of the resistance of fluids agrees with the actual facts, or for forming an empirical theory for the guidance of the engineer. Of the details of these experiments our limits will not permit us to give an account; but the principal experimenters, and works in which the results may be found, are the following: Sir Isaac Newton (*Principia*, lib. ii.); Mariotte (*Traité des Mouvemens des Eaux*); Gravesande (*System of Natural Philosophy*); D. Bernoulli and Krafft (*Comment. Petropol.*); Borda (*Mém. de l'Acad. des Sciences de Paris*, 1763 and 1767); Condorcet, D'Alembert, and Bossut, by order of the French government in 1775; Bossut (*Hydrodynamique*); Du Buat (*Principes d'Hydraulique*); Robins (*Gunnery*); Don George d'Ulloa (*Examen Maritimo*); Coulomb (*Mém. de l'Institut*, tom. iii.); Vince (*Phil. Trans.*); Hutton (*Tracts*); Beaufoy (*Nautical and Hydraulic Experiments*).

The quantity of fluid dragged along by a body moving in it has generally been considered to be independent of the velocity, and was estimated by Du Buat, from experiments made on spheres vibrating in water, to increase the quantity of displaced fluid in the ratio of 1 to 1·6. His experiments on prisms also showed that the quantity of dragged fluid was proportional to the bulk of the moving body. Mr. Baily (*Phil. Trans.* 1832) gives, as the mean results of his experiments on pendulums swinging in air, the ratio 1 to 1·846 as the increase of the displaced fluid from this cause; and remarks that the quantity appeared to depend on the form as well as magnitude of the moving body, but not on its weight or specific gravity. This circumstance, which considerably modifies the resistance, though made known by Du Buat in 1786, was overlooked by other experimenters, until rediscovered by Bessel in 1826, when engaged on experiments to determine the length of the seconds pendulum.

From the above considerations, it may be inferred that the resistance R opposed to any body moving through a fluid, considered as a pressure of so many pounds weight, will be expressed by an equation of this form,

$$R = (m + n)\,W A h;$$

where W is the weight in pounds of the unit of volume of the fluid (one cubic foot); A the area of the greatest transverse section of the body, expressed in square feet; h the height in feet due to the velocity, so that $h = v^2 \div 64$; and m and n numerical coefficients, constant for bodies of similar figure, but variable for bodies of different figures, and to be determined by experiment for each kind of body; m having reference to the impulse and pressure on the anterior surface, and n to the non-pressure on the posterior part. The following are a few of the cases for which values of m and n have been found.

When a thin plate is directly opposed to the impulse of a stream, the value of $m + n$ appears to increase with the area. If A is equal to a tenth of a square foot, $m + n = 1{\cdot}4$; and if A = 1 square foot, $m + n = 1{\cdot}9$. The value of $m + n$ for surfaces of larger dimensions has not been sufficiently determined. For a prismatic body terminated by two planes, the pressure

against the anterior force remains constant; but the non-pressure, or value of n, diminishes as the length increases. For a cube held fast in a stream, Du Buat found $m+n=1\cdot46$; and for a prism whose length was from three to six times the square root of its face, $m+n=1\cdot34$. But when the bodies moved in still water, he found, as for the thin plate, $m+n=1\cdot43$; for the cube, $m+n=1\cdot17$; and for the prism, $m+n=1\cdot10$.

By means of these values the actual resistances are readily computed for each body, when the velocity is given. Suppose the velocity to be 3 feet per second, and the opposing surface in each case to be 1 square foot. For $v=3$, we have $h=9+64=\cdot1406$. With respect to W, the weight of an imperial gallon of water, at temperature 62° and under the mean pressure, is 10 lbs. avoirdupois; but an imperial gallon contains 277·27 cubic inches, whence the weight of a cubic foot of water is 62·3 lbs. avoirdupois. Hence, if the bodies are impelled through stagnant water with a velocity of 3 feet per second, the absolute resistances in each case are as under:—

For the thin plate $R=1\cdot43\times62\cdot3\times\cdot1406=12\cdot5$ lbs.
For the cube $R=1\cdot17\times62\cdot3\times\cdot1406=10\cdot2$
For the prism $R=1\cdot10\times62\cdot3\times\cdot1406=\ 9\cdot6$

The effect produced by the addition of a poop or prow was also determined by Du Buat. The addition of a poop to a prismatic body whose length is four or five times its breadth only diminishes the resistance by a tenth part. But when a prow consisting of two equal vertical planes, making with each other an angle of 60°, was added, the resistance was reduced to about a half. On giving the prow the form of a semicylinder, the resistance was also reduced about a half. The section of the prow being a triangle whose height was double the base or breadth of the prism, the resistance was reduced to two-fifths. In general, a prow having a curved surface produces a greater diminution of the resistance than one of equal magnitude terminated by plane surfaces.

For a sphere moving in water or in air with a moderate velocity, the experiments give $m+n=0\cdot6$; but this value increases when the velocity becomes great, as in the case of a projectile. The experiments of Bossut on the model of a ship moved in the direction of its axis gave $m+n=0\cdot16$. This may be considered as the value corresponding to the solid of least resistance. For the effect with which solid bodies resist an effort tending to break or crush them, see STRENGTH OF MATERIALS; and for the resistance of the atmosphere on a projectile, see GUNNERY and PROJECTILE.

Resistance of Railway Trains. [RAILROADS.]

Resistance, Solid of Least. In Mechanics, the solid whose figure is such that in its motion through a fluid it sustains the least resistance of all others having the same length and base; or, on the other hand, being stationary in a current of fluid, offers the least interruption to the progress of that fluid. In the former case, it has been considered the best form for the stem of a ship; in the latter, the proper form for the pier of a bridge.

The law of resistance being known, the calculus enables us to determine the form of the solid of least resistance. Newton, in the thirty-fourth proposition of the second book of his *Principia*, has solved this problem on the hypothesis that the resistance is proportional to the square of the velocity.

Resistance of Steam Vessels. [STEAM NAVIGATION.]

Resolution (Lat. resolutio, from resolvo, *I unloose*). In Mathematics, this term is usually synonymous with *solution*. Thus the resolution of an equation is the procedure which leads ultimately to the discovery of its roots. [EQUATION.] The term is frequently used as the opposite of *composition*. Thus we speak of the resolution of a number into its prime factors, and of a force into its *components*. [COMPOSITION AND RESOLUTION OF FORCES.]

RESOLUTION. In Medicine and Surgery, this term implies the cessation or dispersion of inflammatory action without the formation of an abscess or mortification.

RESOLUTION. In Music, the writing out of a canon or fugue in partition from a single line.

RESOLUTION. In Parliamentary usage, 'every question, when agreed to, assumes the form either of an order or a resolution of the house. By its orders, the house directs its committees, its members, its officers, the order of its own proceedings, and the acts of all persons whom they may concern: by its resolutions, the house declares its own opinions and purposes.' (May, *Parliamentary Practice.*) [PARLIAMENT.]

Resolution of a Discord. In Music, the descent by a tone or a semitone, according as the mode may require, of a discord which has been heard in the preceding harmony.

Resolvent. In Algebra, an equation upon whose solution that of a given equation depends. [DIFFERENTIAL RESOLVENT.]

Resonance (Lat. resonantia, *a resounding*). In Music, a very indefinite term used in regard to the production or reverberation of sound.

Respiration (Lat. respiratio, from respiro, *I breathe*). The function by which the nutrient circulating fluid of an organised body is submitted to the influence of air, for the purpose of changing its properties. The great end which appears to be answered by respiration in animals is the removal of *carbonic acid* from venous blood. This gas is accordingly found in the air expired from the lungs; and the blood, having lost its carbonic acid, at the same time loses its dingy hue, and acquires the florid red which characterises arterial blood. The carbonic acid is attracted, as it were, out of the venous blood, by the oxygen of the air in the cellular structure of the lungs; while, at the same time, a portion of oxygen, about equal in bulk to that of the emitted carbonic acid, is absorbed by the blood, and contributes to its arterial character. The change from the arterial to the venous state, appears to take

place in the capillary junctions of the artery and vein; but how it is there effected we know not.

From the quantity of carbonic acid emitted from the lungs in a given time, it has been attempted to ascertain the quantity of carbon which is thrown off; but the usual estimates upon this subject, which place it at about 12 ounces in the 24 hours, are probably overrated, inasmuch as that quantity of carbon is more than that which exists in the food daily taken into the stomach. If we average it at 6 to 7 ounces, it will probably be nearer the truth. Besides carbonic acid, there is also a quantity of aqueous vapour thrown out with the expired air; this is probably produced chiefly by the superficial exhalants of the lungs, but it may also be partly derived from transpiration from the blood. It has not been satisfactorily ascertained whether the nitrogen of the air is affected by respiration. The most recent experiments would, however, seem to show that during fasting nitrogen is absorbed.

Respiration of Plants. [BOTANY.]

Respirator. An instrument fitted to cover the mouth, over which it is retained by proper bandages; it is constructed of a series of flattened silver or gilt wires, over and between which the air passes and repasses in the act of respiration and of speaking. It is presumed that the warm air emitted from the lungs imparts its excess of temperature to the small metallic bars, and that these in their turn impart heat to the cold air drawn through them at each inspiration; so that in this way the low temperature of the external air in cold weather is mitigated before it reaches the lungs, and its supposed noxious influence is prevented. When a handkerchief is tied over the mouth, and we are obliged to breathe through the nose, the extreme low temperature of the external air is similarly mitigated before it reaches the lungs.

Respite. In Law, a suspension, delay, or forbearance: as of the execution of a criminal sentence.

Respond (Lat. respondeo, *I answer*). A half pillar, or pier, introduced in a wall to support an arch; it constitutes, in fact, a continuation of the line of the arch in the horizontal part of the wall, and appears to be introduced for the purpose of supporting it.

Respondentia (Lat. respondeo, *I promise in return*). In Mercantile Law, a species of mortgage in the nature of bottomry, but differing from it in that the loan is effected on the security of the freight, and not on that of the ship itself. [BOTTOMRY.]

Responsible Government. In Politics, this term, although rather indefinite in point of phraseology, has acquired by usage a special meaning. All executive authorities, except the sovereign himself in a pure monarchy, are in truth *responsible* to some power or other for abuse of their functions; but under the British constitution, the ministry, together with its head, the prime minister, are in a peculiar sense *responsible* to parliament, i.e. it is the established usage that on a vote equivalent to *want of confidence* they should resign their offices, and make way for an administration more in harmony with the sentiments of the legislature. This system has been of late carried into practice in the larger British colonies, where the governor, appointed by the crown, is assisted by a ministry, appointed indeed by himself, but *responsible*, in the sense above indicated, to the colonial legislature. This system is, in common language, contrasted with that which prevails in other constitutional countries, and particularly the United States, where the president, elected for a term of four years, appoints a ministry dependent on himself, and not subject to change according to the votes of the legislature.

Rest (A.-Sax. ræst, Gr. rast). In Music, a pause or interval of time, during which there is an intermission of the voice or sound.

REST. [RESERVE.]

Restiaceæ (Restia, one of the genera). A natural order of Glumal Endogens, of little interest except to botanists. They occur chiefly in the woods and marshes of South America, New Holland, and Southern Africa, and are herbs or undershrubs, of a rush-like aspect.

Restiform (Lat. restis, *a rope*, and forma). In Anatomy, this term is applied to certain rope-like columns or tracts, behind the *lateral tracts* of the medulla oblongata. The *restiform tract* is continuous below with the posterior columns of the myelon; while above, its fibres may be traced transversely through the pons into the cerebellum. If the restiform tracts be irritated, the most acute suffering is produced.

Restitution of Conjugal Rights. In Law, the denomination of a suit between husband and wife, brought in the Court of Divorce and Matrimonial Causes, for the purpose of compelling cohabitation, if refused by either party.

Restitution, Writ of. In Law, a writ of restitution lies where judgment has been reversed, to restore to the defendant what he has lost by the effect of the erroneous judgment. Restitution of goods to a party robbed was unknown to the common law until the stat. 21 Hen. VIII. c. 11. By the statute 24 & 25 Vict. c. 96, it is now in the power of the court to award a writ of restitution of goods and chattels, or to restore them in a summary manner, where a thief or fraudulent taker has been indicted on the part of the owner and convicted. Such restitution cannot be granted of a valuable security, where the property has passed into other hands by a bonâ fide transaction. But a writ of restitution will reach goods stolen, although they have been sold in market overt. Restitution can be had only from the person in possession of the goods at the time of and after the felon's conviction.

Restoration, The. In English History, this name is applied by way of eminence to the restoration of Charles II. to the throne after an interregnum of eleven years and four months, from Jan. 30, 1649, when Charles I. was beheaded, till May 29, 1660.

Restriction of Cash Payments. Between February 27, 1797, and February 1, 1820, the Bank of England was permitted to issue notes for which the holder could not demand gold in exchange. This regulation is an important epoch in the history of banking. For the facts of the restriction and the resumption, see Tooke's *History of Prices*, especially vol. iv.

Resultant (Lat. resulto, *I rebound*). In Mechanics, the term *resultant* is applied to a *force*, *motion*, *velocity* or *rotation* which is mechanically equivalent to several other forces, motions, velocities or rotations. [COMPOSITION AND RESOLUTION OF FORCES AND ROTATIONS.]

In the *higher algebra*, the *resultant* of a system of homogeneous equations, involving as many variables as there are equations, is an important function of the coefficients which, equated to zero, expresses the condition of the existence of a common set of roots, and consequently the result of the elimination of all the variables. The synonymous term *eliminant*, now rarely used, was suggested by the latter property. The resultant is frequently considered apart from the system of equations, and is then referred to as the *resultant of a system of quantics*.

In the case of two binary quantics of the m^{th} and n^{th} degrees, respectively written thus,

$$\phi = a_0 x^m + a_1 x^{m-1} y + \ldots a_m y^m$$
$$= (a_0, a_1 \ldots a_m \between x, y)^m,$$
$$\psi = b_0 x^n + b_1 x^{n-1} y + \ldots b_n y^n$$
$$= (b_0, b_1 \ldots b_n \between x, y)^n$$

[QUANTICS], so that the coefficient in every term has a suffix equal to the exponent of the power of one of the facients y in that term, the resultant is a homogeneous function of the coefficients of each quantic of a degree equal to the order of the other quantic. In the above case, therefore, the resultant is of the n^{th} order in the coefficients a, and of the m^{th} in the coefficients b. Moreover, the sum of the suffixes in each term of the resultant is always constant, and equal to the product mn of the orders of the quantics. This constant sum is called the *weight* of the resultant. [WEIGHT OF A FUNCTION.] Thus the resultant of the two binary quadrics

$$(a_0, a_1, a_2 \between x, y)^2, (b_0, b_1, b_2 \between x, y)^2$$

is $(a_0 b_2 - a_2 b_0)^2 + (a_1 b_0 - a_0 b_1)(a_1 b_2 - a_2 b_1)$ which is of the 2nd order in each of the coefficients a and b, and whose weight is 4.

In general the resultant of any number of quantics of different orders is a homogeneous function of the coefficients of each, of a degree equal to the product of the orders of all the remaining quantics, and if the coefficients in the several quantics be affected with suffixes respectively equal to the exponents of the powers of some one of the facients which those coefficients multiply, the sum of the suffixes in every term of the resultant will be equal to the product of the orders of the quantics.

The well-known and important fact that a system of n homogeneous equations of the orders $m_1, m_2 \ldots m_n$, respectively, in $n+1$ variables can be satisfied, simultaneously, by $m_1 m_2 \ldots m_n$ systems of values of these variables, is an immediate consequence of the above properties of the resultant.

The resultant of a system of quantics can often be expressed as a determinant. [ELIMINATION.] For instance, the resultant of a system of n linear and homogeneous equations in n variables is the determinant of the n^{th} order whose constituents, in any column, are the several coefficients of one of the variables. Again, the resultant of the above two binary quadrics is the determinant

$$\begin{vmatrix} a_0, & a_1, & a_2, & 0 \\ 0, & a_0, & a_1, & a_2 \\ b_0, & b_1, & b_2, & 0 \\ 0, & b_0, & b_1, & b_2 \end{vmatrix}$$

When the given quantics are the several first derived functions of one and the same quantic, the resultant is called the *discriminant* of that quantic. [DISCRIMINANT.]

Resulting Trust. In Law, a species of trust arising by operation of law. If a purchaser of property takes a conveyance in the name of another person, then if there is nothing to indicate an intention of conferring a beneficial interest on such person, the trust or benefit of the property conveyed is said to result to the purchaser who paid for it. Again, if a settlement of property is made, and no trusts of it are declared, or if the trusts declared are not such as to exhaust the beneficial interest in the property, there is said to be a resulting trust to the settlor of the beneficial interest undisposed of.

Resulting Use. In Law, a species of use arising by operation of law. Where on a conveyance of the legal estate or seisin in lands no uses of it are declared, or if the uses declared are not sufficient to exhaust the whole fee simple, the use remaining undisposed of is said to result to the original owner. [RESULTING TRUST; USE.]

Resumption of Cash Payments. During the great continental war, and for four years after the battle of Waterloo, the Bank of England was empowered to issue inconvertible notes. For some portion of this time these notes were at a discount, the discount being greatest between 1810 and 1816. At the beginning of the year 1817, the directors of the Bank prepared to resume cash payments, but the negotiation of considerable loans on the part of France, Austria, and Russia, again affected the note circulation, and the natural process of resumption was checked for a time. It was resolved, however, that committees of both Houses of Parliament should report on the currency, and in consequence the Act of 1819, the first of Peel's Currency Acts, was passed. This Act provided that the Bank should exchange its notes for gold, such gold to be in ingots, and in quantities of not less than 60 ounces, first, from February 1 to October 1,

1820, at the rate of 4*l.* 1*s.* the oz.; next, from October 1, 1820, to May 1, 1821, at the rate of 3*l.* 19*s.* 6*d.*; lastly, between May 1, 1821, and May 1, 1823, at 3*l.* 17*s.* 10½*d.* After that date notes of all denominations and in all quantities were to be convertible on demand.

Resupinate (Lat. resupinatus, *lying on the back*). In Botany, a term applied to parts which become inverted, usually by the twisting of their stalk. It occurs in the case of many orchidaceous flowers, and the leaves of *Alströmeria*.

Resurrection. In Theology, this term is especially applied to the rising again of Christ from the dead, as narrated in the Gospels and the Acts of the Apostles.

Resuscitation (Lat. resuscitatio). This term is generally used to signify the restoring to animation of persons apparently dead. The first and principal object in these cases is to aërate the blood by the artificial introduction of fresh air into the lungs, and to restore the natural function of respiration. The lungs, therefore, must be inflated, and proper stimulants applied when necessary; among these, in cases of drowning and of apparent death from exposure to cold, friction is eminently important: after hanging, the vessels of the brain often require to be unloaded by venesection in the jugular vein. Galvanism is sometimes resorted to, but generally without effect. In all these cases no time should be lost, as everything depends upon *prompt* treatment, as well as upon *proper* means; and many lives have been lost for want of immediate aid, and skill in applying it. The attempts to restore suspended animation should not be given up till unequivocal proofs of death are manifest. The details of the management of different cases of apparent death are too extensive to come within our limits: upon this subject the reader may advantageously consult Taylor's *Medical Jurisprudence*. [DROWNING.]

Retainer (Lat. retineo, *I keep back*). In old English Law, a servant not dwelling in the master's house or employed by him in any distinct occupation, but wearing his *livery* (i.e. hat, badge, or suit), and attending on particular occasions: an important relic of the times of private warfare. The giving liveries, or *retaining* this class of servants, was forbidden by many statutes with little effect. The statutes themselves were repealed by 3 Ch. I. c. 1; but the usage had nearly ceased.

Retainer or **Retaining Fee.** In the language of the Bar, a fee given to a counsel to secure his services; or rather, as it has been said, to prevent the opposite side from engaging them. A *special* retainer is for a particular case expected to come on. A *general* retainer is given by a party desirous of securing a priority of claim on the counsel's services for any case which he may have in any court which that counsel attends. The effect of it is merely this, that if a counsel having a general retainer receive a special retainer on the other side, he cannot accept it until twenty-four hours after notice shall have been given of its arrival to the party so generally retaining him; when, if he does not receive a brief or a special retainer from the latter, he is bound to accept it. The same word in its strict legal acceptation signifies the engagement of an attorney by his client.

Retaining Wall. A wall built for the purpose of resisting the thrust of the ground at the back, or for confining a body of water in a reservoir. The principles to be observed in proportioning the thickness of these structures to their height, involve the most difficult problems with which the civil engineer has to deal. The foundations of retaining walls must be such that they shall not be liable to displacement laterally under the influence of the pressure behind them, nor vertically under the perpendicular weight brought upon them. According to circumstances, then, the foundations of a retaining wall may be carried down to the solid ground, they may be executed on piles, or they may be entirely of concrete. Local considerations of economy will, generally speaking, regulate the manner in which this part of a work will be executed; the only conditions which must be observed are that the sum of the forces tending to displace the wall shall be exceeded by the force tending to produce stability. The thickness to be given to the upper part of a retaining wall will very much depend on the nature of the material to be supported, and on the weight to be sustained; the thickness of such walls will have to be varied also in proportion to the length in which they may have to resist the weight brought upon them without any intermediate support. As a general rule, the thickness of retaining walls is made one-third of the height of the bank which they are intended to support, being diminished by sets-off on the inside, so as to preserve the perpendicularity of the external face; but the thickness of retaining walls destined to support the banks of rivers, or quays, is generally made about equal to one-half their height above the footings, on the average, in order to resist the action of the water upon the materials of the earthwork behind them. Of course, there are modifications of form, and dispositions of material in retaining walls, that may allow the thickness above given to be much reduced; as, for instance, the face of the walls may be made curvilinear in vertical section, or it may be made with counter forts, and circular parts like inverts, between: but the rules above given will generally apply, and the means adopted for saving masonry will demand superior execution or extraordinary care. For further details the reader is referred to Moseley's *Engineering and Architecture*; Murray, *On Retaining Walls*; Poncelet, *Sur les Revêtements*; Mayniel, *Sur la Poussée des Terres*; De Prony, *Nouvelle Architecture Hydraulique*; Navier, *Résumé des Leçons données à l'École des Ponts et Chaussées*; &c. But the indications given in all these cases must be received with a considerable amount of reserve, inasmuch as the earthwork at the back of the walls erected

to support them may become, when exposed to the tidal waters, loaded with a semi-fluid denser than water, which would greatly modify its action upon the walls. Hence the great thickness of the retaining walls of canals, reservoirs, sea walls, docks, &c. Much of the necessary thickness will depend upon the nature of the soil.

Retama (Arab. Ræetem). A genus of *Leguminosæ* closely allied to our Broom (*Sarothamnus*), and consisting of elegant shrubs, distributed over the Mediterranean region and the Canary Isles. Ræetem is the name given by the Arabs to a white-flowered species, *R. Rætam*, which grows in Arabia and Syria. According to Forskål, an infusion of its bitter roots is drunk by the Arabs for internal pains, and the shoots macerated in water are applied to wounds. The Arabic name Ræetem, altered slightly into *Retama*, is the common appellation of the plants of this genus in Spain. One of the species is of great utility in staying the sand along the shores of Spain, converting the most barren spots into odoriferous gardens. The young shoots are eagerly eaten by goats, and the twigs are used for tying bundles.

Retardation (Lat. retardatio, from tardus, *slow*). The act of hindering the free progress of a body, and ultimately, therefore, stopping it. It arises from the opposition of the medium *in* which the body moves, or from the friction of the surface *upon* which it moves. [FRICTION; RESISTANCE.]

RETARDATION. In Gunnery, the loss of velocity of a projectile, in consequence of the air's resistance. [GUNNERY.]

Rete Mucosum (Lat.). The soft matter, or layer, situated between the cuticle and the cutis; it is the seat of the colour of the skin. It is black in the negro, and the colouring matter is of such a nature as to admit of being bleached by the action of chlorine.

Retia Mirabilia (Lat. *wonderful nets*). The vaso-ganglionic structures, or network of blood-vessels, at the base and in other parts of the brain in vertebrata.

Retiaries (Lat. retiarius, from rete, *a net*). In Entomology, those spiders are so called which spin a web or net to entrap their prey.

Retiarii (Lat. from rete). The name of a class of Roman gladiators. The retiarius was furnished with a trident and net, with no more covering than a short tunic; and with these implements he endeavoured to entangle and despatch his adversary, who was called *secutor* (from sequi, *to follow*) and was armed with a helmet, a shield, and sword. [GLADIATORS.]

Reticulate (Lat. reticulatus, from rete). In Botany, formed like network. The term is especially employed to describe the condition of the venation in Exogens, as compared with that of Endogens.

RETICULATE. In Zoology, when a surface has a number of minute impressed lines which intersect each other in various directions, like the meshes of a net.

Reticulated Work. In Architecture, a method of executing masonry in which the stones are square and laid lozenge-wise, resembling the meshes of a net. This species of masonry is scarcely ever practised in the present day; but it was very common amongst the ancients.

Reticulates. The name of a section of Lithophytes, comprehending those in which the polype cells have a reticulate disposition on the surface of expanded plates.

Reticule (Lat. reticulum). In a telescope, a network of fine spider's webs or wires crossing each other at right angles, and dividing the field of view into a series of small equal squares. It has been long used for observations on the quantity of the enlightened parts of a luminary during eclipses; and is found well adapted for that and similar purposes.

Reticulum (Lat. dim. of rete). The name of the *honeycomb bag*, or second cavity of the complex stomach of the Ruminant quadrupeds; so called from the reticulate or honeycomb-like disposition of the cells, mostly hexagonal, which occupy its inner surface.

RETICULUM. In Botany, the débris of interlacing fibres found at the base of the petiole in palm-trees.

Retina. The pulpy expansion of the optic nerve in the interior of the eye; it is the seat of vision.

Retinaculum (Lat. *a hold-fast*). In Botany, the name of a hispid gland found on the stigmas of orchids and asclepiads, by which the pollen masses are held fast.

Retinalite (Gr. ῥητίνη, *resin*, and λίθος, *stone*). A massive variety of Serpentine with a resinous appearance, from Canada.

Retinite (Gr. ῥητίνη). A mineral substance, intermediate between resin and asphalt, discovered by Mr. Hatchett in roundish or irregular opaque lumps of a yellowish or pale brownish-yellow colour, in tertiary clay at Bovey Tracey, in Devonshire, associated with lignite; also at Halle, and in peat at Osnabrück in Hanover. When digested in alcohol, it yields a portion of resin, and asphalt remains.

Retinitis. Inflammation of the retina.

Retipeds (Lat. rete, and pes, *a foot*). The name given by Scopoli to one of the divisions of a binary arrangement of birds, including all those which have the skin of the tarsi divided into small polygonal scales.

Retired Flank. In Military art, a flank bent inwards towards the rear of the work or army, of which it forms a part.

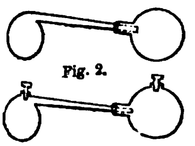
Retorsion (Lat. retorqueo, *I drive back*). In International Law, a designation for the use, by a power injured through the withdrawal by another power of the indulgences sanctioned by *comity of nations* in its favour, of the power of *retorting* by the withdrawal of the like indulgences from the latter. [COMITY.]

Retort (Lat. retortus, part. of retorqueo). A Chemical vessel employed in a variety of distillations. It is generally made of glass or earthenware, and sometimes is provided with a stopper so placed above the bulb as to enable

substances to be introduced into it without soiling the neck; in this case it is called a *tubulated* retort. A *receiver* is usually annexed to it for the purpose of collecting the products of distillation. Fig. 1 represents a plain retort and receiver; in fig. 2 both are tubulated. Retorts of large size, made of iron or of fire-clay, are used for the distillation of coal in the manufacture of gas.

Fig. 1.

Fig. 2.



Retreat (Fr. retraite). The name given to the beating of drums or sound of trumpets at sunset in all garrisons; after which sentries challenge, and no trumpet sounds or drum beats, except for watch-setting and tattoo, or in case of an alarm, until the following Reveille.

Retrenchment (Fr. retranchement). In Fortification, a line of works formed so as to cut off parts of a fortress, and enable the garrison to continue the defence after the parts outside of them are taken. [Fortification.]

Retrocedent (Lat. retrocedo, *I go back*). In Pathology, a term applied to those diseases which move about from one part of the body to another; as *retrocedent gout*, when it leaves the toe for the stomach.

Retrogradation. A term applied to the apparent motion of a planet when it is contrary to the order of the signs, or when the planet appears to move westward among the fixed stars. [Planet.]

Retrograde (Lat. retrogradis, *going backward*). This term is applied to backward as opposed to direct motion. In Astronomy, the apparent motion, from east to west, of the heavens is retrograde.

Retti Weights. The small egg-shaped scarlet and black seeds of *Abrus precatorius*, which are employed in India as weights.

Return. In Architecture, a projection, moulding, or wall continued in a different or an opposite direction to that of the original direction of the body returned.

Return. In Law, in its most usual signification, this word is applied to writs. The return to a writ is, properly speaking, a recital by the sheriff or other officer to whom it was directed of what he has done in execution of it, as, for example, in cases of civil process, that the defendant cannot be found (technically called *non est inventus*), has no goods within the sheriff's bailiwick (nulla bona), and so forth. This is indorsed on the writ; and the writ is then delivered into the court whence it issued on the *return day* or day when the writ is returnable. The remedy against the sheriff for a false return is by action on the case. The return of members of parliament is thus, strictly speaking, the return by the sheriff, or other returning officer, of the writ addressed to him, certifying the election in pursuance of it. [Parliament.]

Retuse (Lat. retusus, *blunted*). In Botany, a term applied to parts which terminate in a round end depressed in the centre.

Retzite. A red variety of Zeolite from Ædelfors in Sweden; named after Retzius, by whom it was analysed.

Reussin or **Reussite.** Anhydrous sulphate of soda and magnesia, occurring in crystals and in mealy efflorescences, near Seidlitz in Bohemia. Named after Reuss, the Austrian mineralogist.

Revalenta Arabica. The commercial name (formed by transposition from the name of the plant which yields it) for a much vaunted kind of meal, which is simply the prepared seeds of the Lentil, *Ervum Lens*. It is sometimes called Ervalenta, which comes nearer its true name.

Reveille (Fr. réveil, *an awaking*). The name given to the beating of drums or sound of trumpets at daybreak in all garrisons, after which sentries do not challenge till the following Retreat.

Revelation. [Theology.]

Revelation, Book of. [Apocalypse.]

Revels, Master of the, or **Lord of Misrule.** The name of an officer formerly attached pro tempore to royal and other distinguished houses, whose duty it was to preside over the Christmas entertainments. This office was first permanently instituted in the reign of Henry VIII.; it appears to have gone out of fashion towards the end of the seventeenth century.

Revendication (Fr.). A term of the Civil Law, signifying a claim legally made to recover property, by one claiming as owner. The right of property must, generally speaking, be complete, to proceed to the action of revendication; thus, no such action can be brought for corporeal things until after delivery, by which they pass.

Revenue (Fr. revenu). The name given to the income of a state derived from the customs, excise, taxation, and other sources, and appropriated to the payment of the national expenses. Useful and comprehensive tables, showing the revenue and expenditure of Great Britain, will be found in the parliamentary papers printed every session.

Reverberatory Furnace. A furnace in which the flame is made to pass over a bridge, and then beat down again upon a hearth or surface, on which the materials to be heated are placed. [Founding.]

Reverend (Lat. reverendus). A title of respect given to the clergy. In Roman Catholic countries the members of the different religious orders are styled *reverend*. In England deans are *very reverend*, bishops *right reverend*, and archbishops *most reverend*. In Scotland, the principals of the universities and the moderator of the General Assembly for the time being are styled *very reverend*.

Reverse (Lat. reversus, part. of reverto, *I turn back*). In Numismatics, the opposite to the obverse or face of the coin or medal. [Numismatics; Obverse.]

Reversed Dip. In mountain districts, as in the Alps, where the strata frequently show proof of having been lifted up by a force acting intensely, but with limited play, they have sometimes been lifted through an angle greater than a right angle. The result is that beds originally uppermost are now apparently underlying, and this phenomenon is expressed by the term *reversed dip.* Except in districts where there have been extensive movements, it is not likely that this condition of the beds can exist; but wherever it does occur, it is extremely puzzling to the young geologist.

Besides the cases in the Alps and other mountain tracts, there are not wanting folded strata, chiefly in the coal measures, where a reversion of dip is repeated over and over again. Such cases are common both in the French and Belgian coal-fields, and are the result of lateral pressure. Reversed dip has been noticed in some parts of England, though rarely. Beds thus displaced, if followed along their line of outcrop, are soon found to have their proper relative position.

Reversion. In Law, a reversion is defined to be the residue of an estate in lands, tenements, or hereditaments, left in the grantor, to commence in possession after the determination of some particular estate granted by him. Thus, for example, when a landlord grants a lease for years, the estate remaining in him is called the *reversion*, and carries the right to the rent reserved, although the tenant enjoys the actual posession of the land during his tenancy.

Reversion, Reversionary Payments. In the doctrine of Annuities, a reversion is a payment which is not to be received, or a benefit which does not begin, until the happening of some event, as the death of a person now living. Payments which are to be received at the end of a specified period of time are usually called *deferred payments.*

The present value of a sum of money to be received on the death of an individual of a given age depends evidently upon the chances which the individual has of surviving each future year of age, combined with the interest of money. The method by which the value is calculated, from an observed or assumed law of mortality, has been explained under the term ASSURANCE; and for the sake of facilitating calculations of this kind, which are of very frequent occurrence in the affairs of life, extensive tables have been published, computed from various hypotheses of mortality, and at different rates of interest. Such tables are usually exhibited in the form of Annuity Tables, from which the solution of all questions relating to assurance and reversions is easily deduced. [ANNUITY; ASSURANCE.]

Let A denote the value of an annuity of 1*l.* on a life of a given age, V the present value of 1*l.* to be received at the end of the year in which the life fails (the year being supposed to commence with the day on which the annuity is payable), r the rate of interest, and $v = 1 \div (1+r)$; then

$$V = v(1+A) - A, \text{ or } V = v - (1-v)A.$$

Suppose, for example, that on the death of *A.*, whose present age is fifty-five, the sum of 5,000*l.* is to revert to *B.*, or his assigns, and that *B.* proposes to sell his interest in this reversion; and let it be proposed to calculate the sum which he ought now to receive, allowing the purchaser interest at the rate of 4 per cent. per annum. In the table given under the term ANNUITY the value of an annuity of 1*l.* on a male life aged fifty-five is 11·0392. At 4 per cent. we have $r = \cdot 04$, and $v = 1 \div 1\cdot 04$; therefore $V = \frac{12\cdot 0392}{1\cdot 04} - 11\cdot 0392 = \cdot 5370$. This is the value of the reversion of 1*l.*; consequently 5,000*l.* × ·5370 = 2,685*l.* is the sum which *B.* should receive for his reversionary interest.

When the reversionary benefit consists of an annuity to commence upon the death of an individual, and to continue for a term of years certain, its value is found by computing the value of the annuity for the assigned period, and proceeding as in the above example; but when it consists of an annuity commencing upon the death of one individual, and terminable upon the death of another, it becomes necessary to have recourse to tables of annuities on joint lives. Thus, if *A.* becomes entitled upon the death of *B.* to an annuity of 1*l.* for the remainder of his life, the present value of the reversion, or of *A.*'s interest, is equal to B − A B; where B denotes the present value of the annuity on the life of *B.*, and A B the value of the annuity on the joint lives of *A.* and *B.*, that is to continue only so long as both remain alive.

The four following rules give the solution of all the cases of reversionary annuities which can arise when three lives are concerned, and it is seldom that a case occurs in practice involving a greater number. It is to be observed that the two letters A B standing together denote, as above, the value of an annuity on the joint lives of *A.* and *B.*, B P that of an annuity on the joint lives of *B.* and *P.*, A P Q that of an annuity on the joint continuance of the three lives *A.*, *P.*, *Q.*, and so on. Let R be the value of the reversionary annuity in each case.

1. On a single life *A.*, after the longest of two lives *P.* and *Q.*; R = A − A P − A Q + A P Q.
2. On the longest of two lives *A.*, *B.*, after a single life *P.*; R = A + B − A B − A P − B P + A P B.
3. On a single life *A.*, after two joint lives *P.*, *Q.*; R = A − A P Q.
4. On two joint lives *A.*, *B.*, after a single life *P.*; R = A B − A B P.

When reversionary benefits are contingent on lives failing in an assigned order, as for instance an annuity to be received upon the death of *A.* provided he die while *B.* is living, the formula becomes more intricate, and could scarcely be explained without entering into details inconsistent with the nature of this work. For full information on the subject, see the Treatises of Baily (1813) and Milne (1816). We may remark, however, that the formulæ for the so-

lutions of questions connected with this subject may be greatly simplified by the use of an appropriate notation: for examples of which, see the 'Essay on Probabilities' in the *Cabinet Cyclopædia*; and Hardy's *New and General Notation for Life Contingencies* (1840); in which last work the solutions of all the cases of annuities and assurances which can arise, when not more than three lives are concerned, are arranged in a convenient table.

Reversion of Series. In Algebra, a method of expressing the value of an unknown quantity which is involved in an infinite series of terms, by means of another series of terms, involving the powers of the quantity to which the proposed series is equal. Thus if the proposed series be

$$z = ax + bx^2 + cx^3 + dx^4 + \ldots \text{ad inf.} \ldots (1)$$

and if we assume

$$x = Az + Bz^2 + Cz^3 + Dz^4 + \ldots \text{ad inf.} \ldots (2)$$

the original series will be reverted on determining the coefficients A, B, C, D, &c.

The ordinary method consists in substituting the last series (2) and its powers for x and its powers in the series (1), and equating the coefficients of like powers of z in order to obtain the values of A, B, C, &c. Maclaurin's *Theorem* may be employed advantageously for the same purpose. Arbogast, in his *Calcul des Dérivations*, gives a general formula whereby these coefficients can be calculated with comparatively little trouble. In the *Penny Cyclopædia* the values of eleven of these coefficients and the law of their formation are given.

Revetment (Fr. revêtement). In Fortification, a facing to the steep sides of a ditch or parapet. In field works it may be of timber, turf, hurdles, gabions, &c.; in permanent works it is generally of masonry. In permanent fortification, when a portion only of the exterior of the rampart is revetted, the wall is called a *demi-revetment*. When the wall is carried up to the superior slope, it is called a *full revetment*; the latter is much more defensible against escalade.

Revetments have been constructed in four different forms, named from their profiles, *rectangular*, *leaning*, *sloping*, and *counter-sloping*. The first of these is a wall of equal thickness throughout; the second differs only in being inclined to the bank supported, so as more effectually to resist the pressure of the earth; the third has a greater thickness at the base than the top, its back being vertical, and its face sloping; the fourth has its back sloping, and face vertical. *Hollow* or *counterarched revetments* are those constructed with counter-arches, forming vaulted defensive galleries, or filled in with earth.

Review (Fr. revue). The name now commonly assumed, by literary usage, for periodical publications consisting of a collection of critical essays. The *Journal des Savans*, commenced at Paris in 1665 by M. de Sallo, is commonly cited as the first review properly so called. The most distinguished modern journals under the name of review in France are, the *Revue Encyclopédique*, the oldest of them (now extinct); the *Revue Française* and *Revue des Deux Mondes*; and the *Revue Britannique*, which consists of translations from the English. In England the *Monthly Review* (established in 1749) was the first publication of its kind. The establishment of the *Edinburgh Review* in 1802, followed by that of the *Quarterly* in 1809, may be said to have commenced a new era in criticism: from that time reviews have been adopted as the organs for conveying the opinions of sects and parties in religion and politics, as well as in literature. All the leading works of this description (the *Edinburgh*, *Quarterly*, *Westminster*, *British Quarterly*, *North British*, *Church of England*, *Christian Remembrancer*, and *Dublin*) now appear quarterly, or nearly so. The management of reviews in England is in the hands of an editor, whose name, however, does not appear, the publisher being the party responsible. The articles are generally anonymous. All these reviews adhere to their designation, the articles admitted being in the form of *reviews* on some work or works specified at the head, although, in point of fact, the latter are often not even noticed by the reviewer, his remarks being more in the form of a general essay than of a review. In this way they serve the purpose of affording governments or political parties the means of making statements of facts, or declarations of opinion, which do not involve them in the difficulties of direct responsibility, and yet are generally understood to convey their sentiments. The pay of writers in reviews is various, depending not only on the means of the review, but on the rules adopted by particular editors; for some have thought proper to equalise their rate of remuneration, others to retain in their own hands the power of estimating contributions according to their supposed value. The French *revues* are conducted on a different plan. Articles in general have the name of the contributor attached; and the form of a *review* is not preserved, tales, poetry, essays on the politics of the day, &c. being admitted indiscriminately. This plan has been adopted in some of the reviews recently issued in this country, as in the *Fortnightly Review*, *Macmillan's Magazine*, the *Contemporary Review*, &c. Besides France and England, reviews have been long established in the other European states, and in America; but this species of publication has taken the deepest root in Germany, where reviews may be said, without exaggeration, to appear daily, though none of them possess the influence of the leading English reviews. (Hallam, *Literary History*, pt. iv. ch. vii.)

Review. In Military language, an inspection of a body of troops assembled for that purpose by a royal personage or officer of high rank.

Review. In a Naval sense, a fleet or squadron passing through various manœuvres and evolutions, with perhaps a pretended battle.

Review, Bill of. In Law, a bill filed in order to procure an examination and alteration

of a final decree in Chancery duly signed and enrolled. If not enrolled, a petition of rehearing is the proper proceeding.

Review, Court of. A court of appeal from the Commissioners in Bankruptcy, established by stat. 1 and 2 Wm. IV. c. 56, and abolished by 10 and 11 Vict. c. 102.

Revise (Lat. revideo, *I see again*). In Printing, a second proof taken for examination by the first proof. A *press revise* is the final proof pulled before printing off the form of types.

Revivor, Bill of. In Law, a continuance of an original bill in a court of equity, when by death some party to it has become incapable of prosecuting or defending a suit, or a female plaintiff has incapacitated herself by marriage from suing alone. A bill *of revivor and supplement* continues a suit upon an abatement, and supplies defects which may have arisen from some event subsequent to the institution of the suit. In many cases an order of revivor may now be obtained without a fresh bill.

Revocation, Power of. In Law, a power contained in a deed, by which the grantor retains the liberty to revoke it. Wills are in their nature revocable, but deeds as a rule cannot be revoked unless power for that purpose is reserved.

Revolute (Lat. revolutus, part. of revolvo, *I roll back*). In Botany or Zoology, when a part is rolled outwards or backwards.

Revolution (Lat. revolutio). In Astronomy, this word is used to signify the motion of a secondary body round a primary one, as contradistinguished from *rotation*, which signifies motion round an axis. The *time of revolution* is the period in which a planet, satellite, or comet returns to the place in its orbit from which we estimate its setting out.

Revolution. In Mechanics, this term is synonymous with *rotation*.

Revolution, French (Era of the). In Chronology, this era was substituted for the Christian era in all public acts and documents, by a decree of the National Convention in 1793; and fixed at the 22nd of September, 1792, the day of the foundation of the French republic. It was abolished by Napoleon, and the Christian era restored in 1806.

Revolution, Surface of. In Geometry, a surface generated by the motion of a line, right or curved, around a fixed axis. Thus the surface generated by the motion of one right line around another is either a *cone* or a *hyperboloid of revolution* according as the two lines do or do not intersect each other. The motion of an ellipse around one of its axes generates an *ellipsoid of revolution*, which receives the name of *prolate* or *oblate spheroid* according as the major or minor axis remains fixed.

It is obvious that every sphere whose centre is in the axis must intersect the surface of revolution in circles whose planes are perpendicular to the fixed axis; so that the general equation of a surface of revolution is

$$(x-a)^2+(y-b)^2+(z-c)^2=F\,(lx+my+nz),$$

where a, b, c are the coordinates of any point in the axis; l, m, n are proportional to the direction-cosines of the latter, and F any functional symbol. The lines of curvature on a surface of revolution are plane curves. Those of one system consist of circles in planes perpendicular to the axis, those of the other system are the *meridian lines*, all equal to the generating curve, and situated in planes which intersect in the axis. The normal at any point of a surface of revolution also intersects the axis. The intercept upon it made by the axis and the surface is one of the principal radii of curvature, whilst the other coincides with the radius of curvature of the meridian line.

Revolution. In Politics, a word of somewhat indefinite meaning, but usually denoting an extensive change in the political constitution of a country accomplished in a short time, whether by legal or illegal means. The term *Revolution*, in English History, is applied by way of eminence to the political change effected in the year 1688, when William III. and Mary acceded to the throne on the forced abdication of James II.

Revolver. A term applied to a fire-arm with several chambers or barrels, which are brought successively under the action of the trigger, or percussion arrangement, so that several shots can be fired without the necessity of reloading.

Rex Sacrorum or **Rex Sacrificulus.** In ancient Rome, an officer answering to the archon basileus at Athens. [Archon.] On this officer those powers seem to have been conferred which the kings had possessed as priests of the nation. As no political influence was attached to the office, the plebs did not care to assert their claims to it, and the rex sacrorum was always elected from the body of the patricians. (Liv. ii. 2.)

Rhabarbarine. [Chrysophanic Acid.]

Rhabdologia (Gr. ῥάβδος, *a rod*, and λόγος, *a description*). The name given by Napier to a method of performing multiplication and division by means of a set of figured rods or scales. [Napier's Rods.]

Rhabdomancy (Gr. ῥαβδομαντεία). Properly, divination by a rod or wand. Some persons have been believed to be endowed by nature with a peculiar sense or perception, by which they are enabled to discover things hid in the earth, especially metals and water. But a more prevalent opinion has been that the discovery of these substances might be effected by means of a divining rod. The divining rod is a branch of a tree, generally hazel, forked at the end, and held in a particular way, by the two ends, in the hands of the adept; and is supposed to indicate the position of the substance sought by bending towards it with a slow rotatory motion, the adept, according to modern practice, being placed in contact with some metallic or other magnetic substance. The art is said to be occasionally practised in the south of France and Italy, under the names of *metalloscopy*, *hydroscopy*, &c. Campetti, an

Italian, in the beginning of the present century, excited much attention by his professed powers of rhabdomancy.

Rhadamanthus. In Mythology. [Minos.]

Rhætizite. A Mineralogical synonym of the Kyanite of the Tyrol (the Rhætian Alps).

Rhamnaceæ (Rhamnus, one of the genera). A natural order of arborescent or shrubby perigynous Exogens, inhabiting all parts of the world excepting the arctic regions. The berries of various species of *Rhamnus*, e.g. *R. catharticus*, are violent purgatives; while the fruit of some species, as *Zizyphus Jujuba*, the Jujube, is harmless and eatable. They are all small-flowered polypetalous or apetalous plants, with four or five stamens alternating with the lobes of the calyx.

Rhamnus (Gr. ῥάμνος). The typical genus of *Rhamnaceæ*, consisting of shrubs or small trees, mostly found in the temperate countries of the northern hemisphere. They are called Buckthorns, and furnish some useful dye plants. The most important commercial product of the genus is the dyeing material used by calico-printers, and known as Yellow-berries, or Persian berries, considerable quantities of which are annually imported from Asiatic Turkey, and from Persia by way of Trebizonde. These are usually ascribed to *R. infectorius*, but they are probably collected indiscriminately from several species—the unripe fruits alone being gathered. From the bark of *R. chlorophorus* and *R. utilis* the Chinese prepare their beautiful green dye, Lo-kao, called in this country Chinese Green Indigo. Large quantities of this Indigo have been imported into Lyons, and used for dyeing silks, the shades of green imparted by it being exceedingly beautiful, especially when seen under the influence of artificial light. A similar dye, however, has since been extracted from *R. catharticus*.

The indigenous Purging Buckthorn, *R. catharticus*, produces little shining black fruits, which resemble corns of black pepper when dry; these were formerly in great demand as a purgative medicine, and are still employed by rustic practitioners, but on account of the violence of their action they have deservedly fallen into disrepute, although Syrup of Buckthorn is still included in our pharmacopœias. The bark likewise possesses active purgative properties. The pigment known as sap or bladder-green is prepared by mixing the fresh juice of buckthorn berries with lime, and evaporating to dryness.

The wood of the Alder Buckthorn, *R. Frangula*, yields the best charcoal for making gunpowder; and the Alaternus, *R. Alaternus*, an evergreen shrub, is grown for ornamental purposes in gardens and shrubberies.

Rhamphastos (Gr. ῥάμφος, *a beak*). The name of a genus of Scansorial birds (*Túcans*) in the system of Cuvier, distinguished by an enormous beak, nearly as thick and as long as the body in some species. The compensation by which this disproportionate beak is rendered manageable and portable is an extremely light and cellular structure internally. It is arcuated near the extremity, and in old túcans is irregularly indented along the edges. The túcans are distinguished from the hornbills by the scansorial modification of their feet, in which two toes behind are opposed to two in front; and by their long, narrow, and ciliated tongue. They are confined to the hot climates of America, where they live in small flocks, feeding on fruit, insects, and the eggs and callow offspring of other birds.

Rhaponticin. [Chrysophanic Acid.]

Rhapsodist (Gr. ῥαψῳδός, from ῥάπτω, *I sew* or *stitch*, and ᾠδή, *a song*). A name given to the minstrels who recited the Homeric poems in Greece, especially before the period at which those poems were first committed to writing. (Grote's *History of Greece*, vol. ii. p. 174 &c.; Gladstone's *Homer and the Homeric Age*, i. 246; Max Müller's *History of Sanskrit Literature*, 502 &c.)

Rhatany (Peruv.). The astringent root of *Krameria triandra*. What is called Savanilla Rhatany is the root of a New Grenada variety of *Krameria Ixina*. [Krameria.]

Rhea (Gr. Ῥέα or Ῥεία). In the Hesiodic *Theogony*, a daughter of Ouranos and Gê (Heaven and Earth), and wife of Cronos, by whom she became mother of Hestia [Vesta], Demeter, Hera, Hades, Poseidon, and Zeus. In the existing Homeric poem she is only named once (*Iliad* xv. 187). At Athens, where the worship of this mother of the gods is said to have been first introduced among the Greeks, her temple was called the Metroum (Μητρῷον), i.e. the house of the mother. The etymology of the name Rhea seems doubtful.

Rhea. The name of a genus of Struthious birds, of which the three-toed ostriches of South America are the representatives.

Rhein. [Chrysophanic Acid.]

Rheometer (Gr. ῥέω, *I flow*; μέτρον, *measure*). A term proposed by Peclet as a synonym for *galvanometer*, and generally adopted by the French writers on physics. Professor Wheatstone, in an ingenious paper entitled 'An Account of several new Instruments and Processes for determining the Constants of a Voltaic Circuit,' published in the *Philosophical Transactions* for 1843, uses the term, in a general sense, to designate any instrument for measuring the force of an electric current, without reference to its particular construction. Mr. Wheatstone also uses the following similar terms in describing apparatus employed in investigations on the same subject:—

Rheomotor (Lat. moveo, *I move*). Any apparatus which originates an electric current.

Rheoscope (Gr. σκοπέω, *I view*). An instrument for ascertaining merely the existence of a current.

Rheostat (Gr. ἵστημι, *I place*). An instrument for adjusting or regulating the circuit, so that any constant degree of force may be obtained.

Rheotome (Gr. τέμνω, *I cut*). An instrument which periodically interrupts an electric current.

Rheotrope (Gr. τρέπω, *I turn*). An instrument which alternately inverts the current.

Rheophore (Gr. ῥέω, and φορέω, *I bear along*). A term employed by Ampere to designate the connecting wire of a voltaic apparatus, as being the carrier or transmitter of the current.

Rhetoric (Gr. ῥητορική, sc. τέχνη, *the rhetorical art*; from ῥήτωρ, *an orator*). In the widest sense in which the word is occasionally used by modern writers, the art of prose composition generally. In the most restricted and most etymological sense, the art of oratory, or of addressing public assemblies. In an intermediate sense, in which, perhaps, it is most commonly employed, the art of argumentative composition. This comes nearest to the signification which Aristotle, the earliest extant writer of a formal treatise on rhetoric, attached to the title of his subject, when he defined it to be the art of discovering and employing topics of persuasion. He arranged these topics or means of persuasion under three heads. First, those which arise from the character of the orator himself; i. e. the character in which, by what must be termed rhetorical artifice, he places himself before his hearers. It is obvious that a speaker addressing an assembly, who is known by them to be actuated by honest motives, and to understand the subject on which he speaks, advances by the mere possession of these adventitious attributes a long way towards the end and aim of oratory, viz. persuasion. Hence it is that Aristotle presents, as one of the chief branches of rhetoric, the art by which the speaker or writer, as it were, invests himself with these attributes, and thus insures a more favourable reception to his argument. The art of moving the passions by the use of such arguments and representations as are proper to excite each belongs also, in Aristotle's arrangement, to this division of his subject. In his second division he treats of argument itself, considered with respect to its cogency or inconclusiveness in point of form; and hence logic, in this point of view, becomes ancillary to, or a subdivision of, rhetoric. The third division of the subject exhibits the modes of persuasion arising from style, arrangement, delivery, and action; and to this third branch writers who have treated of rhetoric in its more limited sense have usually confined themselves.

As the work of Aristotle is the first, so it is the only systematic treatise on rhetoric which the ancients have left us, among whom the art was much more diligently cultivated than among the moderns. Public speaking was of infinitely greater importance in the classical commonwealths than in any modern state; even in our own, where it is most studied and valued, it is but a subsidiary accomplishment. The true momentum of decision, that which convinces or dissuades, lies in the pen of the writer rather than in the voice of the orator; and whilst in the Grecian republics assemblies were actually swayed by oratory to determine on a particular course of action, its principal use now appears to be to arraign, to vindicate, or to explain the actions of individuals. French oratory, from the nature of its subject, is and always was confined within narrow limits. Probably pulpit oratory, in modern European society, answers most nearly to the classical notion of rhetoric; and, had it ever been subjected to systematic rules, would have been found most nearly to conform to those which the ancients have left us. Among the Romans, oratory did not begin to be cultivated as a science until just at the period when its political importance was about to cease. Rhetoric, under the Roman empire, was taught as a regular science; but its practical display was confined to the orators of the forum, among whom the art gradually declined, from the tendency of the civil law, during the last period of its developement, to conduct all process by written rather than oral method. On the other hand, the rules of rhetoric were applied to the construction of declamations, a species of fictitious argument much in vogue during the decline of Roman literature; and of panegyrical harangues. The study of rhetoric, in this perverted sense of the word, i. e. of declamatory speaking or writing, found peculiar favour in the African and Oriental schools of the Roman empire. Some of the early Christian writers, especially Tertullian, afford evident tokens of having acquired the art of composition under such discipline. [ELOQUENCE.]

Rheum (Gr. ῥεῦμα, from ῥέω, *to flow*). A genus of large-growing herbs of great importance in medicine, as the source of the Rhubarb of the shops, and also of considerable culinary value as the source of the Rhubarb of the garden. [RHUBARB.] The former consists of the root of the plants, which is dug, washed, and sun-dried, and then carefully assorted for exportation, its value depending very much on the nature of the climate in which it is produced. It is supposed to be the produce of *R. palmatum*. The latter consists of the succulent leaf-stalks of garden varieties of *R. Rhaponticum* and *R. undulatum*, the latter yielding the delicate-flavoured rhubarbs with red stalks. Though in Queen Elizabeth's time the leaves of Rhubarb were used as a potherb, it was not until the beginning of the present century that the tender leaf-stalks came to be employed for tarts, and were found so valuable for various other culinary preparations. They are excellent, either stewed alone, or with rice; and a capital preserve has been made from them. When too large and old for cooking, they undergo a process by which the juice is expressed from them and made into a delicious wine similar to that from green gooseberries, and closely resembling champagne; indeed, it may be suspected that much of the so-called champagne commonly drunk is no other than a preparation from the stalks of Rhubarb. The juice is stated to contain a large amount of oxalic acid, as well as nitric and malic acid; and it is these which give an agreeable taste to the stalks when cooked, but which render them ill suited to persons of weak digestion.

In the *Gardener's Chronicle* for 1846 (p. 5) Mr. A. Forsyth first directed attention to another part of Rhubarb as being suited for culinary purposes, and to which he gave the name of *Rhaflower*. This is the large globular pouch of unopened flowers, which is described as being of a beautiful colour when dressed in the same manner as Rhubarb, of a milder flavour, and forming altogether a dish of great delicacy.

Rheumatism (Gr. ῥευματισμός). A painful affection of the joints, attended by swelling or stiffness, and affecting chiefly the tendinous and fibrous textures. It is occasionally accompanied by fever, thus becoming *acute rheumatism*, or *rheumatic fever*; in which case the joints are much swollen and excessively painful; the pulse frequent, but seldom hard; the perspiration usually abundant and acid; the tongue extremely foul, and the bowels costive; headache is seldom complained of, and delirium very rare. In this form of the disease a translation or metastasis to the heart is not uncommon. The treatment consists in the use of purgatives, diuretics, and alkalies. Lemon juice has also been used with advantage in acute cases, and opium in large doses is with some a favourite mode of treatment. *Chronic rheumatism* is not in general attended by any very remarkable constitutional symptoms. It occasionally leads to permanent distortion of the joints; affects the periosteum, tendons, and ligaments; and is most common in debilitated habits, when the health has been broken by previous disease or over-exertion of body or mind. These cases come more properly under the head of rheumatic goût. Opium, especially in the form of Dover's powder, is often useful in this disorder to procure rest. The bowels should be kept moderately active by warm purges, and tonics and alteratives cautiously administered. A course of sarsaparilla is often extremely serviceable: colchicum has been resorted to, but with most uncertain success.

Rhinanthus (Gr. ῥίς, ῥινός, *a snout*, and ἄνθος, *a flower*). A genus of annual weeds growing in pastures, the common species, *R. Crista galli*, being known as the Yellow Rattle. They belong to the *Scrophulariaceæ*.

Rhine, Confederation of the. A confederation formed in July 1806 between several princes of the south and west of Germany and the French emperor Napoleon, who was constituted the protector of these states when the latter had separated themselves in perpetuity from the Germanic empire.

Rhinocarpus (Gr. ῥίς, and καρπός, *fruit*). A large tree of Columbia, New Grenada, and British Guiana, belonging to the order *Anacardiaceæ*. It is known in Guiana as the Wild Cashew, and in New Grenada as Caracoli, and yields an excellent tough durable timber, and a pleasant edible fruit. In Panama, according to Seemann, the tree is called Espave, and its bark is said to be used in stupefying fish.

Rhinoceros (Gr. ῥινόκερως, literally *nose-horn*). The name of a genus of Perissodactyle Pachydermal mammals, characterised by one or two horny productions upon the nose. A species of horn-bill is also called rhinoceros, on account of the remarkable recurved horny process which rises from its upper mandible. Six or seven species of rhinoceros now exist, confined to Africa and South-Eastern Asia. In the later tertiary period an equal number of species existed; and in the middle tertiary we have evidence of a hornless form, *Acerotherium*, allied to Hyrax.

Rhinolophus (Gr. ῥίς, ῥινός, *nose*, and λόφος, *crest*). A genus of Entomophagous Cheiroptera in which the nose is prolonged upwards into a cordate or semicircular leaf. The genus is peculiar to the eastern hemisphere. The Horseshoe bat (*Rhinolophus ferrum equinum*) is found in the South of Europe. The *Rhinolophus hippocrepis* has been observed in England.

Rhipipterans (Gr. ῥιπίς, *a fan*; πτερόν, *a wing*). A name proposed by Latreille to supersede that of *Strepsiptera*, by which Kirby designated a new order of insects which he had discovered. The new name has nothing to recommend it, since it signifies a character, founded on the presence of pterygoda, common to other orders of insects, as the Lepidopterans.

Rhizantheæ (Gr. ῥίζα, *a root*; ἄνθος, *a flower*). A class of plants occupying a station between sexual and asexual species, and appearing to be an intermediate form of organisation between Endogens and the lower orders of vegetation. They agree with the former in the presence of sexes, and in their flowers having sometimes a ternary structure; but they have scarcely any spiral vessels, and their seeds appear, as far as they have been examined, to consist of a mass of spores, without a special embryo. In their succulent texture, in their colour, often in their putrid odour when decaying, in the sporuliferous seeds, and in their parasitical habits, these plants resemble *Fungi*; while in their flowers and sexes they accord with *Araceæ*, or similar Endogens. They are in all cases parasites, and destitute of proper leaves, in lieu of which some of them have scales imbricated over their stems. Notwithstanding their parasitical habits, some are of extraordinary size; the flowers of *Rafflesia Arnoldi* are as much as nine feet in circumference.

Rhizobolaceæ (from Rhizobolus, a synonym of Caryocar, the principal genus). A small order of Hypogynous Exogens of the Guttiferal alliance, consisting of tropical American trees. They are proposed by some botanists to form a tribe of the *Ternströmiaceæ*, differing from the other sections of that order, and the allied *Clusiaceæ*, by their digitately compound leaves. The Saouari nuts of the shops, one of the most delicious seeds of the nut kind, are the produce of *Caryocar nuciforme* and *C. butyrosum*, which latter also yields an excellent timber. [CARYOCAR.] The chief features of the order are the digitate leaves, symmetrical flowers, equilateral petals, sessile

stigmas, and solitary seeds, the embryo of which has an enormous radicle.

Rhizoma (Gr. from ῥίζα, *a root*). In Botany, the term applied to a perennial form of stem, which is prostrate and rooting, throwing up leaves progressively. The common garden *Iris* affords a good example of a rhizome.

Rhizophoraceæ (Rhizophora, one of the genera). A natural order of the Myrtal alliance of Epigynous Exogens, found on tropical shores, where they root in the mud, and form a close thicket down to the verge of the ocean. They are distinguished by their polypetalous flowers, valvate calyx, indefinite stamens, many-celled ovary, and flat cotyledons. The principal genus is the Mangrove, *Rhizophora Mangle*, a tree which performs a most important part in the economy of Nature, wresting annually fresh portions of the land from the dominion of the ocean, and adding them to the domain of man. This is effected in a twofold manner: by the progressive advance of the roots, and by the aërial germination of the seeds, which do not quit their lofty cradle till they have assumed the form of actual trees, and then drop into the water with their roots ready prepared to take possession of the mud, in advance of their parent stems. The progression by means of the roots is effected by the new roots issuing from the trunk at some distance above the surface of the water, and arching downwards so as to penetrate the mud, thus establishing themselves as the pioneers of fresh invasions of the retiring element. In this manner the young plants, soon after their descent from the parent trees, continue during their early years to advance steadily forward, till they have attained a height of about fifteen feet, and gained a position considerably in advance of their parent trunks. After this, fewer additions are made to the roots, but the head begins to expand in every direction, spreading its branches on all sides. These branches in their turn send down long slender roots, like those of the banyan-tree, which rapidly elongating descend from all varieties of height, and reaching the water penetrate the mud, becoming independent trees. These mangrove-bogs are the certain indicators of a malarious locality, as they prevent the escape of unhealthy miasma. The trees contain tannin, and the bark has been used medicinally as an astringent. The fruit is said to be sweet and edible, and the fermented juice to be made into a kind of light wine.

Rhizostomes (Gr. ῥίζα, and στόμα, *a mouth*). A genus of *Medusæ*, including those which have the absorbing orifices of their nutrient canals of small size, and situated in great numbers on the branches of arms, or peduncles, extending from the centre of the inferior surface of the disc.

Rhodalose or **Rhodhalose** (Gr. ῥόδον, *a rose*, and ἅλς, *salt*). Red or cobalt vitriol. [BIEBERITE.]

Rhodanic Acid (Gr. ῥόδον). A Chemical synonym of sulphocyanic acid. It produces a red colour with persalts of iron.

Rhodes Wood. One of the names of the West Indian Candlewood, *Amyris balsamifera*.

Rhodium (Gr. ῥόδον, on account of the rose-red colour of some of its salts, especially of the chloride, when dissolved in water). A metal discovered in 1803, by Wollaston, associated with palladium in the ore of platinum. It is of a whitish colour, very difficult of fusion and very hard. Its specific gravity is 12·1, and its atomic weight 52·16. It is represented by the symbol R. It has been used for the points of metallic pens. [PLATINUM.]

Rhodizite (Gr. ῥοδίζειν, *to make red*). A species of Lime-Boracite, which, when heated before the blow-pipe, colours the flame, first green, but afterwards red. It is found, in minute translucent and shining crystals, which are white or inclining to yellow or grey, near Mursinsk in the Ural.

Rhodizonic Acid. A substance formed by passing dry carbonic oxide over highly heated potassium, and acting on the product by water. A red powder separates, which is rhodizonate of potassa, from which rhodizonic acid may be separated by a mixture of sulphuric acid and alcohol. Its formula is said to be $C_{10}H_4O_{12}$.

Rhodochrome (Gr. ῥόδον, and χρῶμα, *colour*). A massive or scaly variety of Kämmererite of a greenish-black colour, found in the island of Tino, in Greece; in the Ural, and at Kraul in Styria.

Rhodochrosite (Gr. ῥοδόχροος, *rose-coloured*). A carbonate of protoxide of manganese, in which the latter is often partly replaced by lime, magnesia, and protoxide of iron. [DIALLOGITE.]

Rhododendron (Gr. ῥόδον, *a rose*, and δένδρον, *a tree*). A genus of evergreen shrubs of the order *Ericaceæ*, remarkable no less for their beauty than for the great variety of aspect which they present. They have monopetalous flowers, varying from bell-shaped to almost flat on the one hand, and narrowly tubular on the other, and in almost all cases produce large showy blossoms, frequently in massive heads. The most important race, so far as garden decoration is concerned, is that consisting of hardy flowering evergreens, which in early summer light up our shrubberies and American gardens with a blaze of brilliant colours. These have been chiefly bred from *R. maximum*, *catawbiense*, and *ponticum*, intercrossed with some of the high-coloured tender kinds. Many Indian species form magnificent conservatory plants, only just too tender to thrive unprotected in our climate. Of these, *R. arboreum* is the best known, and has contributed by hybridisation in no small degree to enrich the colours of the hardy sorts. Many of the tender sorts are deliciously fragrant. The flowers of *R. Edgeworthii* in particular are so fragrant that a few are sufficient to scent a large room.

In the size attained by the species there is a wide contrast. The small and humble *R. lapponicum* is a prostrate shrub, with branches a few inches long; while *R. Falconeri* is sometimes fifty

feet high, with leaves nineteen inches long. The genus is also widely diffused: *R. lapponicum* occurs in the arctic zone; *R. maximum* and *R. catawbiense* are plentiful in some parts of North America; representatives occur in Europe and in China; but the greatest number are found in India, and in the islands of the Eastern Archipelago.

The properties of the *Rhododendron* family are to be looked on with suspicion. It is long since poisonous qualities were first attributed to honey collected by bees from flowers of *R. ponticum*, and the same is reported of some Indian species. Notwithstanding this, an edible jelly is prepared in India from the boiled-down flowers of *R. arboreum*. Goats are said to die after eating the leaves of *R. cinnabarinum*; and the wood, when used as fuel, produces swellings of the face, and inflammation of the eyes. The Siberian *R. chrysanthum* is narcotic.

Rhodoise or **Rhodonite** (Gr. ῥόδον). A silicate of manganese or Manganese-Augite, composed of 54·1 per cent. of protoxide of manganese and 45·9 of silica. It occurs, generally in crystalline and granular masses of a rose-red or reddish-brown colour, south-east of Callington in Cornwall, and at Upton Pyne and Black Down in Devonshire; also in Sweden, Siberia, the Harz, and New Jersey. Rhodonite is sometimes used in a polished state for inlaying. [Allagite.]

Rhodorhiza (Gr. ῥόδον, *a rose*, and ῥίζα, *a root*). A genus of *Convolvulaceæ*, consisting of two small woody plants, found only in the Canary Islands, and by some retained in the genus *Convolvulus*. They are named *R. scoparia* and *R. florida*. The genus derives its name from the rose-like smell peculiar to the root-stock and lower part of the stem, which yield a kind of Rosewood (*lignum rhodii*), from which is distilled the powerfully-scented oil known as *Oleum ligni Rhodii æthereum*, used in some countries for ointment, but more frequently for the adulteration of attar of roses. This Rosewood is called by the French Bois des Rhodes des Parfumeurs, and must not be confounded with the so-called Rosewood of commerce used for furniture. [Dalbergia; Rosewood.]

Rhomb Spar. A crystalline magnesian carbonate of lime. [Bitter Spar.]

Rhombus and Rhomboid (Gr. ῥόμβος, ῥομβοειδής). In Geometry, a parallelogram whose angles are not right angles is called a *rhombus* when its sides are all equal, and a *rhomboid* when this is not the case.

Rhonchus (Gr. ῥόγχος). A rattling or wheezing sound: the term is chiefly applied to sounds occasioned by certain morbid states of respiration, as indicated by the stethoscope.

Rhubarb (Lat. rha barbara, Gr. ῥᾶ). The root of the *Rheum palmatum*, and perhaps some other species, cultivated in Thibet and China for the supply of the drug market. The varieties of rhubarb known in commerce under the names of Russian, Turkey, and Indian rhubarb, are all derived from one source; but the select pieces are sold under the name of Russian and Turkey rhubarb, and those of somewhat inferior quality as East Indian. The varieties found in commerce are very numerous; some are cultivated even in Europe. To judge of the quality of rhubarb, it should be cut or broken: when good, it is of good specific weight, of a mottled reddish or brownish red colour; that which is very pale or very dark coloured, and either so soft as to be spongy, or hard and stony in texture, is bad.

Rhubarb is a valuable article of the *Materia Medica*, being an aperient, and at the same time a tonic and astringent. The average dose of powdered rhubarb, which is twenty grains, leaves after its purgative operation a certain astringent effect upon the bowels; hence its use in diarrhœa: from five to ten grains operates as a tonic, and is very useful in some forms of dyspepsia. A mixture of one part of rhubarb with two of powdered sulphate of potash is an excellent aperient for children. It is occasionally given as a tincture or infusion; but the powder is the favourite form, either in a little plain, or peppermint, water, or in the form of pill. For a full account of the varieties of rhubarb and their respective analyses, the reader is referred to Pereira's *Materia Medica*. [Rheum.]

Rhumb Line (Gr. ῥύμβος, the Attic form of ῥόμβος). In Naval affairs, the track of a ship which cuts all the meridians at the same angle; called also the Loxodromic Curve. This, being the simplest curve, is the route universally pursued; but a ship sailing on this curve never looks direct for her port until it comes in sight.

Rhus (Gr. ῥοῦς, Lat. rhus). A large genus of *Anacardiaceæ*, found abundantly in the temperate countries of both hemispheres. They are for the most part shrubs, and possess poisonous properties of a more or less marked character. Indeed some American species, such as *R. venenata* and *R. Toxicodendron*, produce effects almost rivalling those once fabulously imputed to the Upas-tree of Java (*Antiaris*), the hands and arms of some persons, and sometimes even the whole body, becoming much swollen from simply touching or carrying a branch of one of them, the swelling being accompanied with intolerable pain and inflammation, and ending in ulceration. These effects, however, are not felt by everyone, some persons being able to handle the plants with impunity.

A few of the species yield useful products, such as *R. Coriaria*, the Tanning Sumach, which affords commercial Sumach. This plant is a native of the European countries bordering the Mediterranean, and when allowed to grow to its full size attains a height of fifteen or twenty feet; but in a cultivated state the young shoots are cut off annually for the sake of their leaves, and it is consequently seldom seen higher than four or five feet. The Sumach of commerce consists of the finely ground young leaves: it is extensively employed for tanning and dyeing purposes, from 12,000

to 18,000 tons being annually imported, chiefly from Sicily. *R. Cotinus*, another South European species, called the Venus or Venetian Sumach, yields the yellow dye-wood called Young Fustic, which in olden times was supposed to be the young branches of the true Fustic-tree (*Maclura*).

The Japan Wax recently brought in considerable quantity to this country is the produce of the fruits of *R. succedanea*. *R. vernicifera*, another small Japanese tree, yields the famous lacquer so extensively employed by the inhabitants of that country for lacquering various articles of furniture and small-ware. It exudes from wounds made in the tree, and is at first milky-white, but becomes darker and ultimately black on being exposed to the air. Nothing certain is known respecting the mode of preparing it for use, and it is said that the Japanese themselves have lost the secret of its preparation, for the lacquer-ware at present manufactured is greatly inferior to the ancient.

Rhyme (A.-Sax. gerim, Ger. reim). In Poetry, the correspondence of sounds in the last words or syllables of verses. The latter is the true rhyme of modern European languages. There are rhymed verses in the Latin classical poets, where the jingle seems intentional, and more distinct examples of it in the fragments of Roman military songs, &c. which have come down to us. But in the earlier period of the decay of the Latin language, when accent was substituted for metre in the rhythmical arrangement of the verse, rhyme made its way into the composition of church hymns, &c. It has been attempted, but with little success, to deduce this innovation from the Goths, and from the Arabians; but the former, like the old Teutonic races, probably used alliteration but no rhyme in their verses; and the latter could not have influenced European literature until a period long after that in which rhyme first appears. It has been proved, beyond the possibility of doubt, that rhymed Latin verse was in use from the end of the fourth century. (Hallam, *Literary History*, part i. ch. i. § 35.) A rhyme in which the final syllables only agree (*strain, complain*), is called a *male* rhyme; one in which the two final syllables of each verse agree, the last being short (*motion, ocean*), *female*; and the latter is sometimes extended in Italian poetry to three syllables (*femore, immemore*), when the verse is called *sdrucciolo*. In English such a license is hardly permissible, except in burlesque poetry (see *Hudibras* and *Don Juan* for instances). By the strict rules of French prosody, the male and female species of rhymes must be alternately used, however intricate the disposition of the verse may be, although the last short syllable is generally mute, or very slightly sounded. Rhymes which extend not only beyond the last three syllables, but through the whole structure of the lines, are used in Arabian and Persian poetry. Rhymes in which the consonants of the last syllable in each verse are identical (*dress, address*) are vicious in English, but rather admired in French poetry. One more singularity of English poetry deserves notice. While from the irregularity of our spelling many syllables rhyme with each other although widely dissimilar in orthography (*woo, pursue*), there are, on the other hand, rhymes which speak to the eye, and not to the ear; i. e. in which the orthography of the rhyming syllables is the same, but the pronunciation different; as *wind, find*; *gone, alone*. In the following triplet of Dryden—

'Tis nothing yet; then poor and naked come,
Thy Father will receive His unthrift home,
And thy blest Saviour's blood discharge the mighty sum—

it will be seen that the first and third lines rhyme in a legitimate manner, although the last syllables are differently spelt; while the first and second rhyme to the eye only, and not to the ear. This is a license rendered admissible only by precedent.

Rhynchophores (Gr. ῥύγχος, *a snout*, and φέρω, *I carry*). The name of a family of Coleopterous insects, comprehending those which have the head prolonged in the form of a snout or proboscis.

Rhynchosaurus (Gr. ῥύγχος, and σαῦρος, *lizard*). A genus of Cryptodont Reptiles from the new red sandstone (trias) of Shropshire. The remains indicate a lizard-like animal with the most remarkable shaped cranium, which was edentulous, and resembled that of a bird or turtle. The premaxillary bones were produced downwards in the form of a beak, over the lower jaw, as in *Dicynodon*. Unlike that genus, however, there is no trace of any canine teeth in the upper jaw. The indications of the locomotive extremities denote an animal adapted for motion on land as well as in water.

Rhythm (Gr. ῥυθμός). The consonance of measure and time in poetry, prose composition, and music and by analogy in dancing. Each verse or each period may be considered as a whole, in which the poetical rhythm is regular and exact, within certain limited variations, the rhetorical less perfect, and the pleasure derived from it rather matter of taste and experience than of rule. Those parts which receive the ictus or stress of the rhythm are termed *arsis* (elevation), the remainder form the *thesis* (depression); the former is frequently denoted to the eye by the accent marked ʹ, when in a foreign or unknown word we wish to direct the voice in pronunciation to employ the correct emphasis. The smallest rhythmical division is the foot, by which every union of arsis and thesis is understood. A short syllable is an original unit of time; a long syllable contains two units. The number of feet enumerated in classical writers on metre amounts to twenty-eight, including all the varieties which may be formed out of two, three, or four syllables, long and short, and varying from two to eight units of time. [Foot; Metre; Rhyme.]

Rhythm. In Physiology, the more or less

regular succession of the contractions of certain automatic muscles. In the heart the motion commences in the venæ cavæ, and proceeds through the auricles and ventricles, and then, after an interval, is resumed in the venæ cavæ. In the intestine the movement travels in a vermicular manner from above downwards; and a second movement, beginning at the upper part of the intestine before the first has completed its course, affects the parts in the same order. These movements are called *rhythmic*; those of the intestinal tube are also called *peristaltic*.

RHYTHM. [MUSIC.]

Rial. A gold coin current in the reigns of Henry VI. and Elizabeth: under the former its value was ten shillings, under the latter fifteen shillings.

Rial or **Real.** A Spanish coin. [MONEY.]

Rib (Ger. rippe). The rib of a ship answers in many respects to the rib in an animal frame. The base of the rib is in the keel as a backbone, and it serves to maintain generally the cavity of the vessel. A rib is of massive timber in several pieces scarfed or chocked together. These pieces beginning from the bottom are the cross piece or floor, futtocks, top-timbers, and, if the vessel be of great height, the lengthening pieces. The ribs are otherwise known as the *timbers*.

RIB. In Botany, the principal vein or nervure which proceeds from the petiole into the blade of the leaf.

Ribs. In Anatomy, the lateral appendages of a vertebra, especially when developed so as to encompass the trunk. In the human subject there are twelve pairs of ribs, which, in general homology, are the *pleurapophyses*, the sternal cartilages being the *hæmapophyses*, and the sternum the *hæmal spine*.

RIBS. In Architecture, curvilinear timbers to which, in an arched or coved plaster ceiling, the laths are nailed.

Ribaudequin (Low Lat. ribaudequinus, perhaps from ribaud, ribaudaille—Eng. ribald—the name used to denote all the humbler classes of foot soldiers). A mediæval engine of war, consisting of a cart armed with iron spikes, and after the fourteenth century furnished with small cannon. Such engines are mentioned in the year 1382, as being placed in front of troops arrayed in order of battle. (Christine de Pisan, *Livre des Faits d'Armes*, ch. xxvi. fol. 36; Monstrelet, ch. lxxxiv. p. 206; Brackenbury, *Ancient Cannon in Europe*, p. 36.)

Ribband Shores. Strong supports for the frame of a ship during building. Their heads rest against the ribbands, and their bases on the slip or dock.

Ribbands. In Shipbuilding, longitudinal bands of comparatively thin timber stretching from stem to stern at different distances from the keel. They are bolted on outside the ribs, in order to preserve the proper curvature and to impart stability to the vessel while yet in skeleton.

The ribbands of the slip are square timbers fastened lengthways on the bilgeways, to prevent the timbers of the cradle from slipping outwards during launching.

Ribbon Jasper. A name given to those varieties of Jasper in which the colours are arranged in parallel layers or stripes. The principal localities are Saxony and the Ural; but it is also found in this country near Tortworth in Gloucestershire; in the Pentland Hills; at Arthur's Seat, Edinburgh; in the isles of Islay and Rum, &c. Ribbon Jasper is, in general, a result of the alteration of argillaceous strata by contact with igneous rocks.

Ribes (the Arab name of an acid plant, now ascertained to be *Rheum Ribes*). The botanical name of the genus which yields us the Gooseberry and Currant, whose succulent berries are well known. There are, besides, numerous ornamental flowering shrubs of the same family.

The Gooseberry, *R. Grossularia*, is indigenous to this country, as well as to many other parts of Europe, and has been found, according to Royle, in Nepal. It will ripen in Norway as far north as 66½°, nearly 16° north of London, but will not succeed so far to the south, for even in southern parts of England, under a hot sun, the fruit of some of the varieties becomes as if parboiled. The cooler climates of the North of England and Scotland suit it best. It is an important fruit, furnishing abundantly to millions of the manufacturing population materials for tarts, pies, sauces, &c. at an early period of the season, before any other fruit can be had for these purposes. By competition for prizes in Lancashire and the adjoining counties, the size of the berries has been enormously increased, although some of the old sorts, such as the Red Champagne, are yet unsurpassed in quality. The varieties are exceedingly numerous.

The Currant, *R. rubrum*, is indigenous to Central and Northern Europe, including Britain, Siberia, and Canada. It is to be found wild as far north as Finmark, but, like the gooseberry, it is not suited for so warm a climate as the South of Europe, otherwise it would have extended into Italy, and would have become known to the Greeks and Romans, which does not appear to have been the case. The English name of Currant may be attributed to the similitude of the fruit to the Corinth or Zante Grape, the currant of the shops. Improved varieties of the Currant appear to have been introduced from Holland, and the Red Dutch and the White Dutch are amongst the best in cultivation at the present day. These fruits are always in demand for making wine, tarts, jellies, jams, &c., and the quantities grown for that purpose have greatly increased since the price of sugar has become reduced. The refrigerant juice is also very grateful to the parched palates of persons suffering from fever. The Black Currant, *R. nigrum*, is a fruit much prized for domestic use, both as a preserve and as medicine.

Ribhus. In Mythology. [ORPHEUS.]

Riccati's Equation. An important ordinary differential equation, of the first order

and degree, first investigated by the Italian mathematician Riccati. It is usually expressed in the form

$$\frac{dy}{dx} + ay^2 = bx^n,$$

and is always solvable by a series of double transformations of the form

$$y = \frac{1}{ax} + \frac{1}{zx^2},$$

when n has the form

$$\frac{-4i}{2i \pm 1}$$

where i is either 0 or a positive integer. The equation becomes *linear* by assuming

$$y = \frac{1}{av}\frac{dv}{dx},$$

and to it may be reduced several other differential equations of greater generality. (Boole's *Differential Equations.*)

Ricciaceæ. [HEPATICÆ.]

Rice. [ORYZA.]

Rice Paper. The produce of the *Aralia papyrifera*, a low shrub, with large leaves, from Formosa, where it is wild and abundant. The trunk and branches resemble those of the elder. The pith, dried and rolled or hammered, and pared by sharp knives, forms the paper. It is dyed of different colours, and large sheets are obtained by pressing the smaller pieces together. It is usually sold in small squares of about four inches made up into packets of 100 each, a bundle of five packets being sold for 4*d*. (Swinhoe, *Pharmaceutical Journal* vi. 52.)

Ricinoleic Acid. One of the acids resulting from the saponification of castor oil.

Ricinus (Lat. *a tick*). The best known species of this genus of *Euphorbiaceæ* is *R. communis*, the seeds of which yield Castor-oil. The plant is a native of India, but is now widely distributed over the warmer regions of the globe and throughout the Mediterranean region. It is cultivated with us as an annual, and is known under the name of Palma Christi. In this country the stems do not attain a height of more than from three to five feet; but in Spain, Crete, Sicily, and elsewhere, the plant is stated to become a small tree. There are several varieties of this plant, differing in sundry slight particulars, and amongst others in the size of the seeds. These latter are oval, flattened, of a greyish colour mottled with brownish blotches. The best oil for medicinal purposes is derived from the small seeds, that procured from the large seeds being coarser, and in India employed for lamps and in veterinary practice. The oil is extracted by boiling the seeds and by pressure in an hydraulic press, the latter process yielding the most esteemed oil.

Rickets. [RACHITIS.]

Ricochet Fire (Fr. ricochet). In Gunnery, the fire of a battery placed at right angles to the line of troops or works aimed at; the guns being fired with reduced charge and considerable elevation, so as to give the shot a low velocity and a high curve, in order that it may be brought down immediately after clearing the crest of the parapet, and then by rebounding along the face of the work, dismount the guns or rake the line of troops under cover. It was invented by Vauban, and first employed at the siege of Haarlem in 1572. It arrived at perfection at the siege of Ath in 1697. It gave superiority to the attack over the defence of fortresses.

Riddle. [ENIGMA.]

Rider. A term used to signify any addition to manuscripts or other documents, inserted after their completion.

RIDER. A term used by miners to denote a deposit of ore overlying the principal mineral.

Riders. In Shipbuilding, riders were formerly internal ribs or timbers worked from the kelson as high as the lower deck, to impart greater firmness to the ship's frame. These riders restricted the space in the hold, and have now been generally superseded by bands of iron fastened diagonally on the inside of the ribs.

Ridge (A.-Sax. hricg, Ger. rück). In Architecture, the upper horizontal timber in a roof, against which the rafters pitch.

Riding. The three divisions of the county of York are so termed, by a corruption of the Saxon word *trithing* or *triding* (third part).

Riding Bitts. On Shipboard, massive frames of wood and iron round which the cable is coiled when the vessel rides at anchor. The bitts are bolted through two decks. Large vessels have two pairs: smaller vessels one pair. In inconsiderable merchant ships the windlass is made to do duty for riding-bitts.

Riding Master. A commissioned officer in regiments of cavalry and brigades of royal artillery. He holds the relative rank of lieutenant.

Ridotto (Ital.). A favourite public Italian entertainment, consisting of music and dancing; held generally on fast eves.

Riemannite. A Mineralogical synonym for Allophane, after Riemann, by whom it was first noticed.

Rifacimento (Ital. *re-establishment*). A term in common literary use applied to any work or treatise, the materials of which have not been derived from original research, or collected for the first time.

Rifle. [GUN; RIFLED GUNS; SMALL ARMS.]

Rifle Pits. Holes or short trenches, generally about four feet long and three feet deep, forming, with the earth thrown out in front of them, cover for two men. There is generally a loophole on the top of the breastwork, made by placing two sand-bags with a third resting on them, so as to cover the head and shoulders of the rifleman.

Rifle Regiments. Although the whole of the infantry of the British army is now armed with rifles, the rifle brigade and 60th regiment, which were armed with rifles while the other troops had only smooth-bored muskets,

are still distinguished as rifle regiments, as are also the Ceylon, Cape, and Canadian regiments.

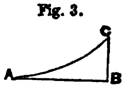
Rifled Guns. Guns in which two or more spiral grooves are cut in the surface of the bore.

The groove of a rifled gun is simply a portion of the thread of a female screw with a long pitch. If A B C be a right-angled triangle (fig. 1), in which BC equals the circumference of the bore of the gun, and A B the length of the bore—suppose the triangle A B C wrapped round the surface of the bore, as in fig. 2, then A C is the *helix* or curve of the groove. But in most rifled guns the *twist*, or inclination of the grooves, is much less than one turn in the length of the bore, and is measured in terms of the length in which one turn is completed. When A C is a straight line, as in fig. 1, the twist is *uniform*; but if A C be curved, as in fig. 3, the groove will have an *increasing* or *gaining* twist, the *angle of twist* C A B becoming greater towards the muzzle. In this case the projectile is easily started, gaining a greater velocity of rotation as it proceeds towards the muzzle of the gun.

Fig. 1.

Fig. 2.

Fig. 3.



The object of rifling a gun is to give the projectile a rotation round an axis coincident with that of the bore. This insures greater accuracy of fire. If a spherical projectile be employed, no other advantages follow; but if an elongated projectile be used, as it can be when thus given a rotation round its longer axis, not only is accuracy increased, but we gain all the other advantages due to this form, which have been described in the article PROJECTILE. Elongated projectiles have, therefore, entirely superseded spherical projectiles for rifled guns.

Both small arms and cannon are rifled; but many difficulties occur in the construction of rifled cannon which are not met with in small arms; especially that of obtaining guns strong enough to resist the enormous strain caused by firing large charges with heavy projectiles [GUN], and the impossibility of using very large shot or shell made of lead alone. SMALL ARMS will be treated separately; we here speak only of rifled cannon.

The conditions which a rifled cannon should fulfil are: (1) to insure accuracy of fire; (2) to give as high velocity as possible; (3) to remain uninjured by much work; (4) to be simple in construction. To insure accuracy of fire, a rotatory motion must be given to the projectile round an axis coincident with that of the bore; the axis of the shot must be stable on leaving the piece; and the shot must have sufficient velocity of rotation (depending on its form, length, and weight) to counteract the tendency which it has to turn over. To give the projectile a high velocity, the gun must be able to stand a large charge of powder; and in order to do this, remaining uninjured, a very strong construction is required. This strength will depend on the quality of the metal used, on its being distributed so as best to resist the strains to which the different parts are subjected, and on the method of rifling not exerting undue strain on the gun. The construction should be so simple that the gun may be easily and rapidly worked, and not liable to derangement.

Breech-loading and muzzle-loading rifled ordnance have each their advocates. The advantages of the former are that a projectile of larger diameter than the bore can be used, and so its axis will be perfectly stable; that the gun can be loaded when run up (the gunners being thus less exposed), and can be worked in a smaller space; that the bore can be easily examined and cleaned; and that a shot is sure to be *home*. Their disadvantages, as compared with muzzle-loading guns, are that the construction is necessarily more complicated; with large guns the breech-loading apparatus is heavy; and they are weaker, weight for weight.

As soon as it appeared that rifled guns would be generally substituted for smooth-bored guns, numerous schemes were brought forward, which may for all practical purposes be classed under one of the four following heads:—

1. Muzzle or breech-loading guns having projectiles of hard metal fitting the bore mechanically.
2. Muzzle-loading guns with projectiles having soft metal studs or ribs to fit the grooves.
3. Muzzle-loading guns with projectiles having soft metal envelopes or cups to be expanded in the bore by the gas.
4. Breech-loading guns, with projectiles coated with soft metal, larger in diameter than the bore, but compressed by the gas into the grooves.

We will first consider some of the most important English systems of rifling. As examples of the first class, in which the projectiles are of hard metal, and made to fit the bore mechanically, we may notice the Whitworth and Lancaster guns. The Whitworth gun has an hexagonal spiral bore, with the corners rounded off. The form of bore and projectile are shown in fig. 4. The Lancaster gun has an elliptical spiral bore (fig. 5). Although it may be scarcely correct to speak of these forms of bore as grooved, it will be seen that a circle, by having in the one case six, and in the other two grooves cut, and the corners chamfered away, can be altered into either of these shapes. In both cases the projectiles are of iron or steel.

Fig. 4.

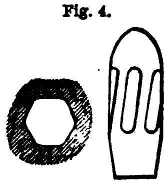


Fig. 5.

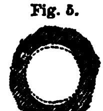


In these systems it is evident that the projectile cannot fit the bore perfectly, and that

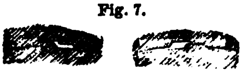
there must be some allowance of windage. If this is reduced too much, there will be great difficulty in loading, and a small quantity of rust or dirt on either bore or shot will render the gun temporarily unserviceable; if, on the other hand, there be too much windage, the shot will not be stable on leaving the bore. Besides this there must be a great tendency to wear out the gun, by the action of the hard metal of the projectile upon it.

It is evident that the chief difficulty with a muzzle-loading rifled gun is to load easily, and yet insure stability of axis of the projectile on leaving the bore. This is ingeniously overcome in the Armstrong shunt gun, which, with the Woolwich system and Scott's, belongs to the second class. A shot in entering a gun with spiral grooves, presses or bears against one side of the grooves; in coming out, against the other side. In the shunt gun the stud for the shot is only about half the width of the groove. The half of the groove on which the shot enters is of uniform depth throughout, and allows some windage; but the half of the groove on which the shot bears in coming out is gradually decreased in depth towards the muzzle by an inclined plane, so that the shot is firmly gripped before it reaches the muzzle, and leaves the bore with a stable axis. A plan of a groove of the shunt gun, and plans of the muzzle, are

Fig. 6.

shown in figs. 6 and 7. The shot is shown going in and coming out. In going in, the shot

Fig. 7.



Shot going in. Shot coming out.

at E is *shunted* into the narrow portion of the groove. The studs for the projectiles of this gun are of copper. Scott's gun has a bore shaped as in fig. 8; the driving side of the studs on the projectile are of zinc, and they enter at the deep portion of the grooves, bearing on the shallow portions as they come out. The Woolwich system is only a slight modification of the French, which will be spoken of presently, the grooves being shallower, and having their corners rounded off. The large muzzle-loading guns in our service are rifled on this system, some having a uniform, and others a gaining twist. In the latter case the studs in the front row are smaller in diameter than those in the hind row, the sides of the studs which bear in loading having no spiral; but the sides which bear coming out having a spiral corresponding to the sharpest twist of the rifling, which is of course next the muzzle (fig. 9). By this arrangement the shot is driven by the hind studs only, until near the muzzle, when both studs act, and the shot is brought into the proper position on leaving the piece.

Fig. 8.

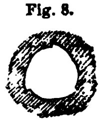


Fig. 9.

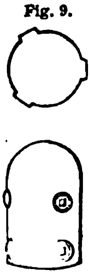
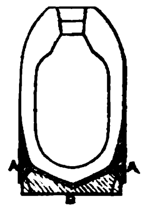


The third class includes the American Parrott gun, Blakely's, Jeffrey's, Lynall Thomas', Bashley Britten's guns. The latter, which may be taken as a good sample of this class, has five shallow grooves; and the projectile, which is made of iron, has a leaden envelope A, and a wooden sabot B (fig. 10). The shell is easily inserted, being smaller than the bore; but when the gun is fired, the sabot is driven against the envelope, and expands the lead into the grooves. Projectiles of this nature will not generally stand large charges, the envelope giving way.

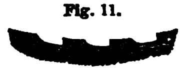
Fig. 10.



Mackay's system is also really of this class. The gun is grooved, and the projectile, which is of iron, is smaller in diameter than the bore. It has neither envelope nor studs, but a large cartridge of sawdust is inserted between the powder and the shot, and is doubtless compressed on the discharge, and jammed between the shot and the bore, thus entering the grooves, and giving rotation to the shot.

The fourth class includes the Prussian gun, and the Armstrong breech-loading guns. The latter have been adopted into our service for all rifled field guns, and several larger natures. The projectile is coated with lead, and is inserted into a chamber behind the bore, of larger diameter than the bore (fig. 13). The bore has a number of small grooves, separated by *lands*, narrower than the grooves (fig. 11). The explosion drives the projectile into the bore, compressing its soft coating into the grooves, and so giving a rotatory motion to the shot. There are two methods of closing the breech; the first by a vent piece, which is dropped into a slot, and pressed tightly against the rear of the powder chamber by a screw; the second by a wedge and stopper, which work in guiding grooves, and are forced in sideways behind the powder chamber.

Fig. 11.



But the peculiar *system* of rifling, or method of giving the rotation, matters but little, so long as the conditions above named are fulfilled; if projectiles of the same form, size, and weight, be fired with equal charges from various guns, having the same *twist*, the results will vary but little, no matter what may be the system of rifling. The great problem to solve is how to construct a gun of sufficient strength to withstand heavy projectiles fired with large charges.

When a charge of powder is ignited in the bore of a gun, the gas exerts a pressure equal in every direction, which forces the shot through the grooves along the bore, and exerts a double strain upon the metal of the gun, a *tangential strain* tending to rend the metal lengthwise

along a line drawn from breech to muzzle, and a *longitudinal strain* tending to fracture the gun across, or to drive out the breech. The *initial strain*, or the strain to which the gun is subjected before the shot moves, is the most severe, for the gas, being then confined in the smallest space, exerts its maximum pressure per square inch; and this *initial strain* generally fractures a gun. Now, the longer it takes to move the shot, the more powder will be ignited before the shot's motion, and the greater will be the initial strain. In a smooth-bored gun the shot is rolled along the surface of the bore, probably when only a very small portion of powder is converted into gas. In a rifled gun there is considerable friction between the elongated shot and the bore, additional work is required to give the shot a rotatory motion, and the area of projectile presented to the force of the gas is much less for a given weight of shot, than with a round shot. Besides, in those systems which have soft coatings or envelopes for the projectiles, additional work is required to compress the soft metal into the grooves. Thus there is much greater difficulty in moving the shot in a rifled gun, and consequently also a much greater strain than on the metal of a smooth-bored gun.

Bronze and cast iron, the metals chiefly employed as materials for ordnance until the introduction of rifled guns, are not suited to withstand this great strain. Bronze, though tough, and, if well made, uniform in quality, is too soft for the bores of guns, and is also very costly; cast iron, although hard enough, is uncertain in tenacity, and cannot alone be used for rifled guns, unless fired with very small charges only. Cast-iron guns strengthened by rings or tubes shrunk or driven on externally, will not stand great strain, but moderately good results have been obtained by lining them with a tube of wrought iron or steel, as proposed by Major Palliser.

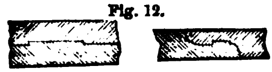
Wrought iron and steel are the metals now almost universally employed for rifled guns. Wrought iron is exceedingly tough, and not liable to snap or to fly into destructive pieces, but it is rather too soft for the bore of a gun, and it is very difficult to obtain thoroughly sound forgings of great size. Cast steel, well hammered, is hard and elastic, but is liable to snap without warning and fly into pieces; it is rendered harder and tougher by being tempered in oil, but there is great difficulty in obtaining large castings of thoroughly uniform quality. Steel is also very expensive.

It has not as yet been found practicable in this country to make large rifled guns in one solid casting of great strength; though in Krupp's works, at Essen, in Prussia, large guns are so made. Even their endurance, however, is not such as would satisfy us in this country. The formation of guns from one solid forging has been advocated, but condemned by many good authorities. The Horsfall smooth-bored gun, made at the Mersey Works at Liverpool, was of this nature. It weighed nearly twenty-five tons, and had a calibre of 13 inches.

The method chiefly employed in this country is to build up guns of several pieces. By this plan several advantages are gained. 1. The parts may be of such a size that their soundness may be depended upon. 2. Different* materials may be used, each being placed at that part of a gun which it best suits. 3. The materials may be applied so that their fibres may run in a direction most favourable to the peculiar strain they will have to withstand. But in this method of construction, great care must be taken to provide against the separation of the parts; and it is evident that the fewer parts there are, the less likely will the gun be to shake to pieces. Whitworth advocates steel for all parts of a gun. His method of building up, as given in his own words, is this: 'The tube of the gun is made taper, then a series of hoops are made, which are screwed on together so as to form another tube, that is put on by hydraulic pressure; each layer is put on a little tighter than the succeeding one.' Blakely is also a strong advocate of steel for all parts of a gun, though he has employed both cast and wrought iron. His method of shrinking on the outer tubes when hot, so that in cooling they contract and grasp the inner tubes, is employed in the manufacture of Armstrong guns, and in the gun factories at Woolwich.

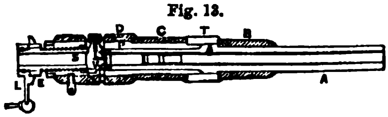
The essential features of the Armstrong method of construction are: 1. The disposal of the fibre of the metal round the bore, by coiling, so as to resist the tangential strain, the welds running in the direction of the least strain as regards separation. 2. The employment of a breech piece to support the bottom of the bore, with the fibre running lengthwise so as to resist longitudinal strain. 3. The shrinking on the different portions, so that the exterior of the gun takes a due share of strain. The different parts of the gun are also now hooked together by means of

Fig. 12.



shoulders and corresponding recesses. Both coiled iron barrels and steel barrels are now used in the royal gun factories, with forged breech pieces and trunnion pieces, and coiled outer tubes. Fig. 13 represents a section of an Armstrong 12-pr. screw breech-loading gun.

Fig. 13.



A A, barrel, coiled iron or steel.
B C D, coiled outer tubes.
P, breech piece, solid forging.
T, trunnion ring, ditto.
V, vent piece.
E, tappet ring.
L, lever ring.
S, breech screw.

The same method of construction, with modifications, has been adopted for our larger guns. Mr. Fraser, of the royal gun factories, has suggested some important improvements, which will both strengthen the gun and lessen its cost.

The principal methods of construction and systems of rifling of this country having now been explained, it remains briefly to mention the rifled guns of the principal foreign nations.

The French have adopted the *système la Hitte*, the shape of the groove and stud in which are shown in the annexed figure. The studs are of zinc, and centre the projectile by means of bevelled driving edges. The French field guns are of bronze; the *canon de 4 rayé*, which is their general service field gun, has the same calibre as the old brass 4-pounder; it has six deep grooves, and the projectile has two rows of studs. Their heavy guns are principally cast iron hooped with steel, and muzzle loaders, with a gaining twist applied to the system above described. They have a few breech loaders, up to, but not over, six inches calibre.

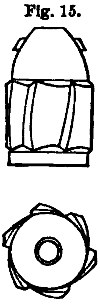
Fig. 14.

The French system has been adopted, with modifications, by Spain, Portugal, Russia, Holland, Switzerland, Würtemburg, and, as already shown, by ourselves for some guns.

The Italians have chosen the French system for their field guns, which are made of bronze up to the 16-pounder; they have some 24-pounder and 40-pounder iron-hooped guns, muzzle-loaders, and a few heavy breech-loading cast-iron Cavalli guns, which were cast in England, and proved at Woolwich.

The Austrian field guns are bronze muzzle-loaders, and the projectiles are covered with zinc and tin (fig. 15) of the same shape as the bore, but one-twelfth of an inch less in diameter. The grooves in the gun may be said to be formed by wrapping a number of triangles round a cylindrical bore. The exterior of the projectile being of the same shape, the latter enters the bore easily and is pushed home, riding on the bases of the triangles, with windage above and at the sides. A slight turn with the rammer, acting on small drivers left on the head of the shell, centres it, so that it comes out with its axis coincident with that of the bore, and windage equally distributed, viz. a small space at the base of each of the triangles. The projectile for what is called the 4-pounder field gun weighs about 8 lbs. English, and the gun itself about 582 lbs. The Austrians have lately made a number of breech-loading cast-iron guns for siege and garrison purposes, on the old Prussian system, the *Kolben verschluss* of Wahrendorff. A cylinder, introduced through a hole at the side of the breech, fits into a corresponding orifice in the breech stopper, thus preventing the latter from being driven back; but this cylinder frequently becomes jammed, and the action of the arrangement cannot therefore be considered successful. They have also bought some of Krupp's guns, rifled and with his patent breech-loading arrangement. At one time they introduced several batteries of rifled guns for gun cotton, but in the autumn of 1862 these were abandoned, and the present system introduced. The *système la Hitte* had been previously tried and condemned.

Fig. 15.



The Prussians have a few 24-pounder bronze breech-loaders on their new system (Krainer's), throwing shell weighing about 60 English pounds; and some 6-pounders and 12-pounders throwing projectiles of 15 lbs. and 32 lbs. respectively. For field guns they have entirely adopted the breech-loading system and steel guns. The latter are cast and hammered by Krupp, of Essen, and afterwards bored and rifled at Spandau near Berlin. The 4-pounder is the field gun of the Prussian service, the projectile weighing about 9½ lbs. English. The breech is closed by a double wedge which works at the side, as in our own wedge system. Into the face of the front wedge fits a loose steel cup to take the first shock of the discharge, and to contain a copper ring valve, so arranged as to be pressed closer to the back of the bore by the gas. This can be taken out and cleaned, or replaced by another almost instantaneously.

Krupp's system, which is both simple and strong, has been partially adopted by many powers. The breech is closed by a single thick steel wedge, which slides in and out easily, and is driven firmly home, after it has been pushed in, by a lever and screw, the latter working half in the breech and half in the gun. The recess in the wedge corresponding to the steel cup in the Prussian system contains a copper ring valve like that in the Prussian system. In both these systems (Krainer's and Krupp's) the gun is multigrooved, and the projectile has a soft metal coating with three raised rings of the same material.

The Russians, in addition to guns on the modified French system, have bought the heaviest Krupp's guns yet made, of 11 inches calibre, about 540-pounders, for Cronstadt. They have also several American guns, a few shunt guns, and some Blakely guns. A committee held in 1865, of which General Todleben was president, has decided that steel 8·58 calibre breech-loading guns are to be adopted for coast defences; that they are accurate, good against armour plate, and stand 425 rounds at least; but that Krupp's muzzle-loading guns of large calibre cannot be considered safe after 250 rounds have been fired from them. Broadwell's system of breech-loading, a modification of Krupp's, will probably be definitely adopted.

The Turks are arming their ships principally with Armstrong's guns.

The Japanese have purchased fifty of Krupp's six-inch guns.

The Swedes have tried Wahrendorff's breech-loading system, but both they and the Danes are settling down to the definite adoption of muzzle-loaders on a modification of the shunt system. All their ordnance are cast iron, but some pieces will be strengthened by internal steel tubes.

The Americans have a great variety of pieces; their navy still favours cast-iron smooth-bored guns of large calibre. Some twenty-inch guns have been made, a pair of which are fitted to the 'Puritan' ironclad, a park of them being also in readiness for land service; but these will only stand comparatively small charges, although by a method of cooling from the interior, invented by Rodman, greater strength is obtained in the cast iron of which they are made. Their rifled Parrott guns, which are made of cast iron strengthened with wrought-iron hoops, were of much service during the war, though several cases of bursting occurred. A committee on ordnance has recommended the Ames gun, which is built up of wrought iron. No breech-loading system is in favour in America, their plan being generally, as in the Parrott gun, a ring of brass at the base of the projectile, which is expanded by the gas into the grooves; or, as in the Schenkel system, a papier-mâché detached wad, which takes the rotation, and transfers it to the projectile.

On comparing the rifled ordnance of foreign powers with that of our own country, we have no reason to be dissatisfied. Our guns, being made of wrought iron, will not, on failure, break up like cast iron or steel ordnance; and from their accuracy of fire, the capacity of their shells, and the power which the latter have, owing to their elongated form, of maintaining a high velocity, obtained from the large charges which we are able to use, they are certainly not surpassed by those of any other nation.

For further information, the reader is referred to Major Owen's *Lectures on Artillery*, 4th edition. For minute details, it is necessary to consult professional papers, bluebooks, &c.

Rig (A.-Sax. wrigan, *to dress*). The peculiar manner of fitting the masts and rigging to the hull of any vessel; thus the terms *schooner rig*, *ship rig*, &c., imply the masts and sails of these vessels without regard to the hull.

Rig Veda. [VEDA.]

Rigging. On Shipboard, the system of cordage by which the masts are supported, and the sails extended or taken in. The rigging is hence divided into *standing rigging* and *running rigging*. The standing rigging consists of the *pendants*, short strong ropes first put over the lower mast heads, and having thimbles for hooking tackles to; the *shrouds*, *stays*, and *backstays*. The lower rigging implies that of the lower masts, the topmast rigging that of the topmast, and so on. The running rigging comprises the lifts for raising and lowering the upper masts and the yards, the braces for trimming the yards, the halyards for hoisting flags, &c., and the clew-lines, sheets, tacks, and guys used in managing the sails. The size, strength, number of ropes &c. of the rigging, are all matters determined by experience.

Rigging Loft. The room or rooms in which the rigging is prepared and tested.

Right (Ger. recht, akin to Lat. rectus). In Geometry, a term applied to certain figures which are deemed to be the simplest of their kind. Thus a *right line* is one whose direction never varies; the more common term is *straight*. A *right angle*, again, is formed by two straight lines which intersect each other in the most symmetrical manner; i.e. in such a way as to divide the whole angular space around their point of intersection into four equal parts. Similarly, a *right prism* is one whose edges are perpendicular to the plane of its base, whilst in a *right cylinder* and *right cone* the base is a circle whose plane is perpendicular to the axis of symmetry. In these cases, as in many others, the term *right* is opposed to *oblique*.

Right Ascension. In Astronomy, the angle formed at the pole of the equator by two great circles, one of which passes through the first point of Aries, and the other through a celestial body; it is consequently measured by the arc of the equator intercepted between those circles. *Right ascension* and *declination* are the two coordinates to which the positions of celestial objects are for the most part referred. It is sometimes convenient, however, to give their latitudes and longitudes.

Right, Divine. [DIVINE RIGHT OF KINGS.]

Right, Petition of. A declaratory enactment passed by the parliament of 1628. This name was adopted by the framers, who wished to imply by it that the franchises therein specified were not newly acquired, and that the law was merely explanatory of the ancient constitution. It was calculated to protect the subject against forced loans, benevolences, taxes imposed without consent of parliament, arbitrary imprisonments, &c. Much delay and some evasion took place before Charles I. could be induced to give the royal assent to this measure.

RIGHT, PETITION OF. This term also denotes the process by which a subject may obtain possession or restitution from the crown of either real or personal property. The proceedings upon it have recently been simplified (23 & 24 Vict. c. 34), and assimilated in many respects to the course of an ordinary action between subject and subject.

Rights, Bill of. [BILL OF RIGHTS.]

Rigidity (Lat. rigiditas). In Mechanics, a resistance to change of form. In theoretical investigations respecting the application of forces through the intervention of machines, the latter are frequently assumed to be perfectly rigid, so far as the forces employed are able to affect their integrity of form and structure. Rigidity is often, in the arts, called *stiffness*, and is opposed to flexibility.

Rigor Mortis (Lat.). In Physiology, the general stiffening of the body produced by the simultaneous contraction of all the muscles of the trunk after death. The muscular coat of the arteries also contracts after death, on division and mechanical irritation, on the application of cold, and under the stimulus of electricity.

Rilievo. [RELIEF.]

Rimose (Lat. rimosus, from rima, *a fissure*). In Zoology, when the surface of an animal or part resembles the bark of a tree, having numerous minute, narrow, and nearly parallel excavations which run into each other.

Rinderpest or **Cattle Plague.** The Report of the Cattle Plague Commission (May 1866) renders it necessary to make a few remarks in addition to those already made in the article MURRAIN. Although no unfailing specific has been discovered, some facts have been ascertained which throw considerable light on the pathology of this disorder. It appears that within forty-eight hours of the time when the animal has imbibed the disease, the temperature of the body rises from two to three and a half degrees of the thermometer. The period of incubation is thus shown to be shorter than was generally supposed, and this rise of temperature is especially valuable as furnishing a means of separating sick from healthy cattle, and shortening the time of quarantine. The whole course of the disease is seven days; but hitherto it has been erroneously treated as beginning when it has already existed for four days, and obtained a fatal hold on its victim. It is confined almost entirely to ruminating animals, although it may exist in the sheep and goat. The commissioners unanimously report that it is propagated only by contagion, and that it consists in a poison generated in the blood and capable of being conveyed by inoculation, the increase of the poisonous matter when the disease is once established being marvellously rapid. For the purpose of disinfection they recommend chlorine and the acids obtained from tar and sulphur. Inoculation and vaccination with the matter of the cow-pox have been tried as a preventive without success. All strong medicines, it is asserted, heighten the mortality; and the only remedies suggested are cleanliness, ventilation, disinfection, and careful feeding. If these conclusions accord with the facts, the necessity of a strict quarantine becomes imperative for all cattle arriving from foreign ports.

In their third and final report, issued June 1866, the commissioners adhere to their former conclusions as supported by microscopic and other experiments. Having used the highest magnifying powers, Dr. Beale considers that 'with regard to the nature of the contagion itself, evidence has been adduced to show that it consists of very minute particles of matter in a living state, each capable of growing and multiplying rapidly when placed under favourable conditions; that the rate of growth and multiplication of these minute particles far exceeds that at which the normal germinal matter of the blood and tissues multiplies, and that they appropriate the pabulum of the tissues, and even grow at their expense.'

The most efficient disinfecting agents, sulphurous and carbolic acids, are supposed to act by destroying the vitality of the poisonous particles emanating from animals in a state of disease. On the whole, the commissioners are convinced of the necessity of treating the disease as strictly contagious, and of the importance of marking the rise of the natural temperature of the animal as the first and surest symptom that the disorder has begun.

Rinforzando (Ital. *strengthening*). In Music, a direction to the performer, denoting that the sound is to be increased. It is marked thus < ; and is also expressed by the abbreviation *rf.*

Ring (A.-Sax. hring). A solid body generated by a circle whose centre describes a closed curve to which the plane of the circle is always normal. The radius of the generating circle is usually constant, so that the ring is enclosed by a TUBULAR SURFACE. Ordinarily, too, the locus of the centre of the generating circle is itself a circle. [ANNULUS.]

Ring of an Anchor. The ring, bolted into the top of the shaft, to which the cable is made fast.

Ring Bone. In Farriery, a callus growing in the hollow circle of the little pastern of a horse, just above the coronet.

Ring Sail. A small and light sail set on a mast on the taffrail. Also a studding sail set upon the gaff of a fore-and-aft sail, and stretched on the ring-tail-boom. It is very rarely used.

Ring of Saturn. [SATURN.]

Rings, Fairy. [FAIRY RINGS.]

Rings, Meteoric. [METEORS, LUMINOUS.]

Ring-bolt. On Shipboard, a strong iron ring passing through a hole at the end of an iron pin, which is clinched through the beams of the deck or the side. The principal use is to give bearing to the tackle for running the guns in and out.

Ring-ropes. Auxiliary ropes bearing on ring-bolts in the deck, and temporarily fastened to the cable at different parts in very heavy weather, to furnish a more powerful hold on it while diminishing the strain on the riding bitts.

Ringworm. This disease is of two kinds, viz. the ringworm of the body and the ringworm of the scalp. The former is a vesicular eruption (*Herpes circinatus*), and is not contagious; while the latter is a pustular form of disease (*Porrigo scutulata*), and so contagious as to prove a scourge to any public establishment into which it may be introduced. The ringworm of the body is by no means a very manageable disease: it is to be treated by attending to the general health, and by applying astringent mineral lotions. The ringworm of the scalp is a most obstinate affection. It begins with clusters of little pustules, which form scabs, leaving a red pimply surface, and destroying the roots of the hair as the disease proceeds

(which it never fails to do if not prevented) over the greater part of the head. It is most common in children of a feeble flabby habit; but as it is communicable by contagion, it spreads rapidly in schools and families by the frequent contact of the heads of children, or by the use of the same caps, combs, towels, &c.: so that when it once appears, the diseased children should be strictly removed from the others. The treatment consists in shaving the head, and using frequent and regular ablutions in the first instance, sponging the part with weak soap-and-water; when the scabbing begins, other applications must be used, the selection of which must entirely depend upon the degree of irritation and other circumstances. Solutions of nitrate of silver, sulphate of copper, iodide of potassium, or of iron, pitch and tar ointments, petroleum and naphtha, mercurial ointments of different kinds, various other stimulants, as also sometimes sedatives, are resorted to, to get rid of the morbid state of the part; but so whimsical and obstinate is the disease, that it is impossible to lay down any mode of treatment which can be considered as approaching to a specific. Except in particular cases, no internal medicine has appeared to be of use.

Riolite. A native selenide of silver found at Tasco in Mexico, and named after Del Rio, by whom it was analysed.

Riot (Ital. riotta). In Law, a tumultuous disturbance of the peace by three persons or more assembling together of their own authority in order to assist each other, against anyone who shall oppose them, in the execution of a private purpose, and afterwards executing the same in a violent and turbulent manner. A *rout* is said to be a disturbance of the peace by persons assembled together to do a thing, which, if executed, would make them rioters, and making some motion towards that object: an *unlawful assembly* is a similar disturbance by persons who neither execute their purpose, nor make any actual motion towards the execution of it.

Ripidolite (Gr. ῥιπίς, *a fan*, and λίθος, *stone*). The name given by Von Kobell to a green Chlorite occurring in grouped folia, at St. Gotthard, at Rauris in Salzburg, and in the Zillerthal. It is a hydrated silicate of alumina, protoxide of iron and magnesia, and is found at Penrhyn in Caernarvonshire, and in Argyleshire; also in Dauphiny, the Ural, the Harz, the Alps, and at Gumush-dagh in Asia Minor.

Ripieno (Ital.). In Music, a term signifying *full*, and used in compositions of many parts, to distinguish those which fill up the harmony and play only occasionally, from those that play throughout the piece.

Ripple Marks. The peculiar undulated marks, left by the receding waves on the sea beach, which are occasionally found in some of the older strata of rocks, and are considered as announcing a similar action at a remote period. The wind blowing over a sandy district sometimes occasions a similar appearance.

Rishis, The Seven. In Sanscrit Mythology, the seven sages who were supposed to dwell in the seven stars of the constellation known by us as the Great Bear. This notion belongs to that large class of legends which spring up from the partial or total forgetfulness of the original meaning of a word. Such misapprehensions, it is obvious, must arise when families and tribes diverge from a common centre, carrying with them a number of words expressive of sensible or material notions. Such words would assume more and more the character of personal appellatives, the extent of the change being determined by the measure in which the original force of the word was remembered. Thus such names as Endymion and Anadyomene are even in later legends little more than epithets; but the Greek Argynnis became a maiden beloved by Agamemnon, whereas the Sanscrit *arjunî* remains a simple epithet denoting beauty. But when such words had sunk into mere proper names, they were liable, by a process common to all languages, to be confounded with other words which they might happen most nearly to resemble in sound. The result would be, in grammatical phrase, false etymology; the practical consequence would be the growth of a myth. From a root which meant to shine, the Seven Ṛikshas, or shiners, received their name; and to the same root probably belongs the name of the golden bear, the Greek ἄρκτος, and Latin ursa, as the Germans gave to the lion the title of goldfusz; and thus when the epithet had by some tribes been confined to the bear, the seven shiners were transformed into seven bears, then into one bear with Arcturus for their bearward. In India also the meaning of ṛiksha was forgotten; but instead of referring the word to bears, the people confounded it with rishi, *wise*, and the seven stars or shiners became the abode of seven sages or poets. The same lot befel another name for this constellation. They who spoke of the seven *triones* had long forgotten that their fathers spoke of the stars as *târâs* (staras), or strewers of light, and converted the bearward into Boötes, the ploughman; while the Teutonic nations, unconscious that they had retained the old root in their word *stern* or *star*, likewise embodied a false etymology in wagons and wains. (Max Müller, *Lectures on Language*, second series, viii.; *Westminster Review*, January 1865, p. 48.)

Rising Line. On the sheer-plan and other draughts of a ship, a curved line marking the height of the floor timbers throughout the length, and thereby fixing the sharpness and flatness of the vessel's bottom.

Rising Wood. In Shipbuilding, the portion of the keel let into the floors.

Risus Sardonicus (Lat. *the sardonic laugh*). A convulsive grin, giving a peculiarly horrible expression to the countenance, chiefly

observed in cases of tetanus and inflammation of the diaphragm. It has been generally supposed to have been so named, as being produced by eating a species of ranunculus growing about certain springs in Sardinia; but this derivation is far from probable, and the Greek phrase *σαρδάνιον γελᾶν* indicates merely a grim, bitter laugh, and points to the verb *σαίρω*, to grin or sneer.

Ritornello (Ital. *a return*). In Music, properly a short repetition, such as that of an echo, or of the last words of a song, especially if such repetition be made after a voice by one or more instruments. But by custom this word is now used to denote all symphonies played to a song before the voice begins or after it ends.

Rittingerite. A mineral found at Joachimstahl in Bohemia, and named after Rittinger, an Austrian officer of mines. It is a sulphide of silver and antimony.

Ritual (Lat. ritualis, from ritus, *a rite*). A book in which the different rites or services of the church are contained.

River Systems. So far as rivers depend for their water supplies on the rain falling on the land through which they run, it is clear that each river, whether entering the ocean, or terminating in an inland sea or lake, or losing itself in a sand desert, may be regarded as including the natural surface drainage of the whole tract of land through which runs every branch of the river and all its tributaries, whether large or small. Thus the greater part of a continent may be grouped into a few districts, each designated by the principal rivers running through it. Every such district is called in physical geography a *river basin*; and the whole group of streams having one outlet is denominated a *river system*. Those which connect with the ocean are called *oceanic*; and those not reaching the ocean, *continental*. The line separating two such districts is the line of *watershed*, from the German *wasserscheide* (water-parting).

The principal river systems of the world are named in the subjoined table, and the details of the more important will be found referred to in separate paragraphs.

River Walls. Works executed to defend the shores of rivers are commonly known as river walls, whether they are walls in strictness of speech, or only an inclined fore shore with a paved slope towards the river. Examples of the latter kinds may be seen on the banks of the Thames, the Severn, the Seine, the Orne, the Rhine, the Rhone, &c. But in the midst of the great centres of population it becomes necessary to economise space, and *walls* are used, more or less inclined to the water, of which a good example is to be found in the Thames embankment. The principles on which these are founded are that a sufficient space should be left for the water-way, so as not to produce any scour likely to injure the bank, and to insure the resistance of the materials employed in the composition of the walls. [SEA AND RIVER DEFENCES.]

Rivers (Lat. rivus, the root being found in Sansc. sru, Gr. *ῥέω, to flow*). In Physical Geography, an inland current of water, formed within a certain portion of the earth's surface by the confluence of brooks, small streams, or mountain torrents, and discharging itself into the ocean, a lake, a marsh, or another river. There are few subjects in physical geography which present so wide a field for speculation as rivers, whether we regard them in an historical, political, economical, or scientific point of view. They are associated with the earliest efforts of mankind to emerge from a state of barbarism; but they are no less serviceable to nations which have advanced in civilisation. In the earliest ages they were regarded with veneration, and became the objects of a grateful adoration, surpassed only by that paid to the sun and the host of heaven. Nor is this surprising; for in countries where the labours of the husbandman and shepherd depended for a successful issue on the falling of periodical rains, or the melting of the collected snows in a far-distant country, such rivers as the Nile, the Ganges, and the Indus were the visible agents of nature in bestowing on the inhabitants of their banks all the blessings of a rich and spontaneous fertility; and hence their waters were held sacred, and they received, and to this day retain, the adoration of the people through whose land they flow. But it is by countries which have already made progress in civilisation (to which, indeed, they largely contribute) that the advantages of rivers are best appreciated, in their adaptation to the purposes of navigation, and in their application to the useful arts. Like the veins and arteries of the human body, which convey life and strength to its remotest extremities, rivers vivify, maintain, and excite the efforts of human industry; whether we regard them near their source as the humble instruments of turning a mill, or in their progress as facilitating the transport of agricultural or manufacturing produce from one district to another, or as enriching the countries at their mouths with the varied products of distant lands. This has been admirably expressed by Pliny. 'The beginnings of a river,' he says, 'are insignificant, and its infancy is frivolous: it plays among the flowers of a meadow; it waters a garden, or turns a little mill. Gathering strength, in its youth it becomes wild and impetuous. Impatient of the restraints which it still meets with in the hollows among the mountains, it is restless and fretful; quick in its turning, and unsteady in its course. Now it is a roaring cataract, tearing up and overturning whatever opposes its progress, and it shoots headlong down from a rock; then it becomes a sullen and gloomy pool, buried in the bottom of a glen. Recovering breath by repose, it again dashes along, till, tired of uproar and mischief, it quits all that it has swept along, and leaves the opening of the valley strewed with the rejected waste. Now quitting its retirement, it comes abroad into the world, journeying with more prudence and discretion through cultivated fields, yielding to circumstances, and winding round that which it would be troublesome to overwhelm or remove. It passes through the populous cities, and all the busy haunts of man, tendering its services on every side, and becomes the support and ornament of the country. Increased by numerous alliances, and advanced in its course, it becomes grave and stately in its motions, loves peace and quiet, and in majestic silence rolls on its mighty waters till it is laid to rest in the vast abyss.'

Many large rivers have their origin in elevated mountains, or on high table-lands, the height and direction of which chiefly determine their size and course. For information on some of the points involved in this subject, we refer the reader to the article on RIVER SYSTEMS. We shall in this place confine our remarks to some of the most striking peculiarities of rivers, such as *periodical inundations, engulfment*, and *reappearance*.

The periodical inundations of rivers depend on great falls of rain in mountainous regions, or on the melting of snows in the neighbourhood of their source. The period depends on the return of these seasons in different places. Within the tropics, the rainy season occurs usually about the time when the sun passes the meridian towards the tropics; and continues until his return to the same place. The rise of the Orinoco commences in May, its inundation

begins in June, and the waters return to their channel in September; from which time they decrease until April of the succeeding year. In the Lower Mississippi, whose inundations begin in March and are at their height in June, are found those enormous rafts of driftwood (formed during the inundations), which sometimes extend for ten or twelve miles in one mass, rising and falling with the stream, yet having a luxurious vegetation on their summits. The great rivers of Asia—the Ganges, the Indus, the Tigris, and Euphrates—have also their periods of inundation, depending on the circumstances which determine the setting in of the rains on the mountains in which they originate. In the Ganges the waters begin to increase in April, and at the end of July the country, for a hundred miles along its banks, presents the appearance of a vast lake interspersed with insulated villages and woods. But of all inundations, those of the Nile are the most celebrated, nor is it possible to find anywhere among terrestrial objects a more striking instance of the stability of the laws of nature, than the periodical rise and fall of this mighty river. We know by the testimony of antiquity that the inundations of the Nile have been the same, with respect to their season and duration, for more than two thousand years. Indeed, their certainty regulates the public revenue; for when by means of nilometers it is ascertained that the waters promise an unusually prosperous season, the taxes are proportionally increased. Shortly after the commencement of June, the river begins to rise, and it attains its greatest height in August. At Cairo the greatest rise is twenty-eight feet; but in the valley of the Nile, with a mean breadth of three or four leagues, it is only four feet. It decreases gradually until the following May; and as soon as the waters are within their usual channel, the soil, moistened and enriched by the sediment deposited from the inundation, is diligently cultivated by the natives. (Pliny, *Hist. Nat.* lib. v. 9.)

The subject of *the engulfment and reappearance* of certain rivers has attracted attention in every age. In some cases the phenomenon is accounted for by the spongy nature of the soil through which such rivers flow; thus the Guadiana, one of the largest rivers in Spain, suddenly disappears in the marshes near the village of Castillo de Cerrera, and after pursuing a subterraneous course for twelve or fourteen miles bursts again into day. Limestone districts afford many specimens of this phenomenon; one of the most striking of which is the occultation of the Rhone near the gorge called the *Perte*. There are also some curious instances in Derbyshire and Yorkshire. But no country surpasses Greece in the number of its subterranean streams, the peculiarities of which are often clothed in splendid mythological fictions by her ancient bards. The waters of many valleys in the Peloponnesus have no other outlets than ζέρεθρα, or chasms, which engulf them; such are the outlets of the valleys of Tegea, Mantineia, Stymphalus, Peneius, &c. A familiarity with such phenomena, and a poetical temperament, readily led the ancient Greeks to conceive still more distant secret communications; and the imagination which peopled every grove, and animated every stream with presiding deities, could easily reconcile itself to the story of the river god Alpheius, who was said to pursue his favourite nymph Arethusa beneath the bed of the ocean from Greece to the shores of Sicily. The real cause of the apparent mystery may always be found in the rocks over or among which the stream passes.

Rivose (Lat. rivus). In Zoology, a term signifying that the surface of an animal or part is marked with furrows which do not run in a parallel direction, and are rather sinuate.

Rixdollar (a corruption of Ger. reichsthaler, *dollar of the empire*). A silver coin of different values in different countries. [MONEY.]

Roach. The curve, or arch, which is generally cut in the foot of some square sails, from one clew to the other, to keep the foot clear of stays and ropes.

ROACH (A.-Sax. hreoce). A fresh-water fish, *Cyprinus rutilus* of Linnæus; *Leuciscus rutilus* of Yarrell. It is characterised by having twelve reddish rays to the anal fin, and the ventral fins very obtuse. It is found in all the fresh waters of Europe, like its congener the dace (*Leuciscus albus*).

Road or **Roadstead.** A place of anchorage distinguished from a harbour by being at some distance from the shore. A good roadstead is one protected from the prevailing winds, and from ocean swells: an open roadstead, one without such protection. A vessel when at anchor is termed a *roader* or *roadster*, in contradistinction to another under sail.

Road Metal or **Road Material.** The stone used for paving purposes. In places where the traffic is only moderately great, and funds are not abundant, it is usual in England to make what are called macadamised roads with material collected from the adjacent fields or quarries. In the large cities, however, it is necessary to resort to the hardest and best material, often obtained at great cost from a distance.

The properties required by a good road material are these: (1) hardness with toughness; (2) inability to be chemically acted on, or decomposed, or disintegrated by weather; and (3) the preservation of a rough surface during wear. Without toughness the hardest stones become easily cracked, broken down, and worn into powder by the hoofs of horses and the wheels of carriages; if acted on by acids or weather, they are soon destroyed, and if they wear smooth they become slippery and unfit for use.

Certain kinds of granite best combine these properties, and the syenite of Guernsey is the best at present known. It is a fine-grained uniform material, very durable and always rough. Many other granites, as those of Grooby, are used with advantage, and many

granites unfit for road metal are yet very valuable for flags and kerbs. There are some varieties of quartzite sufficiently tough to serve as valuable road metal; of these, the Atherstone is highly spoken of. After granites, greenstones and other volcanic rocks come in. They are often as hard, but rarely so tough or so certain to present a rough surface, as the best syenites.

Roads (A.-Sax. rade). Pathways formed through a country, by which passengers and commodities may travel, or be transported, with more or less facility and expedition, from one place to another. Roads are of various kinds, according to the state of civilisation and wealth of the country through which they are constructed, and according to the nature and extent of the traffic to be carried on upon them—from the rude paths of an aboriginal people, carried in direct lines over the natural surface of the country, passable only by foot passengers or pack-horses, to the comparatively perfect modern road, carried on an artificial causeway, and reduced to a nearly level surface at enormous expense by means of vast excavations, extensive embankments, bridges, viaducts, tunnels, and other expedients supplied by the skill and ingenuity of the civil engineer.

Advantages of Roads.—There is no expedient which more powerfully conduces to the advancement of a people in civilisation, or to the extension of their prosperity and national wealth, than the construction of good roads, connecting the various centres of commerce and industry about which they may have collected themselves. The invention of printing, and of coined money, the adoption of a uniform system of weights and measures, would severally be ineffectual, or would produce but slender results, if the intercommunication of the men whose feelings and ideas are expressed in print, and among whom money is made to circulate, and whose commerce is stimulated by the uniform module of quantity supplied by weights and measures, were not facilitated by the means of conveyance supplied by roads. Without roads, indeed, large towns or cities could not continue to exist. The supply of population collected in such places with the various products of agriculture necessary to their physical existence, could not be maintained. Nor, on the other hand, would the rural population affording that supply be benefited by a return, in exchange, of the refinements of the town, and the various articles of luxury and necessity obtained by commerce from every part of the globe.

But roads are not less necessary for the advancement of agriculture itself, than for the due maintenance of the necessary relations between the towns and the country. Without the aid of roads, it would be impossible to apply those arts to the soil by which increased powers of production are given to it. Without roads, the various kinds of manure, by which the scientific farmer knows how to raise augmented crops, could not be transported to his fields from the place, often distant and difficult of access, where such manures are found. Roads may then, in fact, be considered as a system of veins and arteries, by which all the principles necessary for the maintenance of the prosperity of a country are kept in circulation.

History of Roads.—The importance of roads to the welfare of nations was not unknown to the ancients. The senate of Athens, the government of the Lacedemonians, the Thebans, and other states of Greece, bestowed much care upon them; but, as might naturally be expected, the first great advances in the art of intercommunication by roads were due to a people essentially commercial. The invention of paved roads is traced to the Carthaginians. Rome, ever awake to the advantages to be gained from conquered people, followed in the steps of the Carthaginians, and vastly extended and improved their processes in the construction of roads.

The Via Appia, the Via Aurelia, and the Via Flaminia were the first great monuments of the Roman people in this department of art. Under Julius Cæsar, the capital of the empire was made to communicate with all the chief towns by paved roads; and during the last African war, a road of this kind was constructed from Spain through Gaul to the Alps. After this, these great lines of communication were extended through Savoy, Dauphiné, and Provence; through Germany, and every part of Spain; through Gaul, and even to Constantinople; through Asia, Hungary, Macedonia, and to the mouths of the Danube. Neither did the interposition of seas obstruct the labour or daunt the enterprise of this great people. The lines of communication thus constructed to the shores of the continent of Europe were continued at corresponding points of the neighbouring islands and continents. Sicily, Corsica, Sardinia, England, Africa, and Asia, were accordingly intersected and penetrated by roads, forming the continuation of the great European lines. These gigantic works were not mere paths prepared for the action of the feet of horses and the wheels of carriages, formed upon the natural surface of the ground, but were constructed on principles in some respects as efficient as those which modern engineering has supplied; forests were opened, mountains excavated, hills lowered, valleys filled up, chasms and rivers bestridden by bridges, and marshes drained, to an extent which would bear no mean comparison with the result of great engineering enterprises in recent times.

In India and other countries of the East, roads were formed at an early period; and well-formed roads, with a milestone at the end of every koss, as the native mile is called, were constructed by the Moguls. Such roads connected Agra with Lahore, and Lahore with Cashmere. But after the death of Aurungzebe, these roads fell into decay, and good roads have since been constructed only by the British, who have carried an excellent metalled road, called the Grand Trunk Road,

from Calcutta to Peshawur, on the borders of Affghanistan. The metalling of these Indian roads is for the most part of kunker—a calcareous nodule deposited by the evaporation of the waters of the rivers, and found widely throughout the soil. The kunker is wetted, and is pounded down by beaters into a crust of from nine to twelve inches thick, and it forms a smooth and excellent road. In some localities the kunker is impregnated with iron, and the surface of the road in those places becomes like an iron plate.

English Roads.—The first roads of artificial construction in England, if not formed by the Romans, were at least greatly improved by their labour while it was a Roman province. A grand trunk road was carried through the country north and south, and another nearly at right angles to it east and west. These main lines were supplied with branches, extending in every direction which the conquerors found it expedient to render accessible to their arms. The road called Watling Street led from the southern shore of Kent, by Rutupiæ (Richborough) and London, through St. Albans and Stony Stratford to Caernarvon (Segontium). Ikenild, or Rikenild Street, extended from Tynemouth, through York, Derby, and Birmingham, to St. David's. The Irmin Street led from the latter place to Southampton; the Foss Way from Cornwall to Caithness, or perhaps, more correctly, only to Lincoln. (Lappenberg, *England under the Anglo-Saxon Kings*, i. 61.)

After the withdrawal of the Roman legions, the existing roads seem to have been suffered to fall into decay, while new roads were not constructed. For many centuries, such intercourse as was maintained between the various parts of this country took place almost exclusively by rude paths, capable of being passed on foot, or at best by horses, carried over the natural surface of the ground in straight directions from place to place. It was not till the reign of Charles II. that any attempt was made by the legislature to improve the roads of the country. In the sixteenth year of the reign of that monarch, the first turnpike-road was established by law. It passed through Hertfordshire, Cambridgeshire, and Huntingdonshire. It was not, however, till about a century from the present time, that any great or effectual attempts were made to establish a system of good roads through the country. Till nearly the middle of the last century, most of the goods were conveyed from place to place in Scotland on pack-horses. Oatmeal, coals, turf, and even straw and hay, were conveyed in this way; but in carrying goods between distant places it was necessary to employ a cart, as all that a horse could carry on his back was not sufficient to defray the cost of a long journey. The time usually required by the carriers to perform their journeys seems now almost incredible: the common carrier between Selkirk and Edinburgh, a distance of thirty-eight miles, spent a fortnight in his journey, going and returning. The road, for a considerable extent, lay along the bottom of the district called Gala Water; the bed of the stream, when not flooded, being the tract chosen, as the most level and easiest to travel in.

Nor were the means of travelling between large towns much better. In 1678, a contract was made to establish a coach between Edinburgh and Glasgow, a distance of forty-four miles. This coach was to be drawn by six horses, and the journey between the places, to and from, was engaged to be completed in six days; even so recently as the year 1750, the stage coach from Edinburgh to Glasgow took a day and a half to make the journey; and in the year 1763, there was but one stage coach between Edinburgh and London, which started once a month from each place, and took a fortnight to perform the journey.

It happens that the line of road now occupied by the Liverpool and Manchester Railway and its branches, and travelled daily by thousands of passengers, at a speed of thirty-five miles an hour, including stoppages, was, in the year 1770, travelled over by Mr. Arthur Young, who has left us in his *Tour* the following account of the state of the roads at that time: 'I know not in the whole range of language terms sufficiently expressive to describe this infernal road. Let me most seriously caution all travellers, who may accidentally propose to travel this terrible country, to avoid it as they would the devil; for a thousand to one they break their necks, or their limbs, by overthrows or breakings-down. They will here meet with ruts, which I actually measured four feet deep, and floating with mud only from a wet summer. What, therefore, must it be after a winter? The only mending it receives is tumbling in some loose stones, which serve no other purpose than jolting a carriage in the most intolerable manner. These are not merely opinions, but facts; for I actually passed three carts broken down in these eighteen miles of execrable memory.'

With the exception of a few rare instances of important roads, constructed under special Acts of Parliament, the roads of England have not been constructed on any scientific principle, and are, in most cases, nearly coincident with the foot and horse paths adopted by the early inhabitants of the country. These rude paths, having been formed at an early period, were gradually improved, so as to be capable of being travelled over by wheel carriages. The natural surface of the ground was in time covered with an artificial coating of gravel or stones; hills too steep to be surmounted by carriages were either levelled, and the material obtained from their excavation thrown into the valleys, or the roads were carried round them; at a later period fences were added; and thus, by slow degrees, the old horse path grew into the modern road. How far removed from a truly good and scientific line of communication such a road must be, will be apparent to anyone who considers what

the principles ought to be on which a road should be laid down and constructed.

The Art of Road-making.—When it is proposed to construct a line of road extending between two places, the engineer upon whom such a duty devolves first makes himself well acquainted with the surface of the country lying between the two places, so as to obtain an acquaintance with the face of the country, somewhat approaching to that which would be supplied by a superficial model of it, which would exhibit all its inequalities and undulations of surface. He must then select what he considers, all circumstances being taken into account, the best general route for the proposed road. But, before laying it out with accuracy, it is necessary to make an instrumental survey of the country along the route thus selected; taking the levels from point to point throughout the whole distance, and making borings in all places where excavations are required, to determine the strata through which such cuttings are to be carried, and the requisite inclinations of the slopes or slanting sides, as well of the cuttings as of the embankments to be formed by the material thus obtained. It is also requisite, in the selection of the route for the proposed road, to have regard to the supply of materials, not only for first constructing it, but for maintaining it in repair. Thus, the position of gravel pits and quarries in the neighbourhood of the proposed line, and the modes of access to them, should be well ascertained. The results of such an investigation should be reduced to a plan and section; the plan of the road being on a scale not less than 66 yards to an inch, and the section not less than 30 feet to an inch.

The loss of tractive power, and the danger to travellers produced by steep acclivities, render it especially necessary that a proper limitation should be imposed upon the inclinations or acclivities on every line of road on which much traffic is carried on. As, however, this reduction of hills in a country where much inequality of surface exists is attended with a considerable outlay of capital, the engineer will have to balance the cost of constructing a road having the best possible inclinations against the advantages to be obtained in the permanent working of the road; and if the expected traffic be not such as to yield advantages proportionate to the capital absorbed, greater rates of inclination must be allowed to the hills, with a view to diminish the extent of the works, and to render the expense of constructing the road proportionate to the traffic expected upon it.

The exact course of the road and the degree of its acclivities being determined, the next thing to be considered is the formation of its surface. The qualities which ought to be imparted to it are twofold—first, it should be smooth; secondly, it should be hard: and the goodness of the road will be exactly in the proportion of the degree in which these qualities can be imparted to it, and permanently maintained upon it. An error prevailed among road engineers until a very recent period. It was considered that smoothness of surface alone was sufficient for the perfection of a road; and that, providing it could be made sufficiently durable, it was unimportant how soft or yielding the coating of the road might be. This error, into which, among others, Macadam himself fell, was based upon a neglect of one of the most important circumstances to be considered in the construction of a road. The main object to be attained by all roads is the diminution of the resistance which a carriage opposes to the tractive power. Other things being the same, it was sufficiently apparent that this resistance would be diminished by increasing the smoothness of the road surface. But roughness or unevenness of surface is not the only cause of resistance to the tractive power. If two roads have their surfaces equally smooth and even, but one is soft and elastic, so as to yield under the pressure of the wheel, recovering its form as the wheel advances, and the other is hard and unyielding, the resistance to the tractive power will be greater on the soft and yielding road than on the hard and unyielding road; and this augmentation of resistance will be in proportion to the softness of the surface. That this must be the case, admits of immediate demonstration on mechanical and mathematical principles; but, without resorting to these, it must be sufficiently apparent from the results of the most common experience. A surface of velvet may be as smooth and even as a surface of ice; but if an ivory ball be rolled on the latter, it will continue its motion much longer than on the former. In fact, the wheels of a carriage in passing along a soft road sink into its surface, as the ball would sink into the pile of the velvet; and even if, by virtue of its elasticity, the surface of the road, like that of the velvet, recovered its smoothness after the pressure has been removed from it, still a resistance would be offered to the drawing or impelling power, which would not be produced by a hard and unyielding surface equally smooth.

Macadamisation.—This process, which has received its name from Macadam, to whose labours the improvement of the roads of England within the last half-century owes so much, consists in forming the road crust of stones, broken with a hammer into angular pieces of a small and uniform size. This method, however, is one which was long practised in various parts of Europe. When the stones of which the road crust is to be formed are broken to the proper magnitude and form, they are spread over the surface of the road in a layer of 3 or 4 inches thick. After this has been consolidated by carriages working upon it or by rollers, another layer of broken stones of equal depth is laid upon it; it is consolidated in like manner; and thus one layer is laid over another until an artificial crust is formed of broken stones of sufficient thickness to give the requisite strength to the road.

A coating or road crust thus formed might

be constructed on any substratum whatsoever, and a smooth and apparently good road would be obtained. It was the practice of Mr. Macadam to disregard the nature of the substratum; and he maintained that if it was not such a bog as would not allow a man to walk over it he would even prefer it to a hard bottom.

Telford's System.—The improvement in road-making which consisted in a due attention to the substratum or foundation of the road, so as to give increased facility to the tractive power by rendering its surface hard and unyielding, is due to the late Mr. Telford. The following is a description of the method of constructing such a road practised by that eminent engineer.

Upon the level bed prepared for the road materials, a bottom course or layer of stones is to be set by hand, in form of a close firm pavement. The stones set in the middle of the road should be 7 inches in depth; at 9 feet from the centre the depth should be 5 inches; at 12 feet, 4 inches; and at 15 feet, 3 inches; the entire width of the road being 30 feet. These stones are to be set on their broadest edges lengthwise across the road, and the breadth of the upper edge should not exceed 4 inches. All the irregularities of the upper part of this pavement are to be broken off by hammers, and all the interstices to be filled with stone chips firmly wedged or packed by hand with a light hammer; so that when the pavement is finished, its cross section shall have a convexity of surface of about 4 inches in the centre above the extreme edges: 18 feet in the centre of this pavement are to be coated with a layer of hard broken stones, 6 inches deep; of these 6 inches, 4 must be first put on and worked down by carriages and horses in the ordinary traffic of the road, care being taken constantly to rake in the ruts until the surface has become firm and the crust consolidated. After this, the remaining 2 inches of stone may be put on. The whole of this stone, forming 6 inches of crust, is to consist of pieces broken as nearly as is practicable into a cubical form, and of such a magnitude that they can pass through a ring of 2½ inches internal diameter. The spaces on each side of the middle 18 feet are to be coated with broken stone or well cleansed strong gravel up to the level of the footpath or other boundary of the road, so as to make the whole convexity of the road 6 inches in the middle above the level of the edges; and the whole of the materials thus formed and consolidated should be covered with a coating 1½ inch deep of good gravel free from clay or earth.

Such was the method practised by Mr. Telford in the construction of great main roads, such as that between Holyhead and Shrewsbury. In the streets of towns, and other places where roads have to bear a still heavier traffic, such a road as that above described is found to be subject to a superficial wear, so rapid as to produce an intolerable quantity of dust in summer and of mud in winter. In such places recourse has been generally had to pavement. The first object to be secured for a durable pavement, as well as in other roads, is to secure a good foundation. The best method is to lay a foundation of concrete, the bed of which should be formed with a convexity sloping to each side by a fall of about 1 in 50. On this foundation, when sufficiently consolidated, a pavement formed of blocks of stone is laid, the blocks being 10 inches in depth, from 10 to 15 inches in length, and from 6 to 8 inches in width. Such is the structure which is requisite for the streets which are the main thoroughfares of a great city; a pavement with less strength of foundation, and formed of smaller blocks of stone, being used for the streets of less intercourse.

The many inconveniences produced in the great thoroughfares of London, by the rapid wear of every kind of pavement hitherto adopted, by the suspension of intercourse during the frequent repairs, by the dust in summer and the mud in winter produced by a surface of broken stones, and the intolerable noise caused by every species of stone pavement, led to much enquiry as to the possibility of constructing some road with sufficient strength and durability, and presenting a surface which, while it would be free from the noise of a stone pavement, would not be attended with the inconvenience of dust and mud produced by a surface of broken stone. This problem was supposed to be in a great degree solved by the adoption of a pavement of wood. A short piece of Oxford Street was thus paved in the beginning of 1839. After a trial of several months, the same pavement was extended nearly throughout the whole extent of that street; and this method was adopted in several other thoroughfares of London. In the northern parts of Germany and in Russia such pavements have been long in use; and some of the main streets of Petersburg and Vienna have long been paved in this manner. Various methods were adopted for laying the wood pavements of London; but though every process that ingenuity could devise was attempted, none of them have been found to enable it to withstand the heavy traffic to which it was then subjected, and for such purposes wood pavement has been discarded. More recently iron pavement, consisting of perforated plates or plates with prominent projections for the horses' feet, have been tried with very moderate success, and up to the present time the best paving material is undoubtedly granite. Much might be done for the improvement of our pavements if subways were carried through all our streets, in which the gas and water companies might be compelled to lay their pipes; if vehicles were divided into low speed and high speed, each with its proper track; and if some uniformity of breadth in each class of vehicle were enforced. It would then become practicable to lay down plate tramways of iron, on which the wheels would travel with a diminished traction and a diminished noise, while the middle portion of such way, on which the

horses' feet acted, could be laid with granite pavement as at present. It will, however, be impossible much longer to accommodate the traffic of London without the construction overhead of two tiers of railway streets, crossing one another at different levels.

For further details on the subject of roads generally, the reader is referred to Sir Henry Parnell's *Treatise on Roads*. See also the *Encyclopédie*, article 'Chemin;' Bergier, *Histoire des Grands Chemins de l'Empire Romain*; *Annales des Ponts et Chaussées*; Anderson's *Commerce*; M'Culloch's 'Treatise on Commerce,' *Library of Useful Knowledge*; Mr. Telford's *Reports*.

Roasting. In Chemical Metallurgy, the protracted application of heat to metallic ores, below their fusing points. It is generally resorted to to expel volatile matters, especially sulphur, arsenic, carbonic acid, water, &c., and is generally performed in a current of air, so as to effect simultaneous oxidation.

Rob. A term of Arabic origin, applied by old pharmaceutical and modern French writers to thin extracts or inspissated juices.

Robbery (Ger. rauben, Lat. rapio, *to rob*). In Law, a felonious taking of money or goods of any value from the person of another, or in his presence, against his will, by violence or by putting him in fear: and this, whether the fear be of injury to the person's property or character. But it is necessary that the fear be of immediate injury, not of some future injurious results; and then the money must, generally speaking, be taken immediately upon the threat made, and not afterwards given from fear of consequences. But the *extortion* of money by threat to accuse of an infamous crime was made robbery by 7 & 8 Geo. IV. c. 29. The law on the subject is now collected in the recent statutes 24 & 25 Vict. c. 44, c. 96. Robbery, if accompanied by wounding, was a capital felony until the passing of the last-mentioned statute, but is not now in any case punishable by death.

Roberval's Balance. [Balance of Roberval.]

Robes, Master of the. An officer in the royal household. [Household.]

Robinia (after Jean Robin, a French botanist). A genus of *Leguminosæ*, restricted to a few North American trees and shrubs, commonly called Acacias in this country. Some, as *R. hispida*, are ornamental flowering shrubs; but the most important is *R. Pseud-Acacia*, the Locust-tree or False Acacia, which grows from fifty to eighty feet high, and yields a hard timber, much employed in the United States for posts, pales, and similar purposes, and also by carpenters and cabinet-makers, and to a more limited extent by shipwrights. It is, however, seldom of sufficient size to afford planks suitable for shipbuilding, its principal use being for the manufacture of treenails, for which it is admirably adapted; and considerable quantities of these locust treenails are exported to this and other European countries. It is also cultivated in the South of France, for vine-props. The timber is of a yellowish colour, more or less tinged with reddish-brown in the centre. The roots have the taste and smell of liquorice, but are a dangerous poison, and accidents have occurred from their being mistaken for liquorice-roots.

Roc or **Rukh.** A monstrous bird of Arabian mythology, of the same fabulous species with the simurg of the Persians. In the notes to vol. iii. of Mr. Lane's edition of the *Arabian Nights' Entertainments* are some curious extracts from writers of old voyages, designed to show that the tale was founded on the wonderful accounts of travellers, and that even Sinbad's well-known adventure, when his crew broke the roc's egg, and were attacked in consequence by the enraged pair of birds, is borrowed from the serious narration of Ibn-el-Wardee. The roc is also described by Marco Polo. (Marsden's transl. p. 707.) In a drawing from an illuminated Persian MS., which Mr. Lane has copied, the roc, or rather simurg, which is represented as carrying off three elephants in its beak and claws, is something like a cock, with eagle's wings and an extravagant tail. The simurg is a creature of Persian mythology: it is the phœnix of Oriental fable, one only living at a time, and is said to attain the age of 1,700 years. (See the notes to Southey's *Thalaba*.)

Roccella. [Orchella Weed.]

Roccellic Acid. An acid obtained from the *Roccella tinctoria*.

Roche Alum. Alum deprived of part of its water of crystallisation by heat. The term is also sometimes applied to the so-called *Roman Alum*, made from the alum ore of the Solfaterra, near Naples.

Rochelle Salt. The tartrate of soda and potassa. It is a double salt, composed of 2 atoms of tartaric acid, 1 of potassa, and 1 of soda. Its crystals, which are large and well-defined prisms, often presenting eight, ten, or twelve sides, include 8 atoms of water.

Rochet (Fr.; Ital. rochetto). A linen garment worn by bishops under the chimere. It was the ordinary dress during the middle ages, but the word itself cannot apparently be traced back beyond the thirteenth century. (Hook, *Church Dictionary*.)

Rock Butter. [Petroleum.]

Rock Cork. A variety of Asbestos. [Mountain Cork.]

Rock Crystal. A common Mineralogical term applied to transparent crystallised silica: it is also called *Quartz*. Fine specimens in this country are found in Cornwall and Devonshire, at Clifton, Gloucestershire (*Bristol Diamonds*); in Cumberland; near Cairngorm; at the Mourne mountains of Ireland (*Irish Diamonds*), and at Finglen mountain, close to Dungiven. [Cairngorm; Dungiven Crystals.]

Rock Leather. [Mountain Leather.]

Rock Marrow. [Lithomarge.]

Rock Oil. [Petroleum; Seneca Oil.]

Rock Salt. Common salt or chloride of sodium, composed of 60·4 per cent. of chlorine and 39·6 sodium. It occurs in cubical crystals, and in large beds and masses, in the waters of the sea, as well as in those of certain springs and lakes. The geological position of Rock Salt is very various, but the great British deposits of this substance in Cheshire and Worcestershire are found in the New Red Sandstone. The principal salt-works in England are at Northwich, Middlewich, and Nantwich in Cheshire; at Droitwich in Staffordshire; Stoke Prior, Worcestershire; in Durham; and in Ireland at Carrickfergus near Belfast.

Rock Shells. The common name of certain Univalves, characterised by the long straight canal which terminates the mouth of their shells. [Murex.]

Rock Soap. A hydrated silicate of alumina resembling Bole, and used for crayons and for washing cloth. It is found in basalt in Skye, and in greenish-grey or brown modules in the trap rocks of Antrim.

Rock Wood. The common name for ligniform Asbestos. It is chiefly found at Sterzing in the Tyrol.

Rocks (Fr. roc, roche, Ital. rocca). All mineral masses underlying the soil and subsoil of any part of the earth are designated by the geologist *rocks*. The term has long been in use, and is convenient.

Rocks are either fossiliferous or non-fossiliferous, the former being for the most part stratified and of aqueous origin, and the latter frequently unstratified. Of the latter some appear to have distinct reference to the action of heat or have been apparently so far altered as to be with manifest reason called igneous or crystalline. Among the former are lavas and basaltic rocks, among the latter granites and porphyries. There is a large intermediate class called metamorphic, including slates and schists.

The essential basis of stratified rocks is always either limestone, sandstone, or clay. Unstratified rocks present modifications of the same materials. Stratified rocks often contain numerous organic remains, which are rarely found in unstratified rocks.

Rocks present many mechanical modifications, resulting from the conditions to which they have been exposed.

The general classification of rocks will be found described in the article on Descriptive Geology; the details of the rocks themselves and their mechanical displacements are noticed under various heads. [Geology.]

Rocks, Structure of. Rocks exhibit a structure not less distinct and peculiar than simple minerals. The details of structure are, however, different in the two cases. The essential points of structure may be distinguished as either *concretionary*, *prismatic*, *laminated*, or *porphyritic*.

Similar mineral matter, dispersed irregularly through rocks, has a tendency to separate into bands consisting of spheroidal or flattened concretions with concentric arrangement. The structure thus induced is called *concretionary*. Many varieties of limestone, nodules of carbonate of iron in the coal measures, and the curious concretions in clay called Septaria, are of this kind.

Concretionary structure tending to produce spheroidal masses, when carried to such an extent that the whole rock is subject to it, becomes *prismatic*. It is well exemplified in the columnar basalt of Fingal's Cave and Staffa. [Basalt.] Prismatic structure extends into almost all hard rocks, producing the tendency to split in certain directions rather than others. Granite especially shows it; but limestones, when crystalline, are not less affected.

Laminated structure includes Stratification, Cleavage, and Foliation, each of which is noticed in a separate article.

Porphyritic structure is that of crystals embedded in a base, and is also noticed in the articles on Granite and Porphyry.

Rocket (Ger. rackete, Ital. raggetto, from Lat. radius, *a ray*). In Artillery, a cylindrical case of paper or metal, containing inflammable composition. To one end of the case is attached a head usually conical or cylindro-conoidal; the other end is closed, but has one or more vents for the escape of the gas from the ignited composition. A conical cavity is left in the rocket, its base coinciding with that of the rocket; by this means a large surface of composition is ignited at once, and so great a quantity of gas is generated that it cannot escape from the vent as quickly as formed, and therefore it exerts a pressure in every direction inside the rocket. The pressures on the sides balance each other, but that on the head is greater than that on the base, from the escape of gas through the vents. This excess of pressure imparts motion to the rocket in the direction of the head, and continues to do so until the composition is all consumed. A stick or long rod is attached to the rocket, to counteract, by the resistance of the air upon it, any tendency to rotation round the shorter axis.

The war rockets at present in our service were invented by Sir William Congreve; their heads contain powder, and can be made to act as shells. They are fired from tubes raised above the ground. Signal rockets contain star composition in their heads, and are fired vertically.

It has been found impossible to obtain any accuracy of fire with Congreve rockets, and so they can be used only against objects covering much ground. Mr. Hale has introduced a rocket, giving much greater accuracy of fire, to which a rotation round its longer axis is communicated by the action of the gas issuing from the vents on flanges outside them.

Rockets have been defined as 'ammunition without ordnance, the soul of artillery without the body.' They were probably used in China long before gunpowder was employed to propel shot; and we find them in Italy in 1397, under the name of *rochettæ*.

Sky-rockets are much used in displays of fireworks; a large number, technically called a *bouquet*, being often discharged simultaneously. For this purpose the heads are generally filled with various compositions, producing stars or balls of different colours. Upon the bursting of the head, which occurs when all the rocket composition is consumed, these are ignited and descend in a brilliant shower.

Rocking Stones. [LOGAN STONES.]

Rockwork. In Architecture, masonry wrought in imitation of rough stone, in various arrangements, and used chiefly in the basements of houses, or in such situations as require the effect of solidity and massiveness.

ROCKWORK. In Gardening, this term is applied to a quantity of stones, fragments of rock, or even vitrified bricks, piled together in such a manner as to form a nidus for the growth and display of alpine plants. The materials are sometimes covered with a grouting of cement. When the pieces of rock are of such forms as can be connected together so as to present the appearance of stratification, that mode of arranging them may be adopted; and the soil and plants may be placed in vertical, oblique, or horizontal fissures, or on ledges, according to the lines of stratification. When, however, as is most frequently the case, land or water-worn stones are used, they may be distributed over a mound of earth, not uniformly, but in groups, with smooth surfaces of soil between, as where stones of different sizes are seen cropping out of the surface of a green hill or hillock. When agglutinated masses of vitrified bricks are used, either alone or mixed with land stones of different sizes, they may be distributed over a mound, or along a bank of soil, in such a manner as to produce a varied surface, without attempting to imitate nature, and with interstices between them for inserting the plants. Imitations of conical hills, caverns, precipices, and even the Alps, on a small scale, have been made in rockwork; but these, and all other imitations of nature, require to be designed and directed by the eye and mind of an artist. In general the piles of stone called rockwork, in gardens, might with more propriety be called heaps of stones.

Rocky Mountains. These mountains consist of two parallel ranges, occasionally united, and extending from the plateau north of Mexico, nearly parallel to the west coast of North America, to the Arctic Ocean. Both ranges are comparatively low at first, but rise into groups of very lofty mountains, frequently above the snow line as they advance northward. The range generally is barren and desolate, but the valleys between the mountains are long, narrow, and rich.

The length of range of the Rocky Mountains is nearly 18,000 miles, but the width is not very great. The chief elevations (ranging to nearly 16,000 feet) occur between the fiftieth and sixtieth parallel, though some lofty mountains are as low down as latitude 40° N. Most parts of the chain are as much as 300 miles from the coast.

The principal sources of the great rivers of North America, with the exception of the St. Lawrence, are to be found in the valleys on the eastern side of the Rocky Mountains; and the gold deposits of California and Oregon occur in the valleys between the mountains of this chain and the subordinate coast range.

Rococo. The name given by the modern French architects to anything ancient and out of fashion; but it has been especially applied by them to those tormented decorations of the period of Louis XIV. and Louis XV. which have become as much the objects of horror to the architects of the present day, as they were once the fashion. Interrupted pediments, columns made stouter at the top than they are at the bottom, broken curves and ornaments, tortured in every shape and style, constitute the picturesque but illogical style generally known as the *rococo*. The English never adopted this style except in their furniture.

Rod (Dan. rode, Dutch roede). A measure of length, otherwise called a *pole*. It is $5\frac{1}{2}$ yards, or $16\frac{1}{2}$ feet; and four of these make the *Gunter's chain*.

Rodents (Lat. rodo, *I gnaw*). The name given by Cuvier to the *Glires* of Linnæus, an order of Lissencephalous Mammals, comprehending those which have two long chisel-shaped incisors in each jaw, and no canines, but a vacant interspace between the incisors and the molars. The lower jaw is articulated by a longitudinal condyle, in such a way as to allow of no horizontal motion, except from back to front, and vice versâ, as is requisite for the action of gnawing. The molars also have flat crowns, whose enamelled eminences are always transverse, so as to be in opposition to the horizontal motion of the jaw, and to increase the power of trituration. The genera in which these eminences are simple lines and the crown is very flat, are more exclusively frugivorous; those in which the eminences of the teeth are divided into blunt tubercles are omnivorous; while the small number of such as have no points more readily attack other animals, and approximate somewhat to the Carnaria. The form of the body in the Rodentia is generally such that the hinder parts of it exceed those of the front, so that they rather leap than walk. In some of them this disproportion is even as excessive as it is in the kangaroos. In the whole of this class the brain is almost smooth, and without furrows; the orbits are not separated from the temporal fossæ, which have but little depth; and the eyes are altogether lateral. The inferiority of these animals is visible in most of the details of their organisation. Those genera, however, which possess stronger clavicles have a certain degree of dexterity, and use their fore feet to convey their food to the mouth.

Rodomontade. A term that has passed into most European languages; from Rodomont,

a boisterous character in the *Orlando Furioso.* The name is probably a corruption of RHADAMANTHUS.

Roe (Ger. rogen, meaning originally *fruit*). The ova of osseous fishes which are developed simultaneously and in great numbers are so called.

Roesslerite. The name given by R. Blum to a newly discovered hydrated arseniate of Magnesia, from the Kupferschiefer of Bieber.

Roestone. A granular limestone, or oolite.

Rogations (Lat. rogatio, from rogo, *I ask*). In the Ritual, public supplications or litanies were anciently so termed, until the latter designation began to supersede every other. (Palmer, *Orig. Liturgicæ*, vol. i. p. 270.) In the Ecclesiastical Calendar, the three Rogation days are the Monday, Tuesday, and Wednesday next before Ascension-day.

Rogue's Yarn. A yarn of a different twist and colour from the rest, and inserted in the royal cordage, to identify it in case of theft.

Rohitas (Sansc.). In the Veda, the rays of the sun are called by this name, which, like that of the CHARITES, was originally a mere adjective signifying *brown*, but came at length to signify some special animal of that colour. Thus the white horses of the sun were called the *Arushîs.* [EROS; SIGURDR.]

Roland. In the cycle of the Carolingian myths, a Paladin of Charlemagne, who fell at the battle of Roncesvalles. The memory of this battle is preserved in the spirited Basque song of Attabiscar, which M. Francisque Michel (*Le Pays Basque*, p. 235) ascribes to the age of which it speaks. (*Edinburgh Review*, April 1864, p. 383.) This fight is also mentioned by Eginhard in his *Life of Charles the Great*, c. ix., and from this writer we receive the name of a Roland (Hruodlandus, Britannici limitis præfectus), who was there slain. This Roland, whose whole authentic history is contained in this solitary notice, is supposed by some to be the Roland of the epic cycle; and thus the fact mentioned by Eginhard is regarded as the historical substratum underlying the legend, and perhaps giving rise to it. This circumstance has led Mr. Freeman (*Fortnightly Review*, No. xxiv. May 1, 1866) to classify myths as quasi-historical and quasi-theological, the tales of Zeus, Dêmêtêr, and Heracles belonging to the latter class, those of the Trojan war and the Carolingian epic to the other. From the supposed conclusion that the notice of Eginhard proves Roland to have been a real man, Mr. Freeman gathers that his famous legendary death is a very easy perversion of his historical death; and he thus expects to find about the same amount of truth in the legend of the Trojan war which he finds in the Carolingian myths. In reply to this it has been asserted that the truth, if found at all, is obtained, not from the legend, but from the contemporary notice of Eginhard, without which the myth would for all historical purposes be absolutely worthless; and that without similar contemporary notices of persons named in the Homeric poems the tale of Troy is destitute of all historical value, and that, therefore, while the existence of such persons cannot be denied, so neither can it be affirmed. The danger of theorising from the mere occurrence of names is further pointed out in the article SIGURDR, where it is shown not only that the names of persons who lived in the fourth and succeeding centuries are introduced into the *Nibelungen Lied*, but that the fortunes ascribed to the persons so named agree singularly with their actual fortunes as known to us from contemporary historical documents, while these names and the adventures assigned to them are merely modifications of names and incidents found in the far earlier *Volsunga Saga.*

Rolle's Theorem. In the *Theory of Equations*, this theorem establishes the following important relation between the roots of an equation $F(x)=0$, and of the roots of the derived equation $F'(x)=0$, where $F'(x)$ is the first derived function of $F(x)$. *Between each pair of real roots of an equation occurs at least one real root of the first derived equation.* From this theorem it follows that: 1. The primitive equation cannot have more than one real root between any pair of adjacent roots of the first derived equation. 2. It cannot have more than one root greater than the greatest root of the derived equation, nor more than one root less than the least. 3. The primitive having m real roots, the first derived equation will certainly have $m-1$, and the r^{th} derived equation will have at least $m-r$ real roots. 4. The primitive will have at least as many imaginary roots as any one of its derivatives.

Rolle was a French mathematician of the seventeenth century. His treatise on Algebra was published in 1690.

Roller. In Printing, a cylinder of wood coated with a composition of treacle and glue, and revolving upon an iron rod running through it, with which to ink the form of type previous to taking an impression. The introduction of composition rollers in place of pelt balls has been the cause of a complete change in printing. But for this invention, machine or cylindrical printing could never have been accomplished, as all the early attempts with sheepskins failed, from the necessity of joining the edges.

Rollers. In the service of ordnance, cylinders of wood, used in mounting guns on their carriages, shifting them from one carriage to another, or moving them on the ground.

ROLLERS. In Ornithology, a family of birds (*Coraciadæ*) of the order *Volitores*, of which there is one European species, *Coracias garrula*, of a vivid sea-green colour with some purple and red marks, about the size of a jay: they have a great and varied power of flight, and are chiefly insectivorous.

ROLLERS. On Shipboard, certain cylindrical pieces of timber placed so as to revolve horizontally or vertically. Their object is to lessen the friction on the hawsers in passing any angle.

Rollers. The name given by seamen to unusually heavy waves, which set in upon a coast or island without wind. They are frequent at the island of Ascension.

Rolling. In Mechanics, this term is used when all the parts of the surface of one body come into successive contact with those of another, under such conditions that at every instant the portion of the two surfaces which *have been* in contact are exactly equal. When this condition is not fulfilled, the one surface is said to slide upon the other. The friction of bodies in rolling is much less than in that of sliding; and hence the advantage of wheels to all kinds of carriages. [Friction.]

Rolling. In Naval language, the lateral oscillation of a vessel. This motion, which is often very great when the vessel is running before the sea, endangers the masts, strains the sides, and loosens the decks at the waterways; it also tends to cause the guns to break adrift. When the centre of gravity is too low, the oscillations begin and end violently. The changes in the stowage necessary to modify the nature or extent of the roll are made by seamen from experimental knowledge.

Rolling is, in fact, an oscillation or partial revolution round the centre of gravity of the ship. Of course if the centre of gravity be too high up, the vessel's tendency will be to capsize: but on the other hand, if it be far below the load-water-line, there remains so little depth of vessel and keel for the water's resistance to operate on, in opposition to the height of hull and masts above the centre of gravity, that the rolling will necessarily be violent and considerable. The least rolling is experienced when the centre of gravity coincides nearest with the load-water-line.

Rolling Curves. [Roulette.]

Rolling Mills. In Mechanics, massive rollers connected by toothed pinions and put in motion by a steam engine, for the purpose of rolling out metal into bars or plates. Such mills are most used for rolling iron, though used also for rolling copper, silver, and other metals into thin sheets. The rollers are fixed in massive framing, which has to support a prodigious strain; for rolling bars they are grooved, but for rolling plates they are plain. In rolling iron the *bloom*, as the mass of heated metal is called, is drawn in, and compressed and elongated in passing through. The bar so formed is passed through a succession of similar grooves, decreasing in size till it is reduced to about four inches in width, from three-quarters of an inch to an inch in thickness, and from ten to twelve feet in length. In this state if the bloom has been taken from the puddling furnace it is termed *puddle bar*. The bars are then cut into pieces, piled, heated, &c., and a second time rolled. The bars produced by this second process are called *merchant bars*; or the bloom may be rolled into plates. The trains of rollers used in iron-works are distinguished by several special names. Thus the first pair employed in working the rough or puddled bars, are known as the *forge train*, *blooming mill*, or *puddle-bar train*, the term *train* in all cases meaning a series of two or more pairs of rolls connected together and worked as one system. The trains used in producing finished iron are known as *merchant-bar*, *plate*, *rail*, and *wire mills*, according to the section produced. The first pair of rolls in a train is known as the *roughing-down*, and the last as the *finishing* rolls.

In rolling heavy masses of iron, such as boiler or armour plates, where the pile or bloom cannot be lifted back over the top of the mill, the rolls must be reversed after each passage, and the pile is passed backwards and forwards alternately; on this plan it is, however, impossible to work with any speed. One arrangement to obviate the necessity of reversal is the *three high train*, in which three rollers are placed vertically above each other in the same housings, so that the middle roll moves above its centre in the same direction as the upper one, and below the centre as the lower one, forming a complete double pair moving in opposite directions, so that the iron may be passed backwards and forwards without reversing the motion of the driving power. The universal rolling mill is a combination of a vertical pair of rolls with the ordinary horizontal pair, so that a pile may be welded by pressure on all sides at the first heat without burning.

The *slitting mill* is a kind of rotatory shears used in cutting up bars of iron into nail rods.

The horizontal, non-condensing steam engine, from its compact form and convenience of handling, is well adapted for giving motion to the machinery of iron works. It is cheaper in its original cost, and all its parts being fixed upon a large bed plate, it needs a comparatively small amount of masonry to render it solid and secure. But whatever form of engine may be employed, it is indispensable to the efficiency of the mechanism that a very large and swift fly-wheel shall be introduced, which will absorb power when there is no iron passing through the mill, and give power out when the mill is labouring under a heavy charge. The fly-wheel attached to the engine set up at Millwall by Boulton and Watt for rolling armour plates weighs 100 tons.

Rolling Pendulum. A cylinder caused to oscillate in small spaces on a horizontal plane. Its mathematical expressions are interesting, but it has been applied to no important practical purpose.

Rolling Tackle. A tackle or pulley hooked to the weather quarter of a yard, and to a lashing or strap round the mast near the slings or parral of the yard; the object of it is to keep the yard constantly over to leeward, thereby depriving it of play and friction when the ship rolls to windward.

Rolls of Court. The archives of a manor, in which are recorded the surrenders and admittances of tenants and the other business done at the manorial courts, &c.

Rolls, Master of the. A high officer of the Court of Chancery, second only to the lord chancellor. He is appointed by the crown by letters patent, and holds his office for life. The Master of the Rolls administers justice in a separate court. He has the power of hearing and determining originally the same matters as the lord chancellor, excepting cases of lunacy and bankruptcy; but all orders and decrees pronounced by the Master of the Rolls must be signed by the lord chancellor before they are enrolled. The Master of the Rolls is the keeper of all the records of the Court of Chancery after the decrees and orders have been enrolled; and on that account he was anciently styled *guardien des rolles*. The Master of the Rolls ranks immediately after the Chief Justice of the Queen's Bench: his salary is 6,000*l.* a year.

The Master of the Rolls formerly held his sittings only in the evening, and until the year 1833 he did not hear motions, pleas, or demurrers; and whatever was presented for his decision, other than the hearing of causes, was brought before him by petition. In the year 1833, however, this was altered; and motions, pleas, and demurrers are now heard by him in the same manner as by the other equity judges. By the Act 1 & 2 Vict. c. 94, entitled 'An Act for the better Custody of the Public Records,' the Master of the Rolls for the time being is intrusted with the custody both of the public records and those of the common law courts and the Court of Exchequer.

Rollster. [ROSTER.]

Romaic. This name is sometimes applied to the language of the modern Greeks, who call themselves Romans, an appellation which has survived the overthrow of the Roman Empire of the East established at Constantinople.

The language differs from the ancient Greek chiefly by the abbreviation of words, indifference to the old inflexions, and the infusion of foreign words and expressions. But a distinction must be drawn between the modern Greek of newspapers and literary writers like Tricoupes, whose language is readily intelligible to all who are acquainted with old Greek, and the more remote popular dialects, which are practically a different language. (Hallam, *Literary History*, part i. ch. ii. § 13.)

Roman Alum. An alum extracted from the volcanic rocks of the Solfaterra near Naples; it crystallises in opaque tubes, and contains more alumina than the common octahedral alum.

Roman Architecture. [ARCHITECTURE.]

Roman Catholics, Romanists, or Papists. Names applied to the members of the church which regards the bishop or pope of Rome as its spiritual head, and asserts an exclusive claim to the title Catholic or universal. [MASS; PAPACY; PENANCE; PURGATORY; TRANSUBSTANTIATION; &c.]

The Roman doctors hold that the Scripture is not sufficient for its own interpretation. The books which compose the canon of the New Testament are, they conceive, desultory and incomplete; being many of them written for special occasions, at a period considerably later than the foundation of the religion in various districts, in some of which whole generations of believers may have passed away without having seen or heard of their contents. It is not to be supposed, however, that doctrines so important as those shadowed forth in the Epistles of St. Paul, or the Gospel of St. John, could have been left untaught to the churches which flourished before their publication or beyond their reach. It must be admitted, therefore, they argue, that the first preachers of Christianity must have been commissioned and instructed to deliver these same doctrines orally; and it is affirmed that several important doctrines are imperfectly developed in Scripture, and would not be understood, except for some such illustration by the way, the result of which is conveyed in the creeds of the first centuries. It is also affirmed that the practice of the primitive church, the infallibility of which is assumed, authenticates various articles of Roman belief, of which only very slight hints are to be found in Scripture, and such, perhaps, as would not have been discovered but for this very evidence of early usage. This line of argument is admitted also by many Protestants, the facts alleged being disputed, and opposite results being thus obtained. It must be allowed, however, that Roman Catholics do not advance any article of belief without pointing out some supposed ground for it in Scripture, although the only proof of this kind is in some cases to be found in writings which Protestants esteem apocryphal. But while Protestants may refer to the practice of the primitive church, and to the traditions which must have circulated in those ages, as genuine historical evidence of the theology of the earliest times, they find too much contradiction in the individual witnesses to consider any one system *deduced therefrom* as infallibly right. The Roman theologians, on the contrary, attaching more importance to this kind of evidence, and labouring under the same difficulty with Protestants in discriminating between genuine and corrupt traditions, take refuge in the position that the pope, as the vicar of Christ, is the authorised interpreter of tradition, and maintain that the dogmas which have been advanced from this source have always been those of the Catholic church, and always authentic. In later times, however, a question has been much agitated respecting the relative authority of popes and councils. The superiority of each has been maintained by different classes of theologians, and it is certain that in some cases the decisions of popes have been ultimately reversed by councils. It is now commonly supposed, by those who judge from the general appearance of things in the theological world, that the theory which ascribes infallibility to the pope alone is gaining ground over the theory so strongly urged in the days when *Cismontane* or *Gallican* opinions prevailed,

namely, that it was to be found only in the decrees of the pope in council; and the assumption of authority by the present pope, in fixing the dogma of the Immaculate Conception, is said to give countenance to those who hold that *Ultramontanism* is for the time prevalent. In a broad sense, the term *Roman Catholics* comprehends certain communions which have become subject by their voluntary act to papal jurisdiction, although retaining some rites and practices of their own, of which the *United Greek Church* is the principal.

Roman Order. [COMPOSITE ORDER.]

Roman School. This school of painting, which, like the Florentine, addressed itself to the mind, is formed upon antique models, and is chiefly distinguished for form and expression. Its style was poetical; embellished with all the grandeur, pathos, and freedom from common matters, that the happiest imagination could conceive. In touch its masters were easy, correct in drawing, learned and full of grace. The heads of the figures are always drawn with great respect to truth and expression, and it exhibits great intelligence in contrasting attitudes. The colouring displays the greatest marks of negligence in this school, which in draperies is eminently successful. At the head of this school was Raphael; and among its other principal masters were Giulio Romano, Perino del Vaga, Michael Angelo da Caravaggio, Barocci, Andrea Sacchi (perhaps the best colourist of thi school), and Carlo Maratti. [PAINTING.]

Roman Vitriol. Sulphate of copper, or blue vitriol.

Romance (Fr. roman, Ital. romanzo). In Literature, a work of fiction in prose or verse, containing the relation of a series of adventures either marvellous or probable. A tale confined to the latter class of events has, indeed, been considered to be more strictly designated by the term *novel*. [NOVEL.] But as our nomenclature for works of fiction is not very precise or accurate, the name *romance* is very frequently used to comprehend both.

The term *romance* is derived from the class of languages in which such fictitious narratives, in modern times, were first widely known and circulated. These were the tongues derived from the Latin, viz. Italian, Spanish, French, which were all Roman dialects, in contradistinction to the European languages of Teutonic origin. But the *langue Romane* more properly signifies the dialect of Southern France, Catalonia, &c., of which the Provençal was a variety.

The famous *Milesian Tales* of antiquity are thought to have been, in classical times, the class of writings nearest approaching to our modern romances. All the original Greek compositions of this kind have perished. But we have, in the *Golden Ass* of Appuleius, a Latin imitation of these, written in the later times of the Roman empire. [PSYCHE; VENUS.] It contains a series of wonderful adventures, sorceries, transformations, love, religion, &c.; and although it has been asserted that the romance, in its proper sense, was unknown to the ancients, it would be difficult to say in what respect, except the total absence of chivalrous sentiment, which is of modern growth, this curious fragment differs from those later inventions which we have agreed to call by that name.

The same may be said, and with even greater strictness, of the Greek pastoral romances; a class of works appertaining to a later period, of which the famous *Daphnis and Chloe* of Longus is the first known specimen. They contain narratives of amours, adventures, &c., usually intermixed with some supernatural interference; and they have the great characteristic of a modern novel—a pair of lovers, by way of hero and heroine, whose attachment is generally brought to a happy termination.

The earliest modern romances were collections of chivalrous adventures, founded chiefly on the lives and achievements of the warlike adherents of two sovereigns, one of whom, perhaps, had only a fabulous existence, while the annals of the other have given rise to a wonderful series of myths—Arthur and Charlemagne. These romances were metrical compositions in that branch of the modern French language termed the *langue d'oil*, which prevailed throughout the north of France, and especially in Normandy. Besides these, a great variety of smaller tales, some chivalrous, some marvellous, some simply ludicrous, termed *fabliaux*, exist in the same language. The date of these compositions extends from the twelfth to the fifteenth centuries.

From the hands of these rhymers the tales of chivalry passed first into those of prose compilers, who reduced them into a form more resembling that of our modern romances. The French prose romances of chivalry, still confined to the same classes of subjects, belong to the fourteenth and fifteenth centuries. These, again, gave birth in two different countries to two widely differing series of works of imagination. In Italy, the poets termed Romanzieri, taking the adventures of the knights of Charlemagne as their subject, transferred the rude conceptions of their predecessors into one of the most finished and enchanting forms of poetry to which modern fancy has given birth. Boiardo, in the latter half of the fifteenth century, was the first of these poets; and the names of Pulci, Ariosto, and Tasso, three of the greatest in Italian literature, grace their long catalogue. In Spain and Portugal a new class of chivalrous romances was called into existence. Lobeira, a Portuguese, in the fourteenth century, composed the first four books of *Amadis de Gaul*. This famous work resembles in character the French romances of chivalry; but narrates the exploits of a new and entirely imaginary hero. *Amadis* was finished, and a long list of similar romances added to it, by subsequent Spanish and Portuguese writers. In these, while adventures became more and more marvellous, the fanciful spirit of chivalry was more and more carried into wild exaggeration. They became, however, so popular as to be transplanted into most

European languages, and even in France to supersede the heroic tales of Arthur and Charlemagne. They declined with the advance of a better taste in literature after the art of printing had been for some time introduced; and were finally driven out of fashion by the wit of Cervantes, whose *Don Quixote* is aimed in great measure against them.

Meanwhile, a new species of fiction had acquired vogue in Italy, to which the term *novel* was first applied. This was the amorous or humorous tale; of which the *Decameron* of Boccaccio contains the earliest and by far the most popular collection. The stories were derived from many originals; but especially from the *fabliaux*, of which mention has been already made. The Italian Novellieri are extremely numerous; but their compositions are always short, and would, in our modern language, be designated by the term *tale*, rather than *novel* or *romance*. They flourished in the fifteenth and sixteenth centuries. From these, again, was derived the comic satirical tale of Spain; a more sustained and longer class of composition, of which *Lazarillo de Tormes* and *Gusman d'Alfarache* are the best known specimens. But in these, which were also caricatures of the chivalrous romances, a long course of independent exploits of the hero formed the substance of the work, and not a story possessing an individual point and interest.

Don Quixote, of which the first part was published in 1609, was the joint result of the romances of chivalry, which it was intended to ridicule, and of the romances of low life, of whose character it contains a large intermixture. Although Cervantes had in view rather the satirical object of his writing than the direct delineation of manners and occurrences, such as we now expect in a novel, yet it may be fairly said that his immortal work is the first of its kind in which human nature is brought on the stage alike unadorned and undegraded; neither exaggerated by the ridiculous costume of chivalry, nor lowered by the familiar buffoonery of a comic tale. While, therefore, it has been the source of numerous imitations in its satirical character, its wide popularity has produced much more lasting effects in another manner: it gave the first example of a work of fiction in which the grave and gay events of life might be mingled together, and in which, also, the views and sentiments of the author might be conveyed through the medium of fictitious personages and events.

On the other hand, the chivalrous romance had been seized, at an earlier period, by a very different genius from that of Cervantes, and applied to another object. The fictions of Rabelais (the *Histories of Gargantua and Pantagruel*) cannot be termed romances; but their popularity was so great that France was inundated for more than a century afterwards with Rabelaisian tales; and many of the elements of the modern low romance, such as comic hyperbole, eccentric humour, and much freedom and grossness of delineation, have been undoubtedly derived to us from Rabelais and his admirers. Swift and Sterne were both essentially imitators of this singular genius.

In the seventeenth century Le Sage naturalised the Spanish romance in France. His works present a singular mixture of different styles, although all derived from the same country. In *Gil Blas*, for example (if that work be not actually of Spanish origin), we have something of the humour of *Don Quixote*, the form as well as much of the substance of *Guzman d'Alfarache*, &c.; and much intermixture of a class of tales of love and intrigue, which, coming originally from the Italian novellieri, had acquired a certain chivalrous colouring in passing through the hands of Spanish imitators. There is, moreover, a touch of French taste and philosophy, such as afterwards, when mixed with satire, gave birth to the modern philosophical tale or romance, of which Voltaire's writings contain the best known specimens.

After Le Sage, a new class of romances suddenly grew into fashion in France, the heroic; derived, indeed, in part from an earlier source, the pastoral romance of the sixteenth century. Of these, the *Clélie* and *Cassandre* of Mademoiselle Scudéry were among the most popular examples, although they have long ceased to be read. This species of composition was, in fact, a revival of the old chivalrous romance, without its supernatural marvels, but with even greater exaggeration of sentiment. Its temporary success is to be attributed rather to a caprice of fashion than to the natural progress of taste. It was not, however, wholly without its use, as it called back some degree of sentiment and high feeling into the romance which was in danger of degenerating wholly into a comic cast.

During the eighteenth century the romance and novel enjoyed a popularity, both in England and France, which threw comparatively into the shade every other species of fictitious literature. It would be impossible to continue such a sketch as the present, so as to trace out the various styles and species of those compositions which grew into vogue by the success of distinguished writers in each respective branch. In England, Richardson transferred into ordinary life somewhat of the refined sentiments which distinguished the heroic romance, and thus formed the basis of the modern English novel, properly so called, or novel of manners. His *Pamela* appeared in 1740; his last work, *Sir Charles Grandison*, in 1753. Fielding and Smollett, about the same time, revived the old comic romance, adapted to English scenes and characters. Sterne did the same by the humorous or Rabelaisian style of writing; but added an intermixture of pathos which had certainly never been joined before with so incongruous a companion. To these four writers, in conjunction with Goldsmith's *Vicar of Wakefield*,

confessedly an independent original, almost all the English fictitious prose literature of the last century which is not imitated from foreign works may be said to owe its existence. In France, Marivaux, Prévost, and, with a worse taste than theirs, the younger Crébillon, formed the national manner in this class of writing for some time. Their productions have much of the same character with those of Richardson, but a far lower tone of morality, and less life-like description. But the popularity of the famous *Nouvelle Héloïse* gave a new turn, not only in France, but over Europe, to the public taste in this branch of writing. Marivaux and Prévost may be said to have been Rousseau's models, as to the externals of his great romance; but its tone and sentiment are peculiarly its own. In France, after many inferior imitators, Madame de Staël, the first of female novelists, must be classed as the best and latest disciple of the school of Rousseau. In Germany, his style had even greater success; and he may be said to have called into life at once the taste and the power of that people for fictitious composition. Wieland, Kotzebue, Goethe (*Sorrows of Werther* and *Wilhelm Meister*), are all, though with much originality of their own, essentially followers of Rousseau; Lafontaine, and many other inferior writers, more direct imitators.

In our own times, while the novel of manners continues to maintain its empire in popular estimation, another species of romance—the historical—has likewise acquired a powerful hold on the public taste, which, even more than the first, is chiefly of English origin. The historical romance, in which fictitious scenes and personages are made to serve as vehicles for the historical portraiture of past times, had, especially in Germany, been cultivated with success before the writings of Sir Walter Scott; but it is to his adoption of this branch of composition, and the extraordinary talent which he devoted to it, that its recent popularity may be traced.

Romance Languages. A name given to those modern languages which are closely akin to the old language of the Romans, and which are modifications of the ancient Italian dialects: of these, six still remain literary dialects, the languages of Portugal, Spain, France, Italy, Wallachia, and the Grisons of Switzerland. The Provençal, or language of the Troubadours, is now a mere patois. [LANGUAGE.]

Romancero. In Spanish, the general name for a collection of the national ballads or *romances*; so called from the word *Roman* or *Romanic*, which, in the early part of the middle ages, seems to have been the common appellation of all the dialects spoken from the Alps to the western extremity of the Mediterranean. The *Romancero General*, the most celebrated of these collections, was published in 1604–14.

Romanese Language. The language of the Wallachians, who call themselves Romàni. It is spoken in Wallachia, Moldavia, and in parts of Hungary, Transylvania and Bessarabia, and is divided by the Danube into two branches, the northern being to a certain extent a literary language; the southern has borrowed many Greek and Albanian words, and has never been fixed grammatically. (Max Müller, *Lectures on Language*, first series, 182.)

Romanesque (Fr.). In Architecture. [ARCHITECTURE, GOTHIC.]

ROMANESQUE. In Painting, appertaining to fable or romance. In historical painting, it consists in the choice of a fanciful subject, rather than one founded on fact. *Romanesque* is different from *romantic*; because the latter may be founded on truth, which the former never is.

Romantic, Romanticism. By *romantic* is understood that singular intermixture of the wonderful and mysterious with the sublime and beautiful which introduces us into an enchanted existence. [CHIVALRY.]

Almost all authors agree in acknowledging the difficulty of giving a precise signification to the term *romantic*. The *Dictionnaire de l'Académie Française* says, 'Le romantique est un genre nouveau. *Romantique* se dit encore des écrivains qui affectent de s'affranchir des règles de composition et de style établies par l'exemple des auteurs classiques.'

The term *romanticism*—an offshoot of romantic—is of recent invention, and is applied chiefly to the fantastic and unnatural productions of the modern French school of novelists, at the head of which are Victor Hugo, Balzac, 'George Sand,' &c., and their imitators in France and other countries.

Romanzieri. In Italian Literature, a series of poets who took for the subject of their compositions the chivalrous romances of France and Spain; and chiefly those relating to the exploits of Charlemagne and his fabulous Paladins. [ROLAND; SIGURDR.] The earliest of these poets flourished in the latter end of the fifteenth century. Boiardo, although not absolutely the first in order of time, is considered as having laid the groundwork, in his *Orlando Innamorato*, of the edifice of fiction raised by his successors. Pulci, in the *Morgante Maggiore*, was the first who allied the romantic incidents and sentiments of chivalry with light and humorous satire. Berni remodelled the work of Boiardo. Ariosto, in the *Orlando Furioso*, carried this species of poetry to the highest degree of perfection. These are the four principal Romanzieri; but many other poets of the same school flourished until the end of the sixteenth century. Tasso composed one of his early poems (*Il Rinaldo*) on the common model. In the beginning of the eighteenth century, Fortiguerra compiled his *Ricciardetto*, a poem of a semi-burlesque character, intended originally as a parody, but completed as a serious composition; and thus closes the list of the Romanzieri. All these poets adopted the OTTAVA RIMA, invented by Boccaccio. In their poems the thread of the main narration is frequently interrupted by a multiplicity of minor adventures

and intrigues; and this complication of plot appears to have constituted one of the characteristic features of the chivalrous epic. In most of them (from the time of Pulci) each book begins with a sort of prologue, more or less connected with the subject which follows: and these prologues form perhaps the greatest charm of the poem of Ariosto, effecting the transitions from one subject to another by means of some touch of pathetic or elevated reflection, or of light humour and playful satire, generally in the form of an address to the supposed audience, the poem being framed on the model of a tale recounted by a minstrel to an assembly of knights and ladies.

Romanzowite. A brown or brownish-black variety of Lime-Garnet occurring in compact or crystalline plates, at Kimito in Finland. It is a triple silicate of lime, alumina, and iron, and was named after Count Romanzow.

Romeine or **Romeite.** A native antimoniate of lime found in the manganese mines of St. Marcel in Piedmont, and named in honour of the celebrated crystallographer Romé de l'Isle.

Romulus (Lat.). In Mythology, the supposed founder of the city of Rome, of which he is the eponymous hero, as Arcas is of Arcadia, and as Ion, Æolus, and Dorus represent respectively the Ionians, Æolians, and Dorians. In its several incidents the tale of Romulus presents a close parallel to the legends of other mythical heroes. The resemblance to the myths of Cyrus and Chandragupta (Max Müller's *History of Sanskrit Literature*, 283 &c.) is especially striking. In all these, as in the tales of Paris, Œdipus, Telephus, and Perseus, there is the exposure of the children and their wonderful rescue, generally by some beast in the first instance, as a wolf [LYCAON], a bear [RISHIS, THE SEVEN], or a dog. In all cases the children grow up pre-eminent in grace and majesty, and their royal bearing is the cause which leads to the discovery of their parentage. Like ŒDIPUS, Romulus is taken from the sight of men in a storm of thunder and lightning. [QUIRINUS.]

The incidents of his reign are made up of local and institutional legends, as of the Asylum, the Lupercalia, of the Ramnenses, Titienses, Luceres, &c., while into these tales later writers introduced the element of plausible fiction. But, as in the annals of the Teutonic conquests in England, the chronology is altogether artificial. The heroic secle was a period of 77 years, and this secle was made to include the reigns of Romulus and Numa; and as the cyclical year was divided into 38 nundines, one of these was assigned to the interregnum, and 37 were given to the reign of Romulus. Thus, if twice 38 were to be allotted to the first two kings, 39 fall to Numa's share; and this period is assigned to the latter in one account. In Livy, Numa's reign is stated at 43 years; but if this sum be added to the 37 of Romulus with the year of interregnum we have 81, the biquadrate of 3. (Niebuhr, *Hist. of Rome*; Sir G. C. Lewis, *Astronomy of the Ancients*, p. 50; Lappenberg, *Hist. of England*, i. 77.) [TABULATION OF CHRONOLOGY.]

Rondeau (Fr.). In French Poetry, a little poem of thirteen verses, divided into three unequal strophes, with two rhymes (eight lines masculine and five feminine, or vice versâ). The first two or three words of the first verse serve as the burden, and recur in that shape after the eighth and thirteenth verses. There are also double rondeaux and single rondeaux; the latter an obsolete, but easier kind of verse.

Rondo (Ital.). In Music, a light form of composition in which the subject or theme returns frequently. It usually forms the last movement of a symphony or sonata, but is also very common as a separate composition.

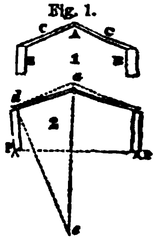
Rood (A.-Sax. rode, *a beam*; used for the cross). The crucifix, with the images of St. Mary and St. John, sometimes also the image of a saint, was so called in English old churches. The place where the rood stood was called the *rood-loft*, which was commonly over or near the passage out of the body of the church into the chancel. They were all ordered to be taken down in 1548 (Burnet, *History of the Reformation*, vol. ii. book i.); but were restored for a short time under Queen Mary. Among the few that escaped the second removal, one of the finest is in the church of Charlton-on-Otmoor, Oxon. The screens dividing the choirs from the naves of most of our cathedrals are old rood-lofts from which the images have been removed.

ROOD. A square measure, the fourth part of a statute acre, and equal to forty perches or square poles.

Roof (A.-Sax. hrof, Gr. ὀροφή). In Architecture, the uppermost part of a building, containing the timber work or the iron work, with its covering of slate, tiles, lead, or other materials. Carpenters, however, restrict their use of the word *roof* to the timber framing alone.

A roof, as regards its construction, involves some knowledge of mathematics, especially since the introduction of ironwork has enabled architects to attempt much greater spans than were formerly thought justifiable. Of the general principles on which the proper construction of a wooden roof depends, we shall here subjoin some account, leaving the construction of iron roofs to be discussed somewhat briefly under STATIONS, RAILWAY.

Fig. 1.



The obvious mode of covering a building where a greater or lesser inclination of the sides of the roof is required by the climate, is to place two sloping rafters C C upon the walls BB, as in the subjoined diagram, meeting at the apex A, where we will suppose them so connected with a hinge, but capable of descending by their own gravity, as shown in No. 2. The walls are considered as solid masses, movable on the points PP. If the

walls be not of sufficient weight, the thrust exerted upon them by the tendency of the rafters to spread at their feet, will throw the walls outwards, as in No. 2, and the whole structure will be destroyed. By the laws of mechanics it is known that the horizontal thrust thus acting upon the wall is proportional to the length of a line *de*, drawn at right angles to the rafter, intersecting a vertical line drawn from the apex, which, it must be evident, must increase as the roof gets flatter. To counteract the thrust above named, nothing more is necessary than to tie together the feet of the rafters as in the following diagram (fig. 2), in which A B is the tie in question, and thence called the *tie-beam*. If the extent be not very great, the rafters may be kept from spreading by a minor tie, at *ab*, called *a collar*.

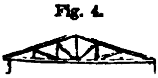
Fig. 2.

Beyond certain lengths, or spans, however, it will occur to the reader that a tie-beam will itself have a tendency to bend, or to *sag* as the workmen call it, in the middle; and from this circumstance a fresh contrivance becomes necessary, which will be seen in the diagram below marked *cd* (fig. 3); this is called a *king post*, or more properly a *king piece*, inasmuch as it does not perform the office of a post, but rather of a tie, for it ties up the beam to prevent its sagging.

Fig. 3.

If the rafters be so long as to be liable to bend, two pieces *aa*, called *struts*, are introduced; which having their footings against the sides of the king posts, act as posts to support or strut up the rafters at their weakest points. The piece of framing thus contrived is altogether called a *truss*, and in the particular case considered it is called a *king truss*. It is obvious that by means of the upper joints of the struts we obtain more points of support for the rafters, or rather points of suspension, and that but for the compressibility of the timber, there would be no limit to the space which a roof might be made to span.

Fig. 4.



This compressibility takes effect where the fibres of the wood are pressed at right angles, or nearly so, with their direction, and many ways are adopted for avoiding this inconvenience. There is a species of roof, dependent in construction on the principles thus described, of which the following is a diagram (fig. 5). Its principles are the same as those already mentioned, and do not here require further notice; this roof has three points of support A B A,

Fig. 5.

the posts A A, A A, are called *queen posts*, the collar A B A is here a *straining piece*, instead of a tie, as it was in the example at first noticed, its operation being, in fact, the exact reverse of a tie. The *curb* or *mansard roof* is one which has the advantage of affording an additional story in the roof, but it requires little illustration from us beyond the drawing subjoined (fig. 6). In the execution of roofs the expense of trussing every pair of rafters would be unnecessary, and the practice would also load the walls with a far greater weight than would be expedient; it is, therefore, the custom to place the principal parts of a roof at certain intervals, which, however, should as a general rule never greatly exceed ten feet.

Fig. 6.

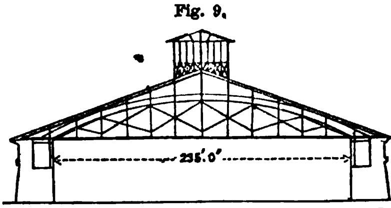
The rafters which are actually trussed are called *principal rafters*, and by the intervention of the *purlin* A in the diagram (fig. 7) they are made to bear the smaller or *common rafters*, which are notched down on to it. These common rafters are received by, or pitch upon, a plate B, called *a pole plate*; and the principal rafters which fall upon the tie-beam are ultimately received upon the wall-plate C.

Fig. 7.

When beams in either roofs or floors are so long that they cannot be procured in one piece, two pieces to form the adequate length are scarfed together, by indenting them at their joints and by bolting them together; of which practice two modes are here represented (fig. 8). It may be of interest to remark that up to the width of span of 40 feet, the practice of architects is to adopt the king post description of roofing; beyond 40, and up to as much as 120 feet, they usually adopt the queen post roofing; but the recent improvements in carpentry, by the adoption of Colonel Emy's principle of forming arches of planks, bent whole, and by Colonel Ardunt's system of polygonal framing, &c., have introduced many new methods of spanning great dimensions. Figs. 9 and 10

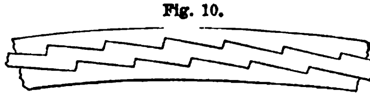
Fig. 8.

Fig. 9.



will show the mode of construction adopted in the remarkable roof of the imperial riding-house at Moscow, built in 1790, the span of which is 235 feet. An arched beam formed in three thicknesses, notched into one another, as shown in fig. 10, is first constructed, and the

Fig. 10.



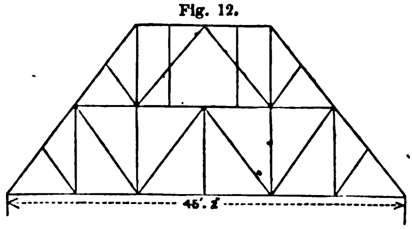
ends of this beam are tied together by a tie-beam running across the chord of the arc, while cross trussing connects the arch and the beam firmly together. Fig. 11 is a representation of Colonel Emy's plank arch as constructed by him, in 1825, for the roof of a building near Bayonne; the principals, wall posts, and arched rib, form two triangles firmly

braced together the whole weight of the roof being thrown at the wall at the feet of the ribs, and not upon the pole-plate. Many, and indeed most, of the modern roofs of large span are now formed of wrought iron. That of the

Fig. 11.

new houses of parliament at Westminster is thus constructed, and the tie-beams and suspension rods are of flat bar iron, the principal and common rafters of T iron, while the struts and purlins are of cast iron, the whole being

Fig. 12.



fitted together with cast-iron shoes. The principle of construction of the roof over the House of Lords is shown in fig. 12.

Rook (A.-Sax. hroc). The name of a well-known species of crow (*Corvus frugilegus*, Linn.), resembling in size and colour the carrion crow, but differing in having the base of the bill whitish and scurfy, and bare of feathers. 'This,' says Montague, 'is acquired by the bird's habit of thrusting its bill into the ground after worms and various insects. The rook derives much of its food from the insect tribe, particularly the larvæ of the cockchafer; and while following the plough to remove from the newly-made furrow this destructive grub, it more than repays the husbandman for the grain which it may afterwards pick up. The rook is gregarious at all seasons, resorting constantly to the same trees every spring to breed, when the nests may be seen crowded one over another upon the upper branches. It lays four or five eggs, much like those of the crow, of a greenish colour, spotted and blotched with dusky. After their young have taken wing, they all forsake their nest-trees, returning to them again in October to roost; but as winter comes on, they generally select more sheltered places at night in some neighbouring wood, to which they fly off together.' (Montague, *Ornithological Dictionary.*) The wood or grove of tall trees, in which rooks congregate and build their nests, is called a *rookery*.

Rook. [Chess.]

Room and Space. In Shipbuilding, the technical expression for the length of the vessel supported by each rib or timber. This varies from 2 feet 6 inches to 3 feet 9 inches, according to the strength required, the weight of the whole structure of the ship being proportioned to the closeness of the timbers together. It is an axiom that the minimum of weight consistent with the requisite firmness, gives the maximum for stowage or speed. The *room and space staff*, called also the *station*, is a marked rod for measuring the room and space on the keel.

Roosts. [Races.]

Root (Dan. rod, Swed. rot). In Arithmetic, a number which, multiplied by itself a stated number of times, is equal to a given number; in other words, the number of which a given number is a stated power. The index of the root is the same as that of the power. Thus the fourth root of 16 is 2, and is denoted by the symbol $\sqrt[4]{16}$. In the most frequently occurring case of square root the index 2 is omitted, and the *radical sign* $\sqrt{\ }$ alone used. [Extraction of Roots.]

The more general and algebraic definition of a root, is any value of an unknown quantity which satisfies a given equation. [Equation.] Thus the ordinary or arithmetical root $\sqrt[n]{a}$ of a number a is merely one of the n roots of the equation

$$x^n - a = 0,$$

a general symbol for which is $(a)^{\frac{1}{n}}$.

The remaining roots are all imaginary when n is odd; and when n is even, one of them is real and negative $-\sqrt[n]{a}$, and the rest imaginary; that is to say, of the form $a + b\sqrt{-1}$, where a and b are real, positive, or negative numbers, all the n roots of a number may be obtained by multiplying its arithmetical n^{th} root into the n *roots of unity*, which latter are easily obtained from *Demoivre's formula*, since $(1)^{\frac{1}{n}} = (\cos\theta + \sqrt{-1}\sin\theta)^{\frac{1}{n}}$ when $\theta = 0$. [Demoivre's Theorem.]

Root. In Vegetable Physiology, that part of the central axis of a plant which is formed by the descending fibres, and whose function is to attract liquid food from the soil in which it is mingled. It differs from the stem in not having leaves or buds upon its surface, and in its tendency to burrow under ground, retreating from light; nevertheless, some kinds of roots

are exclusively formed in air and light, as in the ivy, and other such plants, and also in epiphytes.

Root of Scarcity. One of the names of the Mangold Wurzel.

Roots. In Language, roots are of two kinds, roots demonstrative and roots predicative. The former are properly pronouns; the latter comprise all names, whatever may be the form assumed by them, and express invariably some sensible or material idea. Thus the words *mill* and *meal*, *milk*, *mild*, *immortal*, &c. &c., are traced back to a root, *mar* or *mal*, which expressed originally the sound of crushing or grinding. From this root have sprung words which have apparently nothing in common with each other.

To account for these roots, two theories have been put forward. On the one hand, Prof. Max Müller, adopting substantially the hypothesis of Plato, traced them, in his first series of *Lectures on Language*, to phonetic types, which had a certain congruence and connection with the objects signified. According to this theory, 'each substance has its peculiar ring. We can tell the more or less perfect structure of metals by the answer which they give. Gold rings differently from tin; wood rings differently from stone; and different sounds are produced according to the nature of each percussion. It was the same with man, the most highly organised of Nature's works. Man in his primitive and perfect state was endowed not only, like the brute, with the power of expressing his sensations by interjections, and his perceptions by onomatopœia; he possessed likewise the faculty of giving more articulate expression to the natural conceptions of his mind. That faculty was not of his own making; it was an instinct, an instinct of the mind as irresistible as any other instinct. So far as language is the production of that instinct, it belongs to the realm of nature; man loses his instincts as he ceases to want them. His senses become fainter when, as in the case of scent, they become useless. Thus the creative faculty which gave to each conception, as it thrilled for the first time through the brain, a phonetic expression, became extinct when its object was fulfilled.'

This theory is opposed by those philologists, who maintain the mimetic or onomatopoetic origin of all languages, and who assert that the idea of phonetic types involves a realistic hypothesis in the essential relation of sound to the thing signified by the sound. Professor Max Müller's theory, it is argued, seeks to account for a physical fact by referring it to a metaphysical cause, of the existence of which the alleged effect is the only evidence; the instinct which led man in his primitive state to connect certain sounds with certain ideas, being indicated only by the fact which it professes to explain. Thus, this instinct is an ideal cause set in operation only to satisfy a need of the intellect; and as no one maintains the present operation of this cause, its operation in an earlier stage is a mere metaphysical hypothesis. It is further maintained, that as an imitative origin of certain words is conceded on all hands, the mimetic origin of all language becomes a question relating to the limits of operation of a particular principle, and not to the fact of its existence. Thus it is admitted that such a sound as *pat* may be fairly claimed as imitative; but from this root comes the Greek *πάτος*, and the English *path*, words not specially suggestive of sounds connected with a mimetic root. If, then, this is confessedly the case with some words, why, it is asked, may it not be so with all words? This hypothesis, or rather this statement of facts in certain instances ascertained, is, it is added, the only one that joins the present to the past, while it does not endow our forefathers with instincts of which their children know nothing, the whole burden of the argument being thus thrown on those who impugn this theory. It is further argued that the idea of any relation of sound to the thing signified is a fallacy which has sprung from immemorial association, and that the link forged by imagination has been accepted as existing in nature; that this fallacy is dispelled by the fact of the diversity of languages, which shows that sounds varying indefinitely from each other may be used to express the same notions, and proves that there is no essential connection or congruence between words and things. This argument calls into question the absolute necessity of language, not merely as the vehicle, but as the condition of thought; and while it allows that thought and language are seldom separated in fact, denies that this is never the case, or that the rarity of the fact is anything more than a consequence of human weakness. Finally, it regards the roots or original constituents of language, as mere unmeaning sounds, which attained significance only by being modified to denote objects in which a resemblance may be traced to another object suggested by the original sound, the sum of the whole being that the past is uniform with the present and that the results which the theory of phonetic types traces to an agency now unknown, are due to the mere continuance of causes still everywhere at work. (Max Müller, *Lectures on Language*, first and second series; Farrar, 'Chapters on Language,' *Westminster Rev.* Jan. 1865, July 1866, *Edin. Rev.* Jan. 1862, *Quart. Rev.* April 1866.)

Roots, Primitive. [PRIMITIVE ROOT.]

Roots, Singular. [SINGULAR ROOTS.]

Roots, Squared Differences of. [EQUATION OF SQUARED DIFFERENCES.]

Roots, Symmetric Functions of. [SYMMETRIC FUNCTIONS.]

Roots of Unity. In Algebra, any real or imaginary quantity which multiplied by itself a certain number of times is equal to unity, is termed a *root of unity.* [ROOT.] Owing to the importance of the roots of unity in many algebraical enquiries, we add here a few of their more important properties; for demonstrations, as well as for further details, the

reader may consult any good treatise on the theory of equations. 1. Every positive or negative integral power of an n^{th} root of unity is itself an n^{th} root of unity. 2. Unity itself excepted, no n^{th} root of unity can be at the same time an m^{th} root, when m and n are prime to each other. 3. If n be a prime number and a any n^{th} root of unity (unity itself excepted), the remaining $n-1$ roots will be $a^2, a^3, a^4 \dots a^n$. This property also holds when n is not prime, provided a is a *primitive n^{th} root* of unity, that is to say, provided it is not at the same time a root of unity of a lower order than the n^{th}. 4. The continued product of a p^{th}, q^{th}, r^{th} &c. . . . root of unity is a $(p\,q\,r\dots)^{th}$ root, so that n being a composite number all the n^{th} roots of unity may be formed by the multiplication of roots of a lower order. 5. The sum of all the n^{th} roots of unity vanishes, as does also the sum of their homogeneous products, provided the dimension of each product is less than n. 6. The product of all the n^{th} roots of unity is equal to $(-1)^{n+1}$. 7. The sum of the m^{th} powers of the several n^{th} roots of unity has the value n or 0, according as m is or is not a multiple of n.

Rootstock. [RHIZOME.]

Rope (A.-Sax. rap, Ital. ropa). A certain proportion of fibres of hemp twisted together form a yarn, and a number of yarns form a strand. Three strands twisted together form a rope. The size of the rope depends on the number of yarns contained in it. Rope is either white or tarred, the latter being the best if liable to exposure to wet, the former if not exposed. The strength of tarred rope is, however, only about three-fourths that of white rope, and its loss of strength increases with time. Rope is designated by its circumference, expressed in inches, and is issued in coils of 113 fathoms each; marline and Hambro' line in skeins, spun yarn in pounds: the latter is made from old rope. Government rope is distinguished by a coloured thread, red, blue, or yellow, which runs through it. Rope used in the artillery service is coiled *with the sun*, i.e. from left to right, in which direction the yarns are twisted, so as to avoid *kinking*.

The strength of white hempen rope may be approximately calculated by the following rule, viz.: square the circumference, and divide by five for the number of tons *dead weight* that the rope will bear. But the strain caused by a sharp jerk upon a rope is very much greater than that of a dead weight. The special committee of the Alpine Club reports: 'The strain upon a rope loaded with a weight of fourteen stone, and suddenly checked after a fall of eight feet, is nearly equal to that which is caused by a dead weight of two tons.' [KNOTS.]

Other materials besides hemp are used in the manufacture of rope, but to a smaller extent. Coir rope, which comes from Ceylon and the Maldive Islands, is made from the fibrous husk of the cocoa-nut; Manilla rope from the fibres of a species of wild banana. Wire rope, both iron and steel, is also employed.

Rope-dancer. Among the Greeks the rope-dancer was known by the name σχοινοβάτης, the Latin designation being *funambulus*. The agility of the Roman rope-dancers is illustrated in many paintings discovered in excavations. (Smith, *Dictionary of Antiquities*, s.v. 'Funambulus.')

Rosaceae (Rosa, one of the genera). A large and important Natural Order of perigynous Exogens, the species of which are for the most part inhabitants of the cooler regions of the world. They are in some cases trees, in others shrubs, and in a great number of instances herbaceous perennial plants; scarcely any are annuals. No natural orders contain more species of general interest, in the beauty of their flowers or their perfume. Among the more choice are the Rose itself, and various species of the genera *Rubus*, *Spirea*, *Potentilla*, *Geum*, and *Pyrus*. The Apple, Pear, Plum, Cherry, Peach, Nectarine, Apricot, and similar valuable fruits, are the produce of others. The Whitethorn, with all its numerous exotic allies, belongs to the genus *Crataegus*. As medicinal plants, some are of considerable importance. The root of *Potentilla reptans*, *Geum urbanum*, and others, is powerfully astringent; the bark of *Prunus Cocomilia* has some reputation as a febrifuge; an Abyssinian plant called *Brayera anthelmintica* has energetic vermifugal qualities; and, finally, prussic acid is obtained from the leaves and seeds of the Almond, Peach, Plum, and other related species. This important assemblage of plants is distinguished by having several petals; separate carpels; distinct, perigynous, numerous stamens; alternate leaves, and an exogenous mode of growth.

Rosarium, Rosary. [ROSETUM.]

Rosary (Lat. rosarium, *a rose-bed*). A Roman Catholic devotional practice; which consists in reciting fifteen times the Paternoster, or Lord's Prayer, and 150 times the Ave Maria, or angelical salutation; but as the computation is made by means of beads, the string of beads used for this purpose has acquired the popular name of a rosary. The rosary is thus three times the ordinary chaplet. It is instituted in honour of the fifteen principal mysteries in the life of Christ and of the Virgin Mary. Some have attributed its institution to St. Dominic; others, among whom is Mosheim (cent. x. part ii. c. iv.), give it a higher antiquity. The festival of the Rosary falls on the first Sunday in October. Its name was changed by Gregory XIII. from that of St. Mary of the Victory, given by Pius V. on its original institution in honour of the battle of Lepanto, which took place on that day.

Rose (Lat. rosa. Gr. ῥόδον). In Architecture, the sculptured representation of this flower is found in the centre of each face of the abacus in the Corinthian capital, and is called the rose of that capital. Roses are also used to decorate the caissons in the soffits of coronas and ceilings.

ROSE. In Botany, the English name for

a well-known and universally cultivated flower, belonging to the genus *Rosa*. [ROSACEÆ.]

Rose Engine. In Mechanics, an appendage to the turning lathe, by which a surface of wood or metal, as a watch-case, is engraved with a variety of curved lines. The assemblage of these lines presenting some resemblance to a full-blown rose, is called by the French *rosette*; and hence the engine by which the ornament is produced is called a rose engine. The mechanism by which the figures are produced is composed of one or more plates or cams set on the axis of the turning lathe, or suitably rotated and formed with waving edges or grooves, which govern, in a manner corresponding to the pattern of the edges or grooves, the movement to or from the centre of the cutting point. The combination of the rotatory motion of the lathe and the radial motion of the tool cuts figures corresponding to the nature of the radial motion given.

Rose Quartz. A beautiful variety of Quartz of a rose-red or pink colour, and nearly transparent. Large masses of a most delicate rose colour are to be obtained in the vicinity of Ratnapoora in Ceylon, and it is also found in Aberdeenshire, the Shetlands and Hebrides, near Belfast, Rabenstein in Bavaria, &c.

Roses, White and Red. In English History, the well-known feuds that prevailed between the houses of York and Lancaster are so called, from the emblems adopted by their respective partisans; the adherents of the house of York having the white, those of Lancaster the red rose, as their distinguishing symbol. These wars originated with the descendants of Edward III.; and after extending over a period of more than eighty years of bloodshed and devastation, were finally put an end to by the victory of Henry Tudor, earl of Richmond, over Richard III. in 1485, the victor uniting in his own person the title of Lancaster through his mother, and that of York by his marriage with the daughter of Edward IV. Since that period the rose has been the emblem of England, as the THISTLE and SHAMROCK are respectively the symbols of Scotland and Ireland.

Rose-noble. A gold coin of the value of 6*s.* 8*d.*, first coined in the reign of Edward III.

Roselite. A deep rose-red variety of Cobalt Bloom containing lime. It is met with at Schneeberg in Saxony, and was named after Gustave Rose of Berlin.

Rosellane (Eng. *rose*). An altered Anorthite, according to G. Rose. It is a hydrated silicate of alumina, lime, magnesia and potash, tinged red by manganese, and occurs in small grains embedded in limestone in Sweden and Finland. [ROSITE.]

Roselle. The name given to *Hibiscus Sabdariffa*, the ripened calyces of which have a pleasant acid flavour, and are used both in the East and West Indies for making tarts and jellies, and also a cool refreshing drink.

Rosemary (Lat. ros marinus, *sea-dew*). This name is given to a small evergreen shrub of the Labiate order, which inhabits rocky hills in the neighbourhood of the Mediterranean, and is commonly cultivated in our gardens. It has very narrow green leaves, turned back at the edge, and hoary underneath. The flowers are of a dull greyish blue. It has been employed in infusion as a remedy for headache, and is extensively used in the manufacture of pomatum for promoting the growth of hair. Oil of rosemary gives the green colour to these preparations. It is also said to be one of the ingredients in Eau de Cologne. Narbonne honey is stated to owe its peculiar flavour to bees feeding on the blossoms of the rosemary. The grey bushes, mantled with dewdrops, on the rocky coasts of France and Italy, justify, it is said, the singular name given to the plant. It is the λιβανωτὶς στεφανωματικὴ of Dioscorides.

Rosenite. The name given by Zincken to Plagionite, in compliment to H. Rose, the analytical mineralogist.

Roseola (Lat. roseus, *rosy*). A rash, so called from its rose colour. It is frequently symptomatic of different febrile complaints, of disordered stomach and bowels, of teething, and of any constitutional irritation. Acidulated drinks, mild aperients and sudorifics, and strict attention to the diet, with caution against the application of or exposure to cold, so as to cause a retrocession, are the principal points to be attended to.

Rosetta Stone (so called from Rosetta, a village of Egypt, where it was discovered by the French). The name given to the celebrated stone, now in the British Museum, which has played so distinguished a part in all modern hieroglyphical researches. It is a piece of black basalt, three feet in length, and about two feet and a half in breadth, and contains parts of three different sculptured inscriptions: one in sacred characters, or, as they are termed, *hieroglyphics*; the second in enchorial characters (i. e. in those of the country, or in modified conventional hieroglyphics); and the third in Greek. The inscriptions are a good deal mutilated, particularly the hieroglyphical; but they are still sufficiently distinct to allow the hieroglyphical and enchorial characters to be compared with each other and the Greek. As the discovery of this stone presented to the learned the first opportunity of viewing the Greek in juxtaposition with the Egyptian language, great hopes were entertained that a key would thereby be obtained to the deciphering of the numerous monuments of ancient Egypt. It would appear, however, from the investigations of Dr. Young and Champollion, that the Greek does not faithfully represent the enchorial text, but gives merely its substance. According to the Greek inscription, the stone was erected in the reign of Ptolemy Epiphanes (A. C. 194), whose benevolence it describes, enumerating his victories and the principal political transactions of his reign. (Sir G. C. Lewis, *Astronomy of the Ancients*, p. 387.) [ALPHABET; HIEROGLYPHICS.]

Rosetta Wood. The name of a handsomely veined Indian wood, of hard texture, and a lively orange-red colour, the source of which does not appear to be ascertained.

Rosetum (Lat. *a rose-bed*). A garden or parterre devoted to the cultivation of Roses, of which flower numberless varieties are now found in cultivation, chiefly of the class called Hybrid Perpetuals, a race which combines with great variety and beauty in the blossoms themselves, a habit of flowering successionally through the autumn, which renders them especially valuable for garden purposes. A Rosetum should be laid out formally, with beds either on grass or gravel for the dwarf-habited plants, while standard roses, weeping roses, and pillar or climbing roses are introduced at pleasure to vary the effect.

Rosewood. There are various kinds of Rosewood. That of the Canary Islands, valued for its fragrance, has been already noticed. [RHODORHIZA.] The more important, however, are the valuable South American ornamental timbers so designated, and which appear to be produced by several species of *Dalbergia*. That most esteemed, obtained from Rio Janeiro, is said to be chiefly produced by *D. nigra*; but inferior sorts are probably yielded by *Machærium firmum, incorruptibile*, and *legale*—trees which bear the name of Jacaranda in Brazil; and it is also attributed by Lindley to species of *Triptolemæa*. Some of the species of *Pterocarpus*, again, yield timber so called, African Rosewood being the produce of *P. erinaceus*, and Burmese Rosewood that of *P. indicus*. Some of the Indian Rosewoods are attributed to *Dalbergia latifolia* and *D. sissoides*.

Rosicrucians. A sect of visionary speculators in Germany about the beginning of the seventeenth century. At this time Germany was inundated with tracts, purporting to come from supporters or from enemies of this sect. From one of these, a *Treatise on the Laws of the Rosicrucians*, by Ritter von Maier (1619), we learn that the fraternity had six fundamental laws: 1. That their chief end and object was to cure the sick without fee or reward. 2. That in travelling they were to change their habits and dress, so as to accommodate themselves to those of the countries in which they sojourned. 3. To meet once a year on a certain day and at a certain place, kept secret from the rest of the world. 4. To fill up vacancies in their body by electing fresh members. 5. To use the letters R. C. as their common symbol. 6. That the fraternity should remain undivulged for one hundred years from its foundation. It appears probable that the device of the rose issuing out of the cross, which was the same as Martin Luther's seal, was adopted for the purpose of attracting the notice of the religious: the rose was explained to represent the blood of Christ. It would appear from these laws that some species of secret Freemasonry was intended; and the Rosicrucians have been by some connected with the Freemasons; but there is, in point of fact, no evidence that any such society existed at all. Valentine Andreä, a Lutheran clergyman, is said to have been the original propagator of the reports concerning the Rosicrucian society; and to him is ascribed the treatise, published in 1610, entitled, *The Discovery of the Brotherhood of the Honourable Order of the Rosy Cross*. In this book he merely calls on all who wish to lessen the amount of human ignorance, suffering, and degradation, to come forward and give their names. Owing to the superstitious character of the age, the hoax failed, and the title became a term denoting every kind of occult and magical science. (Hallam, *Literary History*, part iii. ch. iv. § 39.) The Rosicrucians have been connected in various ways, by public opinion, with the Cabalists, Illuminati, &c.; and the division of spiritual beings inferior to the angels into sylphs and gnomes, which furnished Pope with the machinery of the *Rape of the Lock*, is of Rosicrucian or Cabalistic origin. It is found in that singular work by a professed Rosicrucian, the *Comte de Gabalis*, which obtained a sudden popularity in the beginning of the last century.

Rosin. [RESIN.]

Rosin Tin. A miner's name for pale-coloured translucent Tinstone with a resinous lustre.

Rosite. A mineral of a red colour in small grains, embedded in limestone, from Sweden; it appears to be silicate of alumina tinged red by manganese. It has also been called ROSELLANE.

Rosstrevorite. A fibrous variety of Epidote, met with in Ireland at Rosstrevor, county Down.

Rostellate (Lat. rostellum, dim. of rostrum, *a beak*). In Botany, a term applied when any part terminates gradually in a hard long straight point, as the pod of a radish, the capsule of many mosses, &c.

Rostellum (Lat. dim. of rostrum, *a beak*). The name of the mouth of the louse and similar Apterous insects, in which the ordinary trophi are replaced by an exarticulate retractile tube, from which a retractile siphuncle is protruded. The uncinated proboscis of the tape-worms (*Tæniæ*) is also so called.

ROSTELLUM. In Botany, an elevated and rather thickened portion of the stigma of Orchidaceous plants, from which the peculiar gland separates by which the pollen masses of some species of that order are eventually held together. It was formerly supposed to be the point through which impregnation is effected, but this is now known to have been an error.

Roster or **Rollster.** A Military term, implying the seniority list, from which officers are detached for duty in regular succession.

Rostrulum (from Lat. rostrum). In Entomology, the name of the oral instrument of the flea and other *Aphanipterans*; in which the ordinary trophi are replaced by a bivalved beak, between the valves of which there are three lancet-shaped instruments.

Rostrum (Lat. *a beak*). A name applied

metaphorically to the pulpit or pleading-place in the Roman forum, which was decorated with the prows of vessels taken from the enemy.

Rosulate (Lat. rosa, *a rose*). In Botany, this term is applied to those collections of petals or leaves which are packed over each other in many rows, as the blossom of a double rose, the offset of the Houseleek, &c.

Rot (A.-Sax. rotian, *to rot*). A term applied to a well-known disease peculiar to sheep: also termed *cothe*, but more generally known by the term *rot*. Many causes have been assigned for it; as the *Fasciola hepatica* or fluke worm, or some particular plants taken as food; but as most of the supposed deleterious herbs have been tried by way of experiment, and have failed to produce the disease, it must be attributed to some other cause. It is believed that the germs from which the fluke is derived, are taken into the system with the grasses and other green food grown in marshy ground. Bakewell, when his sheep were past service, used to rot them purposely by feeding them on wet land, that they might not pass into other hands. This he always readily did by overflowing his pastures. It is said that land on which water flows, but does not stagnate, will not rot, however moist; but this is contradicted by the experience of Bakewell, who used merely to flood his lands a few times only to rot his sheep. It is also said that they are safe from rot on Irish bogs, salt marshes, and spring-flooded meadows, a statement apparently verified by experience. When salt marshes are found injurious, it is only in years when the rain has saturated or rather super-saturated such marshes. The assertion that putrid exhalations unaccompanied with moisture can occasion rot, needs confirmation; for these commonly go together, and it is difficult to separate their effects. It is not the quantity of water immediately received by land, but the capacity of that land to retain the moisture, which makes it good breeding ground for the germs of the disease, and thus makes the land itself of a rotting quality.

The signs of rottenness are sufficiently familiar to persons about sheep. They first lose flesh, and what remains is flabby and pale; they also lose their vivacity. The naked parts, as the lips, tongue, &c., look livid, and are alternately hot and cold in the advanced stages. The eyes look sad and glassy, the breath is fœtid, the urine small in quantity and high-coloured; and the bowels are at one time costive, and at another affected with a black purging. The wool will come off on the slightest pull in almost all cases. The disease has different degrees of rapidity, but is always fatal at last. This difference in degree occasions some rotted sheep to thrive well under its progress to a certain stage, when they suddenly fall off, and the disease pursues the same course as with the rest. Some graziers know this crisis of declension, as it has been called, and kill their sheep for market in the immediate nick of time with no loss. In these cases, no signs of the disease are to be traced by ordinary inspectors; but the existence of the flukes, and still more a certain state of liver and of its secretions, are characteristic marks to the wary and experienced.

The treatment of rot is seldom successful, unless when it is early commenced, or when the disease is of a mild nature. A total change of food is the first indication, and of that to a dry wholesome kind: all the farinæ are good, as the meals of wheat, barley, oats, peas, beans, &c. Oilcake is good also. Carrots have done good, mixed with these: broom, burnet, elder, and melilot, as diuretics, have also been recommended; but it is necessary to remark, that there is seldom any ventral effusion but in the latter stages of the complaint. As long as the liver is not disorganised, a cure may be looked for by a simple removal of the cause, aided by such remedies as assist the action of the biliary system. Salt acts in this way, and thus salt mashes are good: salt may also be given in the trough, to be licked at will by the sheep.

Rot. In timber. [Dry Rot.]

Rota (Ital.). An ecclesiastical court at Rome, consisting of twelve prelates. It takes cognisance of all suits by appeal, and of all matters, beneficiary and patrimonial.

Rotation (Lat. rotatio, from rota, *a wheel*). In Mechanics, the motion of a solid body about an axis. In the article Pendulum, the rotation of a body under the action of accelerating forces has already been considered. In that article reference was made to the purely kinematical part of the question, and it was shown how rotations can be combined and resolved. It will be sufficient here, therefore, to add a few words with respect to the dynamical part of the subject, and to consider briefly, 1. The rotation of a body about a fixed axis produced by any instantaneous forces; 2. The effect of such forces when only one point of the body is fixed; and 3. Their effect on a body free to move in any direction whatever. In doing so we shall merely transcribe the more important results developed with such marvellous perspicuity by Poinsot in his *Théorie Nouvelle de la Rotation des Corps*, Paris 1852.

1. The instantaneous forces acting on the body capable of rotating around a fixed axis oz may always be resolved into a single force R, passing through o and inclined at an angle a to oz, and a single couple G, whose axis, which we may suppose also to pass through o, is inclined at an angle ϕ to the axis of rotation. The latter, therefore, will receive two percussions, one R cos a in the direction of its length, the other R sin a perpendicular thereto. These will be sustained by the fixed supports, and will be without effect on the subsequent rotation of the body, as will also the component G sin ϕ of the couple, the plane of which contains the axis. The only effective part of the forces, therefore, will be the component couple G cos ϕ, acting in a plane perpendicular to the axis; it

will cause the body to rotate with an angular velocity θ equal to the quotient of its own moment, G cos ϕ, by the moment of inertia $\int r^2 dm$ with respect to the axis of rotation. Unless the latter, however, be a central principal axis, a momentary percussion will be produced on it by this *couple of impulsion* G cos ϕ itself; this percussion will be due to a force

$$P' = -\theta\sqrt{(\int x\,dm)^2 + (\int y\,dm)^2},$$

applied at o perpendicularly to the axis, and vanishing only when the latter passes through the centre of gravity, and to a couple whose plane contains the axis and whose moment is expressed by

$$K' = -\theta\sqrt{(\int xz\,dm)^2 + (\int yz\,dm)^2}$$

and consequently vanishes only when the axis of rotation is a principal axis of the body. These several percussions being destroyed by the fixed axis, the body will commence its rotation around the latter *freely*, as around a *spontaneous* axis, and by so doing give rise to centrifugal forces which, unless the axis be a central principal axis, will produce a permanent strain upon it during the whole course of the motion. The components of the strain are a force $-P'\theta$, perpendicular to the axis through o, whose line of action turns with the body, and a couple $-K'\theta$ acting in a plane which turns with the body and passes through the fixed axis.

2. The effect of instantaneous forces on a body capable of moving about a fixed point o is somewhat more complicated. Such forces may always be resolved into a single one acting at o, and therefore destroyed, and to a single *couple of impulsion* whose plane, or one parallel to it, is called the *invariable plane*, from the fact that if, at any period of the body's motion, the forces which animate its several particles be resolved, the same couple of impulsion will be obtained.

To form a conception of the motion of the body, let the Momental Ellipsoid corresponding to the point o be constructed. The instantaneous axis of rotation will pierce this ellipsoid in a point I, the *instantaneous pole*, at which the tangent plane is parallel to the invariable plane. If this tangent plane be fixed and the ellipsoid be made to roll on it without sliding, so as to carry with it the whole body, the motion of the latter will be precisely imitated, at least so far as the successive positions in space are concerned. To render the representation dynamically perfect, it is only necessary to make the ellipsoid roll so that the angular velocity about the instantaneous axis o I shall be proportional to the length of the latter. The locus of the pole I on the ellipsoid is called the Polhode; and the curve which it traces on the fixed plane, the Herpolhode.

Euler's equations of the motion of a body around a fixed point may now be easily interpreted. If A, B, C, be the principal moments of inertia, and, at the instant under consideration, p, q, r, be the resolved parts, along the principal axes, of the angular velocity about the instantaneous axis, these equations are:

$$A\frac{dp}{dt} = (B - C)\,qr,\quad B\frac{dq}{dt} = (C - A)\,rp,$$

$$C\frac{dr}{dt} = (A - B)\,pq.$$

(Euler's *Theoria Motus Corporum Solidorum*, 1765.)

3. The effect of instantaneous forces on a perfectly free body may now be easily conceived. Such forces are equivalent to a single force, applied at the centre of gravity, which imparts to the whole body a purely translatory motion, and to a single couple whose effect has been already described.

4. The equations of the motion of a body about a fixed point under the action of accelerating forces are—

$$A\frac{dp}{dt} - (B - C)\,qr = L,$$

$$B\frac{dq}{dt} - (C - A)\,rp = M,$$

$$C\frac{dr}{dt} - (A - B)\,pq = N,$$

where L, M, N are the moments, relative to the principal axis, of the impressed forces acting at the instant under consideration. To these equations must be added three others, which define the positions, relative to axes fixed in space, of the principal axis of the body at the time under consideration. Except in a few special cases these equations have not been integrated. (Poisson's *Mécanique*; Price's *Infinitesimal Calculus*, vol. iv. &c.)

Rotation of Crops. In Agriculture and Gardening, it is found that the same annual crop cannot be advantageously cultivated on the same soil for more than one or two years; and hence one kind of crop is made to succeed another. The number of cultivated crops being limited, when the whole course has been gone through once, the series is again repeated; and hence the use of the word *rotation*. As the same kinds of crops are not, however, always grown in regular succession, a change being frequently made according to general principles, the term used in that case is *succession of crops*. The principle on which the succession of crops is founded is, that every kind of plant extracts nourishment from the soil, and leaves it deficient of that which should prove nutritious to another species. As a general principle of guidance in determining the succession of crops, it is considered advantageous that a crop cultivated for its leaves or roots should succeed one cultivated for its ripened seeds; that the cereal grasses should be succeeded by leguminous plants; taprooted plants, or plants bearing tubers, by fibrous-rooted plants; plants which form a compact covering on the surface, such as corn and legumes sown

broadcast, by plants which only partially cover the surface, such as crops grown in rows sufficiently wide to admit of cultivation between; and plants which may be said by their abundant leaf to feed the soil with what they take from the air, by plants which are almost wholly dependent upon the stores of food for them contained in the soil and subsoil. It may also be adopted as a rule, that where land is to be subjected to a crop of the same plants for a number of years, as in permanent pasture, the plants composing the crop should be of several different kinds, seeking a different kind of aliment. Hence the propriety of sowing clover, ribwort, and other taprooted dicotyledonous herbage plants among pasture grasses.

Rotations, Composition and Resolution of. In Kinematics, the transformation of a given system of rotations to another equivalent system. A rotation, like a force, may be represented perfectly by a right line of definite direction and length. The direction must coincide with that of the rotation-axis, and the length be made proportional to the angular velocity. Poinsot has shown (*Théorie de la Rotation des Corps*) that these line-representatives of rotations may be combined according to precisely the same laws as those of forces. [FORCES.] Thus the resultant of any number of coaxal rotations has the same rotation-axis as the components, and an angular velocity equal to the algebraical sum of the angular velocities of the components; and again, the diagonal of a parallelogram represents, fully, the resultant of the rotations similarly represented by its two conterminous sides. Further, two equal and opposite rotations around parallel axes constitute a *couple of rotations*, and are equivalent to a translation of the whole body perpendicular to the plane of the couple, with a velocity equal to its *moment*, i.e. to the product of either of the equal angular velocities into the *arm of the couple* or distance between the parallel axes. [COUPLE OF ROTATIONS.] This being the case, we are led to the following important results. Every system of rotations impressed upon a body is equivalent to a single rotation around an axis passing through any point o, and to a translation of the whole body in a direction inclined to that axis. The magnitude R of this resultant rotation as well as the direction of its axis are invariable, but the magnitude and direction of the translation vary in general with the position of the assumed origin o. By removing the point o to a certain point A in the line oA perpendicular to the above axes of translation and rotation such that $oA = \frac{G \sin \phi}{R}$, where ϕ is the angle between the two axes, the whole system is reduced to a rotation R around a parallel axis through A, and a translation in the direction of this axis whose velocity is expressed by $G \cos \phi$. This new axis is called, as before [FORCES, COMPOSITION AND RESOLUTION OF], the *central axis*; or when the motion of the body at the moment is considered, the *instantaneous sliding axis*, since at that moment the motion in question may be regarded as composed of a rotation about the axis along which the body simultaneously slides; in short, as a screw-like motion. The given system of rotations may also be reduced to two rotations around axes which do not intersect, and that in an infinite variety of ways. Any two such axes are called *reciprocal* or *conjugate lines*, and possess remarkable properties, for a full statement of which the reader must be referred to the investigations of Poinsot, Chasles, Lamarle, and others. [KINEMATICS.] The line upon which the shortest distance between two conjugate lines is measured always meets the central axis perpendicularly, and there are innumerable conjugate axes at right angles to each other.

In order that a body may remain in equilibrium under any system of impressed rotations, the resultant rotation and translation R and G at every point o must each vanish. If R alone vanish, the whole motion will resolve itself into one of translation. If the body have a fixed point o, its motion will consist of a rotation around an axis through that point whose position in the body as well as in space will vary every instant. Such an axis is called an *instantaneous axis*, and the clearest image of the body's motion is obtained by conceiving a cone, attached to the body, to roll upon another cone fixed in space; both cones having the fixed point o for vertex. The common generator of the two cones at any moment is the instantaneous axis of the body.

Rotatories. Wheel animalcules. [ROTIFERS.]

Rothoffite. A variety of common iron-Garnet from Längsbanshytta in Sweden, containing a large quantity of protoxide of manganese.

Rotifera (Lat. rota, *a wheel*, and fero, *I carry*). The name of a class of highly organised Infusorial animals, of the articulate type, outwardly distinguished by certain ciliated appendages at the anterior part of the body, which seem to move in a rapid rotatory manner, and by their superior size. They are commonly termed *wheel animalcules*.

Rotten Stone or **Tripoli.** The name given to certain natural earths, consisting of silica in an extremely fine state of division, and in a state adapted to polish without scratching the surface of glass, metals, &c. These vary greatly; chiefly, however, in the mechanical state in which the silica exists. *Trent sand* or *wharpe*, a river sand used for bringing German silver and other alloys to a surface, is a sharp sand obtained from the river Trent, and consists chiefly of infusorial animalcules. Bath brick is nearly the same in its origin. The *polir schiefer* of Germany and the powder from Bilin are also of the same kind. There is in these an admixture of carbon, and occasionally a little resinous organic matter. *Rotten stone*, either Welsh or from Derbyshire (near Bakewell), is a lighter and more friable

material of very fine grain, and is now used for silver and the finer class of goods. It is found among the carboniferous limestone in seams between two masses of limestone, and of small thickness. *Tripoli* is the name applied to the earthy varieties in which the silica is nearly pure and the particles very minute. Lime is sometimes used instead of the silica powder, and powdered hæmatite or some other form of peroxide of iron is the chief polishing material used in glass-making, but the true rotten stone is always silicious, and consists of silica in an extremely minute state of division, whether derived from the animal, vegetable, or mineral kingdom.

Rottlera (after Dr. Rottler, a Dutch missionary and naturalist). A genus of small Euphorbiaceous trees found in tropical Asia and Australia. The most interesting is *R. tinctoria*, a common Indian bush, from the surface of whose capsules, which are about the size of peas, a red mealy powder is obtained, well known in India as Kámalá, and much used by Hindu silk-dyers, who obtain from it, according to Roxburgh, a deep bright durable orange or flame colour of great beauty. This is obtained by boiling the powder in a solution of carbonate of soda. The root of the tree is also said to be used in dyeing. The Kámalá appears also, according to Mr. Hanbury, to be used in cutaneous complaints. Among the Arabs of Aden it is given internally in leprosy, and used in solution to remove freckles and pustules; in this country it has been used successfully in treating the eruption known as wildfire on children, by rubbing the powder over the affected part with moist lint. It appears, however, to be most valued as an anthelmintic, and has been extensively used with much success in India by various medical men, in cases of tapeworm.

Roturier. In French History, the political antithesis to the noble. Not only were the nobles invested with certain personal immunities and privileges in France, but they were relieved of the *taille*, an oppressive property tax, which fell on the lower classes exclusively. The wrongs inflicted on the roturier or peasant were described by Arthur Young; and it cannot be doubted that the remembrance of these wrongs increased, if indeed it did not originate, the bitterness of parties during the revolutionary era. The name *roturier* is very ancient, and was early used in a contemptuous sense. (Hallam, *Middle Ages*, chap. ii. part ii.)

Rouble (Russ. rublyn). A Russian silver coin of different values. It was first struck at Moscow in 1654. Catherine II. caused some gold coins to be struck with this name; but they are no longer current. The silver standard has been established since 1839 as the lawful money of account and exchange in Russia, and is valued at par at a little over 3*s.* 1½*d.* There is, however, a paper rouble called *banco*, which circulates at two-sevenths of the silver rouble. Hence the banco rouble is equal to 10⅝*d.* sterling. For a valuable account of the Russian paper money, see Tooke's *History of Prices*, vol. iv. pp. 209 sqq. [MONEY.]

Roué (Fr. literally *one broken on the wheel*, the punishment of the highest crimes in France before the Revolution). In the beau monde, a person devoted to a life of pleasure and sensuality, but not so completely vitiated in his character and manners as to be excluded from society. The term is said to have been first used in this sense by Philip of Orleans, the regent of France.

Rouge (Fr.). A species of lake prepared from the dried flowers of the *Carthamus tinctorius*, or safflower. The term *rouge* is also applied to finely levigated *colcothar*, or peroxide of iron, used for polishing.

Rough Cast. In Architecture, the plastering of walls with mortar and fine gravel, or when the rendering coat is roughened by means of a stiff broom, without any subsequent rendering to produce a smooth surface.

Rough Coal. A name for SPLINT COAL.

Rough Stucco. In Architecture, stucco floated and trowelled in a small degree with water.

Rough-tree Rail. In a ship, the horizontal timber or plank forming the top of the bulwarks. It rests on the heads of the several ribs or timbers, and at the same time caps both the external and internal planking.

Roughing In. [RENDERED AND SET.]

Roulette (Fr.). The curve traced by any point in the plane of a given curve when the latter rolls, without sliding, over another fixed curve. A similar definition applies to surfaces. Roulettes include a great number of well-known curves, amongst which are epitrochoids, hypotrochoids, epicycloids, hypocycloids, the common and curtate cycloids, involutes, &c. Pedal curves may also be regarded as roulettes. In fact, if the fixed and rolling curves were precisely equal and, without coinciding, touched each other at corresponding points, any point in the plane of the rolling curve would describe a curve similar to the pedal of the fixed curve with respect to the corresponding point in its plane. An interesting memoir on roulettes by Prof. Maxwell will be found in the *Cambridge Phil. Trans.* for 1849. The normal, and consequently also the tangent at any point of a roulette can be easily constructed. In fact, at any instant the rolling curve may be considered as rotating around its point of contact with the fixed one, so that the element at a point m of the roulette must be perpendicular to the line $o\,m$, in other words $o\,m$ is the normal at m. The radius of curvature ρ of the roulette at m can also be found by very simple considerations. If ρ_1 and ρ' denote the radii of curvature of the fixed and rolling curves at their point of contact o, then,

$$\frac{om}{\rho} = 1 - \frac{\cos\phi}{\frac{om}{\rho_1} + \frac{on}{\rho'}}$$

where ϕ is the angle between the normals to the roulette and to the fixed curve. (Liouville's *Journal*, t. x.) Mr. Stubbs, in vol. i. *Trans. Dublin Phil. Soc.*, has given a general method of finding the area of a roulette.

Round (Fr. rond, Lat. rotundus). The property of a circle, sphere, or right cylinder, and indeed of any solid of revolution, though most commonly confined to the sphere and cylinder. French writers term all bodies enclosed by surfaces of revolution *corps ronds*.

Round Robin (Fr. rond ruban). A phrase originally derived from a custom of the French officers, who on signing a remonstrance to their superiors wrote their names in a circular form, so that it might be impossible to ascertain who had headed the list. It is now used to signify any act by which a number of men bind themselves to pursue a certain line of conduct.

Round Shot. In Artillery, spheres of cast iron or steel.

Round Table of King Arthur, The. According to the legendary accounts, this mythical sovereign instituted a company of twenty-four (or according to others twelve) of his principal knights, bound on certain solemn days to appear at his court, and meet round the table whence their common title was derived. The famous table (of unknown date, but comparatively very modern) still to be seen in the shire hall at Winchester illustrates this celebrated fiction. The rhyming chronicle *Brut of England*, composed or continued by Master Wace (A. D. 1155), is considered by antiquaries as the source whence the popular romances concerning Arthur and his knights were first derived. The myths of King Arthur are given gravely as history in the chronicle of Jeffrey of Monmouth. (*The Romance of Sir Tristram*, edited by Sir Walter Scott; Milman, *History of Latin Christianity*, book xiv. ch. vi.; Lappenberg, *England under the Anglo-Saxon Kings* i. 101.) [Roland; Sigurdr.]

Roundel. In Heraldry, an ordinary in the form of a circle. It is improper to say a roundel or, gules, &c., describing it by its tincture; unless, first, in case of counter-changes; secondly, where the roundel is of fur, or of equal tinctures, as a roundel ermine, a roundel checky of or and azure, &c.; otherwise, roundels have distinguishing names, according to their tinctures. A roundel or is called a *bezant*, from the gold coins of the Greek or Byzantine empire; a roundel argent, *a plate*; gules, a *torteau*, a kind of cake; azure, *hurt*, a species of flower; vert, *pomme*; sable, *pellet*; purpure, *golpe*. A field or charge, with equidistant roundels, is said to be *bezanty*, *platy*, &c., according to the tincture.

Roundelay. In Poetry. [Rondeau.]

Roundheads. A nickname given to the Puritans, at the time of the civil wars, by the Cavaliers, from the close black skull-cap, reaching down to the ears, which was then worn by staid and serious persons; or, more probably, from their custom of wearing the hair closely cut to the head.

Roup. A Scotticism for *auction*.

Rout. [Riot.]

Route (Fr. feuille de route). In Military language, the document conveying to troops an order to move from one place to another.

Route, Commercial. It seldom happens that any one country possesses such an area, with such a variety of soil, of climate, of mineral wealth, of geological formations, as will enable it to supply itself with all the conveniences of life within its own boundaries. However various may be its products, however copious its resources, it can very rarely make itself independent of the rest of the world (if indeed it ever could do so) without inducing not only great moral and political inconveniences, but great economical loss. Some countries approximate to this condition, or have been isolated for reasons chiefly political. Thus, perhaps, up to the middle of the thirteenth century, there was little or no communication between China and the rest of the world, the resources of that vast country enabling it to subsist, and develope a peculiar kind of civilisation, apart from any intercourse with the rest of mankind. Thus, also, it appears that the monarchies of Mexico and Peru, discovered by the Spanish navigators, lived in absolute insulation. Till within late years, the intercourse of the Japanese with any other country was almost prohibited. In all these cases, however, though a considerable developement of economical arts has been achieved, the social condition has been lower and the conveniences possessed by the people far below those which might have been procured by intercourse with other nations.

The agencies of foreign trade have been induced by two causes. Communities, from the want either of certain utilities or objects of enjoyment, which could not be produced in the area of their own country, have been eager to procure these benefits, by acts of exchange, from other countries in which they were plentifully produced, or they have made themselves the carriers between nations and distributed the products of one in exchange for the products of another. Both these operations were exhibited in the history of ancient commerce. The Greeks, it seems, produced in order to exchange. Athens, for instance, had mines and manufactories, and exchanged the articles which she produced, against the grain and other raw material of the regions which lay near the rivers and on the east of the Black Sea; while Carthage, like the rest of the Semitic colonies, was chiefly engaged in the carrying trade, between the remotest East and West on the one hand, and the area of the Mediterranean on the other.

Among these ancient commercial routes, one of the earliest is that by which the produce of the farthest East was conveyed by coasting along the southern coast of Asia to the ancient ports of the Red Sea. By this, and probably by an overland route as well, the exotic treasures and curiosities which Solomon gathered,

were imported into Palestine. Similarly, it is clear that the ethnological notices contained in the history of Herodotus were obtained from and indicate the march of caravans, by the northern route of the plateau of Central Asia, over the Caucasus to the ports of the Black Sea, by the Danube to the western extremity of Gaul, perhaps of Spain, as well as through the tribes which occupied the territory lying below the southern shore of the Mediterranean. Intercourse with the Eastern world was, however, checked rather than developed by the growth of the Roman empire, and it is probable that at or about the commencement of our era, commerce with the East was narrower than in the days of Herodotus, still less than that in the time of Alexander. Rome destroyed Carthage, but did not inherit her spirit of commercial enterprise.

After the irruption of the barbarians, and the downfall of the Western Empire, the commerce of Christendom with the East passed chiefly through Constantinople, the communication between the Mohammedan kingdoms being occasionally regular, though more frequently interrupted. A new era commenced with the injury inflicted on the empire of the East by the Latin conquest, and the rise of the commercial republics of Italy. These commercial republics, such as Venice, Genoa, and Florence, owed some of their riches to manufacture, but more to the carrying trade; and very exact information, considering the times, may be obtained as to the course of traffic. Towards the close of the thirteenth century, Marco Polo published his travels, in which he recounts his observations, in the course of his journeyings from Venice to the extreme verge of Eastern China. But the best accounts given of the trade of Venice and Florence, in the beginning of the fourteenth century, are found in the works of Sanuto and Balducci, the former a Venetian, the latter a Florentine.

Marino Sanuto Torcellus was a Venetian senator, who composed a work in the year 1321 (entitled *Secreta Fidelium Crucis*, and printed in a collection of historical documents, under the name of *Gesta Dei per Francos*), addressing his statements to Pope John XXI. The immediate purpose of this work is to insist on the danger which menaced Europe from the great power of the sultan of Egypt, and to point out the means, partly commercial, partly military, by which the danger might be averted. In explanation of his plan, he gives a statement of the routes by which Eastern produce was imported into Europe.

This produce was collected at two ports, Malabar and Cambeth, the latter being probably Ceylon, and thence shipped to four other ports, Hormus, Kis, the river below Baldac (i.e. Bagdad), and Aden. The earlier, and, to judge from the price of commodities, the cheaper route, was that from Bagdad up the Tigris, and through Azerbijan to Seleucia, then called Licia, and Antioch. But this road had been interrupted or rendered unsafe by the political events which have ultimately reduced the most fertile and once most prosperous parts of Central Asia to a desert. The chief course lay by Aden, up the Red Sea, across the eastern desert of Egypt, to Chus on the Nile, and thence to Alexandria. Sanuto's plan among other details suggests that an ancient route through Armenia to Trebizond might be restored. This route Sanuto informs us that he had traversed five times in person. It is singular that there seems to have been more easy access to mid-Asia in that time than there is now. This Christian merchant visited, apparently with no extraordinary risk, certainly with the means of successful traffic, regions which cannot be entered now, except in the most cautious manner. How dangerous it is to enter Bokhara, which was passed by Sanuto, may be seen from the travels of Wolff and Vambéry.

Balducci refers to another road, lying to the north of those specified by Sanuto, which passed from China to the Caspian, and thence by the Don to the Black Sea. Some of these caravans were, no doubt, directed to Novgorod and Moscow.

Distinct, but contemporaneous with this trade to Egypt, was that carried on by the Hanseatic League, the origin and history of which have been commented on by the learned and laborious Lappenberg. This famous league, founded for mutual defence, and equally important for the purpose of establishing a uniform mercantile system, drew to itself nearly all the trade of North-eastern Europe, and actually established communications with North America. This intercourse came to a violent end, in the great physical events which accompanied the plague of 1348, the effect of which was to raise a barrier of ice round Greenland, and to make intercourse with Iceland difficult and dangerous. It is probable that other commercial routes existed, but these were by far the most important.

The stimulant of the caravan and Red Sea trade was the demand for spices, the craving for which among the Western nations was the more urgent, as the imperfect agriculture of the time made the winter diet of our forefathers unpalatable and unwholesome. The cost of these articles was very great; pepper, the commonest of them, being worth in England, on the lowest estimate of ancient money, not less than 8*s.* the pound troy before the great plague, and double that price afterwards. According to the *Forme of Cury* (a treatise on cookery written in the reign of Richard II. by or for the king's cooks), pepper, as in the story of the *Arabian Nights*, was used in confectionery.

The exchange was effected by metals, and particularly by silver. From the remotest ages, India and China have absorbed the metallic produce of the Western world. Mines in these regions have either been scanty, or have not been worked successfully. The necessity of exporting silver to the East in exchange for its produce first broke down that ancient

commercial superstition, that the wealth of a country consists in the gold and silver which it possesses. That India has not been flooded with silver, in spite of this continuous importation, is due to bad government, which, compelling the people to resort to hoarding, has indirectly, by a reverse process to that of mining, consigned again to the earth the treasure which labour in other regions had collected and transported to the Indian peninsula.

It is hardly necessary to say, that the political greatness of Italy during the middle ages was due to the monopoly of the carrying trade. The almost simultaneous discovery of the American continent in 1492, and of the Cape passage in 1497, by Columbus and Vasco de Gama, completely altered the relations in which Italy stood to Europe, by drying up the channels through which Eastern wealth had previously flowed. For a while the great republics of Venice and Genoa lived on the past—lived, as economists might say, on their capital; and so enduring was the recollection of their former commercial greatness, that it fell utterly only at the first shock of the revolutionary army of France.

Meanwhile, there was a short period during which Portugal took a great place in the commercial world. For a while it seemed possible that the victories of Albuquerque, and the preaching of Francis Xavier, might create a lasting empire. But this strange mixture of commercial enterprise and religious fanaticism was radically weak when it seemed strongest, and the long sea passage was slowly appropriated by the Dutch and the English.

The discovery of the New World was followed by the Spanish conquests. The vast empire which the Spanish monarch administered in the sixteenth century, overshadowed and dismayed the rest of Europe. But the occupation of Mexico, and much of the southern continent, was from the beginning not commerce, but rapine. After destroying the ancient monarchies of the New World, and pillaging their treasuries, the Spaniards exterminated the ancient inhabitants by compulsory labour in the mines, and at the instance of Las Casas, who saw in such an expedient the only means of saving the relics of the ancient races, introduced negro slavery into America. In order, however, to bind their colonies more closely to Spain, and secure their dependence, it was the settled policy of the court of Madrid, that no person of Indian or mixed blood, and not even anyone of pure Spanish descent, born in the New World, should be occupied in any public office. (Lecky, *Rise and Influence of Rationalism in Europe*, ch. vi.)

It was impossible that from such a system any true commercial energy should be developed. It was unlikely, after these colonies were emancipated, that they should emerge from so long a political nonage into the possession of such faculties as are needed for the social advancement of communities. The resources of the New World were wasted by the Spanish occupation. But if the economy of the Spanish colonies had been ever so prudent, it may be doubted whether, in the face of the political events which occurred in Spain at and after the commencement of the sixteenth century, events whose effect became yearly more destructive to the national character, the necessary spirit of commercial enterprise could have survived the utter annihilation of religious and civil liberty. Anyone who compares the constitution enjoyed both by Castile and Aragon in the middle ages with the tyranny of Charles and Philip, can see sufficient reason to account for the decline of Spain. Not but that its strength survived its wealth and real prosperity. Impoverished as it was by the resistance of the Netherlands, the final blow to the ascendency of Spain was given in Van Tromp's defeat of the Spanish Armada in the year 1639. Long before this date, however, the Dutch had crippled Spain in her Transatlantic and Asiatic settlements; and though the English government was unfriendly to the Dutch, it was a general principle that there was no peace with Spain beyond the line.

It would be impossible within the limits of this article to give any exact account of the various commercial routes in our own day. The reader may be referred to Maury's *Physical Geography of the Sea* for much valuable information as to the effect of those discoveries which navigators have made on the course of trade. One of these discoveries may be adverted to. In 1775, Franklin found out the nature and course of the Gulf Stream, but for political reasons kept the fact a secret till after the acknowledgement of American independence. There was great reason for this secrecy, since, if the real effect of the discovery had been known, it is probable that the Southern states of the American Union would not have exhibited so much sympathy with the national cause. Before the time in which the knowledge of this current was possessed, the northern ports of the American plantations were inaccessible in the winter months, and the chief port was Charleston. But after the nature of the Gulf Stream was known, the greater part of the trade was diverted to the northern ports, and New York and Philadelphia became the chief cities of the Union.

It will be a singular circumstance, if in our day the dream of the Pharaohs and Ptolemies should be realised, the Red Sea and the Suez canal again become the highway for Eastern trade, and those parts of the Mediterranean whose greatness has passed away by the use of the long sea passage be again revived as centres of commercial activity.

Rowan-tree (Norse runa, *a charm*). A Scottish name for the *Pyrus Aucuparia*. 'The most approved charm against cantraps and spells,' says Jamieson, 'was a branch of the Rowan-tree planted and placed over the byre. This sacred tree cannot be removed by unholy fingers.' Johnston also observes,

'Roan-tree and red thread
Haud the witches a' in dread.'

Rûn-stafas were mysterious staves; and from this last use of the word, the name *rûn* came naturally to be applied to the tree from which such staves were usually cut, though why this tree should have been so exclusively used for carving runes upon as to have thence derived its name, not only in Britain, but also in Scandinavia, does not appear to be ascertained. (Prior, *Popular Names of British Plants.*)

Rowing. The propulsion of a boat by oars. Rowing is reckoned the most favourable application of human strength for obtaining motion in the water; but the whole force is not effective on the oar, as the part of the oar's blade in the water, but inside the actual fulcrum, which is at its point, is held back by the resistance of the fluid. In rowing, the power is applied at the handle of the oar, and the weight of the boat is encountered at the rowlock. The rower sits *before* his oar, with his back to the boat's bow, and in taking his stroke supplements the strength of his arm with the weight of his body thrown backwards towards the bow. Some nations take short strokes, which they rise up in making; the English prefer a long stroke sitting.

ROWING. In the service of ordnance, the same as *pinching*. [PINCHING.]

Rowlock. The apparatus on the side of a boat for keeping the pressure of the oar constantly at one point. In different parts of England various devices are practised for this end. At sea, the commonest plan is to have two short wooden uprights projecting from the gunwale, between which the oar is restrained. On the Thames these are aided by a button on the oar, to prevent too great a length passing overboard. On the south coast an iron stirrup sustains the oar and pivots in the gunwale. On the east coast of England an iron pin is fixed in the gunwale, and the oar fastened to it by a leathern thong. In the north-west counties a similar pin passes through the oar itself, which precludes feathering altogether. The last two systems are dangerous, from the impossibility of shipping the oars in case of sudden emergency; while, on the other hand, they lessen the probability of losing them.

Roxburghiaceæ (Roxburghia, the only genus). A small natural order of Dictyogens, distinguished by having bisexual flowers, and solitary simple many-seeded carpels, with long-stalked anatropal seeds, and a basal placenta. The few species referred to the genus *Roxburghia*, which constitute this group, are chiefly of botanical interest.

Royal. In Naval affairs, the sail and mast above the top-gallant sail and top-gallant mast respectively.

Royal Oak. *Robur Carolinum.* In Astronomy, a constellation formed by Halley, in the southern hemisphere. [CONSTELLATION.]

Ruay. The name given to certain weights used in India, consisting of the seeds of *Abrus precatorius* and *Adenanthera pavonina*, the former being called Small Ruay, and the latter Large Ruay weights.

Rubace or Rubasse. Names given by French lapidaries and jewellers to a variety of Rock Crystal traversed by rose-coloured cracks. For further details, see Bristow's *Glossary of Mineralogy*, p. 324.

Rubble. A quarryman's term for the inferior varieties of stone surmounting each valuable bed of limestone extracted for building purposes. It is often the result of weathering or natural disintegration by air and water, sun and frost. The fragmentary masses often found between a rock and the overlying soil derived from the rock, are also sometimes called by this name. It is an equivalent of the term BRASH, used in some parts of England. Thus *cornbrash* is a brash or rubble of rotten limestone making a good corn land. Almost all quarries of limestone abound with this kind of substance.

The term is also applied to any stone broken from the quarry in rough irregular masses, and not subjected to any further dressing; stone reduced to a rectangular form being called ASHLAR.

Rubefacients (Lat. rubefacio, *I make red*). Substances which, when applied to or rubbed upon the skin, induce a redness or blush upon the part, not followed by blister.

Rubellane. An altered Biotite found in small, reddish-brown, hexagonal tables in Saxony, and at Schima in Bohemia.

Rubellite. Red Tourmaline containing a considerable proportion of manganese, to which it owes its colour. It generally occurs in closely aggregated crystals, varying in colour from a slight tinge of red to a fine pink. It is found in Ireland at Ox Mountain near Sligo, but the finest specimens are brought from Siberia, Moravia, and Paris in the State of Maine in North America. There is a magnificent group of crystallised Rubellite in the British Museum, from the cabinet of the late Mr. Greville, which was presented to Colonel Symes by the king of Ava, and which has been valued at 1,000*l*.

Rubenglimmer. The German name for a variety of Göthite of a hyacinth-red colour.

Rubeola (Lat. rubeo, *to grow red*). [MEASLES.]

Rubezahl. The name of a famous spirit of the Riesengebirge in Germany, who is celebrated in innumerable sagas, ballads, and tales, and represented under the various forms of miner, hunter, monk, dwarf, giant, &c. He answers to the English PUCK, and is said to aid the poor and oppressed, showing benighted wanderers their road, but waging incessant war with the proud and wicked. The origin of the name is obscure. (*Tales of Musæus.*)

Rubia (Lat. ruber, *red*). A genus of the *Galiaceæ*, an order closely allied to *Cinchonaceæ* (*Rubiaceæ*), and by many considered as a subdivision of that order. This genus furnishes the dye called Madder, which is the dried root of *Rubia tinctorum*. In the living roots the colouring matter is yellow, but it becomes red on drying. The best madder is imported from the

Levant, but some comes from Holland and France; the dye is much used in the latter country under the name of *Garance*. Some of the Indian species also yield a red dye. Madder has been stated to possess medicinal virtues; these, however, are so slight as to be now disregarded. The bones of young animals fed on madder become tinged with a red colour, and physiologists avail themselves of this fact in their researches on the mode of growth of bones. The stem and leaves of *R. tinctorum* are used in France for polishing metal-work, for which purpose their stiff hairs adapt them. The leaves and herbage also are used as fodder for animals.

Rubiaceæ. [CINCHONACEÆ.]

Rubian. An intensely bitter amorphous yellow substance, deposited on evaporating the alcoholic solution of the dried aqueous extract of madder. [MADDER.]

Rubicel or **Rubicelle.** A term applied to the Brazilian Ruby, and also to the yellowish or orange-red varieties of Spinel.

Rubinic Acid. *Rufocatechuic acid.* An acid formed by exposing a solution of catechuic acid in carbonate of potassa to the action of air.

Rubric (Lat. rubrica, as being originally written with red earth). In the language of the old copies of manuscripts, and of modern printers, any writing or printing in red ink. The date and place on a title-page being frequently in red ink, the word *rubric* has come to signify the false name of a place on a title-page. Many books printed at Paris bear the *rubric* of Genoa, London, &c. But the most common use of the word is in ecclesiastical matters. In MS. missals, the directions prefixed to the several prayers and offices were written or printed in red ink; and hence the *rubric* familiarly signifies the order of the liturgy, in Roman Catholic countries as well as in England.

Rubsen Cake. A kind of oil-cake made on the Continent, from the seeds of *Brassica præcox*.

Rubus (Lat. *a bramble-bush*). A familiar genus of *Rosaceæ*, to which are referred several of our common fruits, as the Raspberry, Blackberry, Dewberry, &c. The species are mostly shrubs, trailing or erect, having prickly stems, pinnate, quinate, ternate, or simply lobed leaves, and edible fruit. They are very well represented by the Bramble of our hedgerows, and the Raspberry of our gardens.

Ruby (Fr. rubis, Ital. rubino, from Lat. ruber, *red*). A term which, in strictness of speech, should be restricted to the *Oriental Ruby*, or to the red varieties of SAPPHIRE. Among lapidaries, however, the name Ruby is applied to several stones, of very different chemical composition, which they distinguish by their colours. Thus the scarlet coloured is called *Spinelle Ruby*; the pale or rose-red, *Balais* or *Balass Ruby*; the yellowish-red, *Rubicelle*; and those of a decided orange-red, *Vermeil* or *Vermeille*. The finest stones are found in the sand of rivers in Ceylon, in the Capelan mountains of Pegu, and in Ava. The Ruby, as a precious stone, ranks next to the diamond in value; in fact, a very fine ruby, of a carat or upwards, is more valuable than a diamond of the same weight. [STARSTONE.]

RUBY. In Printing, a kind of type two and a half sizes smaller than that used in this work. [TYPE.]

Ruby Silver. [PYRARGYRITE.]

Ruby Wood. One of the names under which Red Saunders wood, the timber of *Pterocarpus santalinus*, is known.

Rudder (Ger. ruder). A heavy flat piece or frame of wood, hung upon the stern post by means of pintles and gudgeons, for the purpose of steering the ship. The rudder is turned round the stern post as an axis, by the tiller, which enters the rudder head. In vessels drawing much water the rudder is deep and narrow; in flat-bottomed vessels, it is shallow and broad. When carried to a considerable breadth, as in the Chinese vessels, it is pierced with holes, which preserves an increased leverage with a diminished direct resistance from the water.

The action of the rudder may be thus explained. While it remains in line with the keel, the force of the water gliding past the deadwood or narrow portion of the stern is equal on both sides of the rudder, and equilibrium is maintained; but if the rudder be forced to one side, the pressure is taken off on the opposite side, while from acting at a less angle the water exercises an increased pressure on the side to which the rudder is turned. The effect is to force the stern round on the centre of gravity as a pivot, the ship's head, of course, turning to the same side as that on which the rudder is. When the head has sufficiently deviated from its former line, the rudder is permitted to resume its straight position. In sailing on a wind, the rudder is kept permanently on one side to counteract the tendency to make leeway.

Rudder Chains and Pendants. Short lengths of chain ending in ropes, for preventing the loss of a rudder in the event of its being unshipped in a heavy sea. The chains are shackled to the rudder by a bolt, in the back of it, just above the water-line, and the rope pendants are made fast to bolts in the stern quarters.

Ruddle. [REDDLE.]

Rudenture (Fr. from Lat. rudens, *a rope*). In Architecture, the rope, or staff, with which the lower parts of the flutings of columns are often filled. [CABLINGS.]

Rudiarius (Lat.). The term applied to a discharged gladiator. The word is derived from the staff (*rudis*) which was given him in token of his dismission. (Horace, *Ep.* i. 1, 2.)

Rudistæ. [HIPPURITES.]

Rudolphine Tables. A set of astronomical tables computed by Kepler, and founded on the observations of Tycho Brahe. They were called the *Rudolphine Tables* in honour of Rudolph II., emperor of Bohemia, who, upon the death of Tycho in 1601, conferred upon

Kepler the title of imperial mathematician, and undertook to defray the expenses of their preparation. Owing to various causes the work was not completed until 1627, when the tables were published at Ulm. They are the first that were ever calculated on the hypothesis that the planets move in elliptic orbits, and they contributed greatly to the progress of modern astronomy. For a detailed account of this very remarkable production, see Delambre, *Astronomie Moderne*, tom. i. p. 557.

Rue (Lat. ruta, Gr. ῥυτή). The common name of *Ruta graveolens*, a native of the South of Europe, commonly cultivated in this country. It is a shrubby plant, with pinnately divided bluish-green leaves, and yellowish flowers, the whole plant possessing a powerfully fetid odour and acrid taste, dependent on the presence of a volatile oil. Rue is used medicinally as a stimulant and narcotic in flatulent colic, hysteria, &c. Locally applied, it acts as a powerful irritant. One species, indeed, *R. montana*, is said to be so powerful that it is dangerous to handle the plant, even when the hands are protected by gloves. Rue was employed medicinally by the ancients: for ages it was considered potent to ward off contagion, and it is still employed to keep off noxious insects. Rue enters into the composition of the French perfume, entitled *Vinegar of the four thieves*. [Thieves' Vinegar.] The Italians are stated to eat the leaves in salads. Shakspeare speaks of Rue as herb of grace.

Ruff. The name of the male of the *Machetes pugnax*, which is distinguished at the breeding season by a ruff or tuft of wide-spreading feathers, projecting behind the eyes and from the upper part of the neck. The female is called the *reeve*. [Machetes; Tringa.]

Rufin (Lat. rufus, *red*). A red substance formed by the action of heat on phloridzin.

Ruin Marble. [Cotham Marble.]

Rule (A.-Sax. regol, Ital. regola, Lat. regula). In Arithmetic, denotes a certain prescribed series of numerical operations, adapted to discover, from the given conditions to which an unknown number is subjected, what that number is. They are generally distinguished by particular names, according to the purposes for which they are given, or the particular nature of the business for which they are required; as the rules of interest, the rules of fellowship, &c.

Rule. In Law, an order of one of the three superior courts of common law. Rules are either general or particular; the former being such orders relating to matters of practice as are laid down and promulgated by the court for the general guidance of the suitors: the latter are such orders as are confined to the particular case in reference to which they have been granted.

The term is often used generally to denote a legal doctrine. [Courts, Superior; Pleading.]

Rule. In a monastic sense, a system of laws or regulations by which monasteries and other religious houses are governed, and which the monks, nuns, and novices vow, on their entrance, to observe. [Monachism; Orders, Monastic.]

Rule, Carpenter's. A folding ruler, generally used by carpenters and other artificers, having a variety of scales adapted to facilitate by inspection the calculations of most frequent occurrence. Sometimes it has a sliding piece in one of its legs, by which its use is greatly extended. [Sliding Rule.]

Rule, Gauging. A rule adapted to discover the contents of casks and other vessels. It is used by the officers of excise in surveying, in the process of manufacture, articles that are liable to duties. [Gauging.]

Rule of Signs. Besides the rule known in the theory of equations as Descartes' Rule of Signs, there is another of frequent use in the theories of permutants, commutants, determinants, &c. which may be thus ennunciated: *Any primitive arrangement of symbols being fixed upon, the sign to be prefixed to any other arrangement of the same symbols is positive or negative according as the latter arrangement is obtainable from the first by an even or odd number of successive interchanges of two symbols.*

This rule involves no ambiguity; for although there are many different ways of deriving a given arrangement from the primitive one by successive interchanges of two symbols, it can readily be shown that the number of such interchanges is constantly even or else constantly odd. Thus 1, 2, 3, 4, 5, being the primitive arrangement, 1, 4, 5, 2, 3, will be a positive and 2, 5, 1, 4, 3, a negative one in whatever manner the latter may be derived from the first by successive interchanges of two symbols. The rule of signs as ennunciated by Cramer (*Analyse des Lignes Courbes*, 1750) is often more convenient in practice. *An arrangement is positive or negative according as it contains an even or odd number of displacements*; it being understood that a displacement consists in the inversion of the order of sequence of any two symbols, in the primitive arrangement. Thus, since in the arrangement 1, 4, 5, 2, 3, the numbers 4 and 5 each *precede* two lower numbers; instead of being preceded by them as in the primitive arrangement, there are *four* displacements, and the arrangement is positive; again, in 2, 5, 1, 4, 3, the circumstance of a greater number preceding a less occurs *five* times, so that the arrangement is negative.

The equivalence of the above two rules can be easily proved. [Permutations.] It is established in Balzer's *Theorie und Anwendung der Determinanten*, Leipzig 1857, and was first demonstrated, by Laplace (*Histoire de l'Acad. de Paris* 1764).

Rule of Three. In Arithmetic, the rule by which when three numbers are given a fourth is to be found, so that the four shall be in direct or inverse proportion, as the case may require. [Golden Rule.]

Rules. In Building operations, this term is applied to the screeds, or portions of plastering executed on the face of a wall for the purpose

of floating the works in order to retain their perpendicularity, or their evenness of surface.

RULES. In the Fine Arts, those laws and maxims, founded on the general and fundamental truths of nature, by which artists are guided in their compositions.

Rules, Brass. In Printing, pieces of brass of different thicknesses made letter high, to print with type. They are made in lengths of fourteen inches, but of late years lengths half as long again have been made. One of the edges is bevelled so as to print a fine line; and when a thicker line is required, the bottom edge is placed uppermost, which is the full thickness of the brass; by this means lines of different thicknesses are obtained, and also double lines, a thick one and a fine one, when required. They are used for column lines in table work; to separate matter that requires to be distinct; and to be placed round pages. In cases where diagrams are required, and there is no engraver within reach, they may be formed by a clever workman with brass rule.

Ruled Quadric. In Modern Geometry, a ruled surface of the second order. Besides the cone and the three cylinders, there are two ruled quadrics, the hyperboloid of one sheet and the hyperbolic paraboloid, both of which are *skew* quadrics. [QUADRIC; RULED SURFACE.]

Ruled Surface. In Geometry, a surface generated by the motion of a straight line. At every point of such surface, therefore, a straight-edge or *ruler* may be applied so as to lie wholly on the surface. The straight line is called the *generator*; if every pair of successive generators intersect one another, or are in the same plane, the ruled surface could obviously, without crumpling or tearing, be unfolded into a plane, on which account it is called a *developable surface*: in other cases where two consecutive generators do not intersect, it is said to be a *skew surface*.

The motion of the generator may be defined in many different ways, and the treatment of the problem of finding the ruled surface will vary accordingly. Frequently the motion of the generator is regulated or directed by three curves or *directrices*, each of which the generator must always cut. That this is possible, is evident on considering that the cones whose common vertex is a point on one direction, and whose generators rest on the other two respectively, will necessarily intersect each other in a finite number of lines, cutting all three directrices. In fact, if n_1, n_2, n_3 denote the orders of the three directrices, there will be $n_2 n_3$ generators through every point of the first, $n_3 n_1$ through every point of the second, and $n_1 n_2$ through every point of the third; so that the three directrices will be multiple curves on the ruled surface; the orders of multiplicity being, respectively, $n_2 n_3$, $n_3 n_1$, $n_1 n_2$. To determine the order x of the ruled surface itself, or the number of its generators which meet any arbitrary line, we have, in the first place, to remember that a curve of the n^{th} order in general cuts a surface of the m^{th} in mn points. [CURVE.] Now, if x_1 be the order of the ruled surface whose directrices are the curves (n_2), (n_3), and any right line A_1, the curve (n_1) will meet $n_1 x_1$ of its generators. But these are clearly generators of the required surface meeting an arbitrary line A_1; hence $x = n_1 x_1$. In a similar manner, if x_2 be the order of the ruled surface whose directrices are (n_3), A_1, and another arbitrary line A_2, then $x_1 = m_2 x_2$; but, lastly, the ruled surface whose directrices are three right lines A_1, A_2, A_3, is of the second order, hence $x_2 = 2m_3$, and thus $x = 2n_1 n_2 n_3$.

To find the equation of the surface, we might proceed thus:

$$x = a z + a, \; y = \beta z + b,$$

being the equations of any generator, and $U = 0$, $V = 0$ those of one of the directrices, the elimination of $x\ y\ z$ from the four equations will give a relation between a, a, β, b; two similar relations will be obtained from the other directrices, so that, counting the two equations of the generator, we shall have, on the whole, five equations, from which if a, a, β, b be eliminated, the equation of the ruled surface will be obtained. For other properties of ruled surfaces, see SKEW SURFACE and DEVELOPABLE. Some of the most instructive works on the subject are those of Monge, *Application de l'Analyse à la Géométrie*; Dupin, *Developpements de Géométrie*; Chasles, *Quetelet's Correspondance*, t. xi.; Cayley, *Cambridge and Dublin Math. Jour.* vol. vii. &c.; and Salmon, *An. Geom. of Three Dimensions*. An important curve on every ruled surface is its *line of striction*, or the locus of the point on each generator which is nearest to the consecutive generator. [SKEW SURFACE.] It may be added, too, that the polar reciprocal of a ruled surface is another ruled surface of the same order.

Rum (a word of unknown origin). A spirituous liquor distilled from the fermented juice of the sugar cane, or from molasses. Its flavour is due to the presence of a peculiar volatile oil: its average proportion of alcohol fluctuates between 50 and 56 per cent. The rum consumed in the United Kingdom is manufactured chiefly in the islands belonging to Great Britain. It was formerly supposed that the consumption of rum would be aided by the imposition of differential duties on the produce of other countries; and hence the old duty on West India rum was 9*s*., on that imported from other regions 15*s*. But the duties on all spirits, whatever be their origin, are now equalised, and the effect has been that the consumption has been determined by dearness and cheapness. It is the practice of government to put the duty on spirits at that point which is just below the temptation to smuggling and illicit distillation. There is, it is reported, some difficulty in discovering this limit. In all probability it varies with the material

prosperity of the consumers. In the year ending March 1865, the customs duty on rum amounted to 1,908,057*l.*; on brandy, to 1,246,158*l.*; while the excise on spirits was upwards of ten millions. The cheapest article is the most productive. West India produce has still some slight protection in the fact that rum is still used almost exclusively in the navy. This practice—originally part of our colonial policy—is, it is said, judicious, for, of all spirits, rum, when kept long enough and properly mixed, is reported to be the most wholesome.

Rumen (Lat.). The name of the paunch or first cavity of the complex stomach of the Ruminant quadrupeds.

Rumex (Lat. sorrel). A large genus of weedy herbaceous plants, represented by the common Dock, one of the greatest pests to the agriculturist. The most useful species are the Sorrels, *R. acetosa* and *R. scutatus*. The former of these, the Common Sorrel, was cultivated in gardens for its leaves, which were used as spinach or in salads, in the time of Henry VIII.; but since the introduction of the French Sorrel, it has gradually lost its position as a salad and potherb. *R. scutatus*, or French Sorrel, is considered preferable to the common, on account of its leaves being larger and more succulent, with rather less acidity. The Sorrels are all of great importance in French cookery, and are both agreeable to eat and very wholesome, although but little valued in this country, except at some of the most fashionable tables. On the Continent sorrel is extensively cultivated, and in the vegetable markets of Paris it is nearly as abundant during the season as peas are in those of London. It abounds in oxalic acid, and is regarded as a powerful antiscorbutic.

Ruminants (Lat. rumino, *I chew the cud*). The name given by Cuvier to the *Pecora* of Linnæus, an order of Ungulate Mammals, including those which have a complicated stomach of four cavities so disposed as to allow of rumination, and a cloven hoof.

Ruminated (Lat. rumino, *I chew*). In Botany, a term applied to those seeds in which the albumen is penetrated by irregular channels filled with softer cellular matter, as in the Nutmeg.

Rumination (Lat. ruminatio). The act by which food once chewed and swallowed is a second time subjected to mastication. Digestion is always preceded by this action in the order of Mammals, hence called *Ruminants*; but very rarely, and as an exceptional case, in any other animal. The stomach of the Ruminants is specially organised for rumination, consisting of four distinct cavities, all of which communicate with a muscular canal at the termination of the œsophagus. Hard, solid, or coarsely masticated food, passes from the beginning of the muscular canal into the first cavity of the stomach, called the *rumen* or paunch. Water is received into the second cavity, called the *reticulum*, and almost exclusively occupies the honeycomb cells of that cavity; it is gradually mixed with the coarsely divided food which is undergoing mastication in the rumen. When this is sufficiently advanced, a portion of the mass is received into the muscular canal at the termination of the œsophagus; it is there moulded into a ball, and propelled by a rapid and inverted action of the muscles of the gullet into the mouth, where it is more perfectly masticated, mixed with fluid, and again swallowed. It now passes directly into the third stomach, called the *psalterium*, from the broad leaf-like plates of membrane with which it is occupied. Here the superfluous fluid, which otherwise might have too much diluted the gastric juice, is absorbed, and the subdivided cud passes gradually into the fourth or true digesting stomach, called the *abomasus*. In the camel tribe, water-cells are developed at the sides of the rumen, in addition to those of the reticulum, and the psalterium is not separated by any contraction from the abomasus.

Rump Parliament. In English History, after the dissolution of Richard Cromwell's parliament, and his own demission of the protectorate, a council of officers, at whose head were Desborough, Lambert, and others, having seized the supreme authority, found it advisable to call together the remnant of the Long Parliament, which had been forcibly dissolved by Oliver. It was assembled in May 1659; and consisted of little more than seventy members, those who had been excluded not being allowed to resume their seats. This body soon became odious to the Presbyterian and Royalist parts of the nation, and by its own assumption of power displeased the officers who had called it again into being. It acted, however, with some vigour and determination, and defeated a variety of royalist conspiracies; but when it ventured so far as to cashier Lambert and others of the leading officers, the troops again surrounded Westminster Hall, and expelled it on the 13th October in the same year. As, however, Fleetwood, who had the command of the army, was unable to keep together the distracted government, the officers once more invited the parliament to sit again, and on the 26th of December it once more assumed absolute authority; but General Monk took part against it. On his invitation, a good many of the excluded members went to the house (Feb. 21), and thus placed the Independents, who had hitherto ruled it, in a minority; and having passed some measures reversing its former acts, the parliament dissolved itself. It received its nickname from being, as it were, the remnant and fag-end of the old Long Parliament, and was treated by the nation with general contumely and derision. But it cannot be denied that, utterly unable as it was to command the divided nation, it showed in its conduct a boldness and vigour which with a little more popularity would probably have insured success. Vane and Hazlerig were its leading members.

Runcinate (Lat. runcina, *a large saw*). In Botany, having lobes hooked back, or curved in a direction from the apex to the base; as the lobes of the leaf of the dandelion.

Runes (Ger. runen). Properly the signs or letters of the ancient alphabet peculiar to the northern nations (Germans and Scandinavians). There are three theories on this subject, one maintained by Schlözer, who holds the sixteen Runic letters to be a corruption of the Roman alphabet, post-Christian in date; the second, that of Schlegel, who deduces this alphabet from the Phœnicians. (*Lectures on Ancient and Modern Literature.*) The third theory supposes the Runic to be the original character of the Indo-Teutonic tribes, brought from the East and preserved among the different races of that stock. The earliest writer who mentions the Runic characters is Venantius Fortunatus, in the sixth century. The Runic inscriptions found in Germany (especially Northern Saxony) are thought by some to exhibit tokens of an origin somewhat different from Scandinavian. (Grimm, *On the German Runes*, 1821.) The antiquity of both has been much disputed. Of those found in Gothland, it is said that the oldest are not earlier than A.D. 1200, the latest 1449. 1,300 stones with Runic inscriptions have, it is said, been discovered in Sweden; many in Denmark; none in Lapland or Finland. Runic staves are massive sticks, generally of willow, inscribed with Runic characters, probably of magical import. (Gibbon, *Roman Empire*, ch. ix. vol. i. 231, Milman's edition.)

Runner. In Botany, any slender prostrate stem, which throws out roots at the extremity, as in the Strawberry.

Runner Tackle. A luff tackle applied to the running end of a rope passed through a movable pulley.

Rupee. A coin circulating in the Indian peninsula. There are two kinds of rupee, the sicca rupee, estimated at 1*s.* 11·77*d.* sterling, and that known familiarly as *the Company's* rupee, worth fifteen-sixteenths of the former, and therefore valued at 1*s.* 10·29*d.* sterling, reckoning silver at 5*s.* the oz. A *lac* is 100,000, a *crore* 10 millions of rupees. [Money.]

Rupia (Gr. ῥύπος, *filth*). An eruption of flattish vesicles, succeeded by an ill-conditioned discharge, which concretes into scabs easily rubbed off and regenerated; they sometimes occur as a consequence of poor diet and weak habit of body; but there is a rupia which constitutes one of the most painful sequelæ of syphilis. Light nutritious food, tonics, and alteratives are the remedies.

Rupture. [Hernia.]

Rural Dean. An officer of the church, originally a kind of deputy of the bishop, for the purpose of inspecting the conduct of the parochial clergy within the limits of his deanry, enquiring into and reporting dilapidations, &c. This office had become nearly obsolete, but it has been resuscitated in modern times, and is now in general use. Rural deans receive no payment, and exercise no jurisdiction; their office is one of inspection only.

Rural Economy. The general management of territorial property, either by the proprietor or his agent. On a small scale, the agent is termed a *bailiff* or *farm servant*; and on a large scale, a *land steward* or *factor*. The duties of the latter are to collect the rents, to maintain the general equipment of the estate, and to see that the different clauses in the leases by which the tenants hold their lands are fulfilled; of the former, to cultivate the land in such a manner as to produce the greatest profit, or to fulfil the intentions of the proprietor as to the kind of produce which he considers it desirable to obtain. [Agriculture.]

Rush, Polishing. The Polishing Rush or Dutch Rush are commercial names of *Equisetum hyemale*, which in consequence of the large quantity of silex contained in its tissues is imported, principally from Holland, as a material for polishing wood, ivory, and brass. The greater number of the particles, according to Brewster, form simple straight lines, but the rest are grouped into oval forms connected together like the pearls of a necklace by a chain of particles, these rows of oval combinations being arranged in pairs. The straw and chaff of wheat, &c., which when burnt is also good for polishing, presents analogous phenomena, but the particles are arranged in a different manner.

Russian Mats. A kind of matting manufactured in Russia from the inner bark of the Linden, *Tilia europæa*. Russian mats are used in packing, and also as a protecting material in gardens; while the *bast* of which they are formed is used for tying up plants.

Rust (Dutch roest, Ger. rost, perhaps akin to *crust*). In its ordinary acceptation, the reddish peroxide which is found on the surface of iron when exposed to moisture.

Rust. In Horticulture. [Mildew.]

Rust. The common name of *Trichobasis Rubigo vera*, a parasitic fungus, which, with one or two closely allied species confounded with it by the farmer, preys upon the leaves, glumes, stalks, &c., of Cereals. Rust does not appear to be injurious to corn, so long as it is confined to the flaggy leaves, as it seldom grows except when they are over-luxuriant, but it is a formidable adversary when it attacks the chaff or seed; and the more so because it is impossible to suggest any remedy. Every protospore is shed long before the grain is reaped; therefore steeping is useless, and the application of any dressing to the soil is equally ineffectual.

Rustem. In Persian Mythology, a hero who slays Isfendiyar, as Sifrit is slain in Teutonic legends, by casting a thorn into the one spot where, like Achilles and other solar heroes, he is vulnerable. Rustem in his turn can be killed only by his brother, as Baldr can be slain only by the mistletoe, and as Hector can be slain only by Achilles, and the latter only by Paris, who again can be fatally wounded only by the poisoned arrows of Heracles. [Mythology, Comparative.]

Rustic (Lat. rusticus, from rus, *the country*). In Architecture, a name applied to masonry employed in basements with large joints to mark the different courses of stones. It is applied to work left with an irregular surface, or jagged out in an irregular manner.

Rutabaga. The Swedish Turnip, *Brassica campestris rutabaga.*

Rutaceæ (Ruta, one of the genera). A natural order of hypogynous Exogens, of the Rutal alliance, composed principally of trees and shrubs inhabiting the warmer parts of the world, seldom of herbaceous plants. They are known by their hermaphrodite flowers, few-seeded, prickly apocarpous fruit, and sessile pendulous ovules. The species are sometimes very ornamental, especially those belonging to the genera *Correa, Boronia,* and *Diosma.* Some, as the common Rue, the Buku plant, &c., are remarkable for having a powerful, peculiar, unpleasant odour, and antispasmodic quality; and a few have a febrifugal bark. The *Dictamnus albus,* or Fraxinella, is extremely fragrant, and gives off an inflammable vapour.

Ruthenium. A metal closely resembling iridium, with which it is associated in the residue from crude platinum insoluble in aqua regia. [PLATINUM.]

Rutherfordite. A titanate of lime found in iron-black crystals and grains, at the Gold-washings of Rutherford county, North Carolina.

Rutile (Lat. rutilus, *shining red*). Native titanic acid; composed, when pure, of 60·98 per cent. of Titanium and 39·02 oxygen. It is found crystallised and massive in Argyleshire, Perthshire, Fifeshire, and the Shetlands; also in France, the Alps, Brazil, &c.

Rutilite (Lat. rutilus, *red*). Native titanate and silicate of lime. [SPHENE.]

Rutinic Acid. An acid contained in the leaves of rue.

Rutton-root. The name of an Indian dye root, that of *Maharanga Emodi.*

Ryacolite (Gr. ῥύαξ, *a* [*lava*] *stream,* and λίθος, *stone*). A silicate of alumina, soda, potash and lime, occurring in thick tabular, or short prismatic crystals, like Glassy Felspar, of which it is, perhaps, only a variety. It is white or of a grey colour, with a vitreous lustre, and is transparent or translucent. It is chiefly found at Vesuvius in ejected blocks with Nepheline, Augite, and Mica; and at Lake Laach.

Rye (Ger. roggen, Dutch rog, rogge). One of the Cereal grasses, which, according to some, is a native of Crete, but according to others is found wild in the Crimea. It has been cultivated from time immemorial, and is considered as coming nearer in its properties to wheat than any other grain. It is more common than wheat in many parts of the Continent, being a more certain crop, and requiring less culture and manure. It is the bread-corn of Germany and Russia. In Britain it is now very little grown, being no longer a bread-corn, and therefore of less value to the farmer than barley, oats, or peas. Its chief use in English agriculture arises from its early spring growth. The St. John's Day rye, sown soon after midsummer, stands the winter, and, cut in April, furnishes the earliest green food available for the stable, byre, or sheepfold in spring.

Ryot (Arab. *a peasant* or *serf*). The cultivators of the soil in Hindustan, who pay the land tax are designated by this name; the proportion, one-sixth in peace, one-fourth in war, at which the rate should be levied from the produce having been determined in the ancient sacred works of the Hindus. It was seldom, however, that the native rulers were content with the quantity fixed by these authorities, but generally taxed their subjects to the fullest possible extent.

When the English obtained possession of Hindustan, they adopted the system of farming the revenues. Such an expedient was no improvement on the administration of the native princes. The farmers were an army of tyrants. Holding their office for a short time only, they were eager to procure every possible advantage to themselves; and being checked by no efficient control, they cruelly abused the powers necessarily accorded to their office. The farmers actually depopulated the country.

The inconveniences which followed on this system induced Lord Cornwallis to attempt a change. He, no doubt, meant honestly and fairly by the natives; but being wholly ignorant of the peculiar land tenures of India, and the rights involved in them, he attempted to set up a modified feudal system. The farmers were turned into landlords under the title of *zemindars,* were rendered liable to a fixed and permanent tax, and received rents from the ryots. Remedies in English courts of law were supplied to the ryots in case they were oppressed by their new masters.

These zemindars were a local aristocracy in name only. They were often despised by the rajpoots as persons of inferior caste; in all cases they had been elevated to the rank which they occupied by the force of purely fortuitous causes. The natives availed themselves of the assistance of the English law courts. In one district it is said that no less than thirty thousand suits were lodged against the zemindars. But these officials, though liable to summary procedure if they defaulted for a single month in the payment of their taxes, could proceed against the ryots only by very slow processes. Added to this, they were often, as many other upstarts are, profligate, licentious, and extravagant. In a very short time the zemindary system disappeared, and in its place a settlement was made for thirty years at a variable rent. In effect it is found that this arrangement has not been satisfactory, and considerable disaffection has from time to time been expressed by the natives of the Bengal presidency and their advocates.

In Madras, into which the Mohammedan conquerors had not penetrated, the ancient village system prevailed, with its headman, who governed the land, distributed its products, and was responsible for the payment of taxes

to government. Here the occupation of the English led to investigations into the system by which the land tax was levied, and a new plan, the exact reverse of the zemindary system, was instituted. Colonel Read and Sir T. Munro set up what has been called the ryotwary system; the chief feature of which was, that the government was henceforth to transact its business with the individual ryot, no other person intervening. This scheme annihilated the ancient village system, which had prevailed for so many ages in India, and induced as a consequence enormous social difficulties. Besides, as under this new method it was necessary to map out and measure an infinity of allotments, the physical difficulties were almost insuperable; not to mention the prodigious expense of such an admeasurement, and the inevitable discontent that would arise. To complete the folly, it was resolved to make the rent permanent, as if a peasant could pay a fixed rent with equal ease in all seasons and under all circumstances.

After having destroyed the village system, and having found it necessary to abandon the zemindary and ryotwary, the government attempted to revive the village system in a modified form, under the name of Mouzawar. The plan failed, for the new headmen of the villages, not having been appointed in pursuance of the traditions of the ancient Indian institutions, were avaricious and oppressive, and odious to the ryots.

It became necessary then to establish the ryotwary system on a new basis; and having gained experience from past errors, the Indian land tax was put on as fair a basis as was possible under the circumstances.

The principal members of the Hindu village, according to Mr. Richard Jones, were the headman, the registrar, the police magistrate, the land measurer, the boundary man, the Brahman or priest, the schoolmaster, the astrologer, the smith or carpenter, the potter, the washer-man, the barber, the cow-keeper, the doctor, the dancing girl, the musician, and the poet.

Rytina (Gr. ῥυτίς, *a wrinkle*). The name of a genus of herbivorous Sirenia, of which a species formerly inhabiting the coasts of Kamschatka (*Rytina Stelleri*), with a wrinkled and furrowed integument, is the type. Descriptions of this animal were given by Steller in the *Transactions of the Academy of St. Petersburg*, a few years after its discovery in the eighteenth century. The whalers who traded to Behring's Straits and the northern shores of Siberia killed large numbers of this animal for the sake of the blubber and oil; the result being the complete extinction of the species, of which no individuals exist at the present time in a living state.

S

S. A sibilant articulation, found in all the languages of which we have any knowledge. S may be regarded as a species of semivowel, from its forming a kind of imperfect sound without the aid of any of the vowels; and from its peculiar quality of being able to be sounded before all the consonants, it has been termed by grammarians *suæ potestatis litera*, It is susceptible of many interchanges, both in the ancient and modern languages. As an abbreviation, S is used for *socius*, *societas*, *south*, *solo*, &c. [DIGAMMA.]

Sabadilline. One of the poisonous alkaloids of white hellebore.

Sabaism (from the Heb. zaba, *lord*; whence sabaoth, &c., or *army*, *the host of heaven*). The religion which has for its objects of worship the sun, moon, and other heavenly bodies. This belief prevailed in very remote ages in the Asiatic countries between the Euphrates and the Mediterranean; and Chaldæa, the native land of astronomy, was its most celebrated seat. Sabaism was one of the various forms of idolatry borrowed by the Jews from their heathen neighbours. It was also widely prevalent in Arabia; and according to some recent and singular revelations respecting that country, still subsists in parts, under the cover of an ill-assumed Mohammedanism. (Sale's *Preliminary Discourse to the Koran*; *Mém. de l'Acad. des Inscr.* vol. xxv. p. 100; Palgrave's *Central Arabia*.) The word *Sabaoth* occurs in the New Testament as a designation of the Almighty (the Lord of Sabaoth).

Sabal. A genus of Palms, including one of the most northern representatives of that order, *S. Palmetto*, reaching in Carolina as far north as lat. 34° 36′. They have large fan-shaped leaves, and in some species stems of twenty to thirty feet high. The soft interior of the short stem of *S. Adansoni* is eaten in the southern states of America, and its leaves, as well as those of *S. Palmetto*, are used for plaiting into hats, resembling what in this country are called *chip-hats*. In Mexico the leaves of *S. mexicana* are applied to a similar use.

Sabazius (Gr. Σαβάζιος). A Phrygian divinity, identified by the Greeks with DIONYSUS. Zeus, however, is also sometimes called Zeus Sabazius. Serpents, which were sacred to him, were borne in processions made in his honour.

Sabbatarians. In Ecclesiastical History, various sects have been so called; particularly a subdivision of the Anabaptists in the six-

teenth century, who observed the Jewish sabbath. The *Sabbatians* of the fourth century were followers of Sabbatius, a Novatian bishop. (Socrates, *Hist. Eccl.* v. 21.)

Sabbath. A Hebrew word signifying *rest*, applied by the Jews to the seventh day of their week (our Saturday), on which they were commanded to abstain from all manner of work. The universal practice of the Christian church from a very early period has set apart the first day of the week (Sunday) in especial memory of the Resurrection. The obligation upon which the observance of Sunday rests has been placed upon different grounds. (Hessey's *Bampton Lectures* for 1860; *Edinburgh Review*, Oct. 1861; Robert Cox, *Literature of the Sabbath Question.*)

Sabbatical Year. Every seventh year among the Jews was so called, in accordance with the precepts given in Exod. xxiii. 10, Lev. xxv. 3, 20.

Sabellians. The followers of Sabellius, in the third century, whose system was an attempt to explain the doctrine of the Trinity by representing the Father as the sole Person, and the Son and Spirit as attributes, or emanations from Him. Thus they compared the Divinity to the sun; of which the Father would be analogous to the substance, the Son to the light, and the Holy Ghost to the heat. This scheme has been known in later times as that of the Modal Trinity; and some divines of the church of England appear to have adopted it, when attempting to explain accurately the doctrine to which it refers, while their opponents, making too formal a distinction of the Three Persons, have been subjected to the charge of Tritheism.

The followers of Praxeas, who maintained the Sabellian thesis, asserted that the Father had united to Himself the human nature of Christ, and were hence called Monarchians, while they were also styled *Patripassians*, as holding that the Father suffered in the death of Christ.

Sabiaceæ (Sabia, one of the genera). A small order of hypogynous Exogens, nearly allied to *Sapindaceæ* and *Anacardiaceæ* in the structure of the ovary, fruit, and seeds, but differing essentially in the stamens being equal in number and opposite to the petals, two of the stamens being usually much larger than the others and perfect, the two or three others much smaller and often without anthers. The species are all tropical trees, shrubs, or woody climbers, with alternate simple or pinnate leaves without stipules, and small flowers usually paniculate. They occur both in the New and the Old World.

Sabians. A Christian sect, also called Christians of Saint John; thought by some to be the remnant of the Jewish Hemerobaptists found in Persia and Arabia, principally at Basra. (*Mém. de l'Acad. des Inscr.* vol. xii.; and Mosheim, vol. iv.)

Sabicu Wood. A hard shipbuilding timber, obtained from Cuba, and produced by *Lysiloma Sabicu*. It is sometimes called Savicu or Savico Wood.

Sable (Ger. zobel, Fr. zibeline). A small quadruped, allied to the marten-cat, celebrated for the fine quality and rich colour of its fur, of which the hairs turn with equal ease in every direction. A single skin of the darker colour, though not above four inches broad, has been valued as high as 15*l*. The sable (*Mustela zibellina*, Linn.) is principally a native of the northern regions of Asia: it is hunted and killed for the Russian market, either by a single ball, a blunt arrow, or traps, by exiles or soldiers sent for that purpose into the deserts of Siberia. The skin is in the highest perfection from November to February. A nearly allied animal, called the *fisher*, inhabits North America, and is similarly sought after and destroyed for its fur.

Sable. In Heraldry, *black*: derived, probably, from the fur of the animal sable. One of the colours, or tinctures, employed in blazonry. It is equivalent to diamond among precious stones, Saturn among planets. In engraving, it is represented by vertical and horizontal lines crossing each other.

Sabôt (Fr.). In Artillery, a wooden top or bottom fixed to a shell, in order to keep the shell from rolling while entering the bore, thus insuring that the fuse is not next the charge, in which case the shell would burst in the gun. It also saves the bore of a bronze gun from injury by the rebounding of the shot.

The name *sabôt* is also given to the heavy wooden shoe worn by the poorer classes in France.

Sabre (Fr.). A curved sword used by cavalry.

Saccharic Acid (Lat. saccharum, *sugar*). An uncrystallisable acid product, formed along with oxalic acid during the action of nitric acid on sugar.

Saccharimetry. The operation of estimating the amount of sugar in any substance that may contain it. The specific gravity is sufficient for this purpose in the case of pure syrups. In some other cases advantage is taken of the extent to which a given volume of a saccharine solution twists a ray of polarised light. The latter operations may also be applied in the case of mixtures of cane and grape sugar. Both twist the ray to the right, but the former alone has this power inverted on ebullition with hydrochloric acid; a fact which, when applied, obviously affords experimental data for the calculation of the quantities of each present. Another saccharimetric method consists in converting the cane sugar into grape sugar by boiling with dilute sulphuric acid for two or three hours, and then heating with solution of potash or soda, and comparing the depth of colour of the resulting dark brown liquid with similar liquors prepared from known weights of sugar. Grape sugar will also reduce an alkaline solution of tartrate of copper with precipitation of orange yellow sub-oxide of copper. This reaction is perfectly definite, and may be applied in the estimation of grape or cane sugar, or both.

Saccharite (from its saccharine appearance, like that of loaf-sugar). A hydrated variety of Andesine, occurring in finely granular masses of a white or greenish colour, forming veins in Serpentine at the chrysoprase mines near Frankenstein in Silesia.

Saccharoid (Lat. saccharum, and Gr. εἶδος, *form*). A texture resembling that of loaf sugar; as saccharoid carbonate of lime, &c.

Saccharometer (Lat. saccharum, and Gr. μέτρον, *a measure*). An instrument for determining the specific gravity of brewers' and distillers' worts.

This name is also given to an instrument for determining by polarised light the quantity of real sugar in saccharine solutions.

Saccharum (Sansc. sarkara). A genus of grasses, the most important species of which is *S. officinarum*, the Sugar-cane, which has been cultivated from time immemorial, and was known to many savage tribes of the Eastern hemisphere, who grew it for the sake of sucking the stem or sweetening their food with the raw juice. The native country of the Cane is doubtless the Eastern hemisphere, but the exact locality whence it spread is unknown. India lays claim to it, and our name Sugar is a corruption of a Sanscrit word. New Caledonia, in the South Pacific, has also a peculiar claim to be regarded its native country, for there the Sugar-cane grows with rapidity and attains an extraordinary size, and the barbarous natives of that large island possess an endless number of varieties. The manufacture of sugar is supposed to have been derived from China. The consumption of sugar is largest in Australia, where the European population uses about 100 lbs. per head; whilst in England 36 lbs. and in Russia only 2 lbs. per head are consumed. Sugar is made into molasses and rum, and is also used medicinally. [SUGAR.]

Sacer Morbus (Lat. *sacred disease*). One of the names applied by the older writers to epilepsy, though other disorders were also occasionally similarly designated.

Sack (Fr. vin sec, *dry wine*). A Spanish wine of the dry kind. The important part which it plays in Shakspeare is well known. Falstaff calls it *sherris sack*, which means sherry sack; so called, says Blount, in his *Glossographia*, from Xeres, a sea-town of Corduba, where that kind of sack is made. At a later period, sack seems to have been used as a general term for all kinds of sweet wines; and it has been conjectured that, instead of being a corruption of the French *sec*, as above noticed, it derives its name more probably from a common practice of the Spaniards, of putting their sweet wines into *sacks* made of goat skins, and thus transporting them from one place to another.

Sack-tree. [LEPURANDRA.]

Sackbut (Fr. saquebute, Span. sacabuche). A wind instrument of the trumpet species, but different from the common trumpet in form and size. It is of low or bass pitch, and is drawn out or shortened by the means of sliders, according to the acuteness or gravity of the tone to be produced. It is, in fact, the trombone of the Italians.

Sacrament (Lat. sacramentum, *an oath*). The military oath taken by every Roman soldier, by which he swore to obey his commander and not desert his standard.

SACRAMENT. In Theology, a word employed very early by writers in theology to signify certain distinctive ceremonies of the Christian faith, and especially the rite of Baptism, and the Eucharist or Lord's Supper. The former of these two sacraments is frequently called the second birth, the other is said to be the communion of the body and blood of Christ, while both are represented as having in themselves a peculiar efficacy, conferring grace upon the recipient, and imparting to him the benefits of the Christian covenant. The Roman church is accused of holding the opinion that this grace is conferred ex opere operato, by the mere act, the recipient remaining passive, and that they fail of operation only where he is under the influence of positive sin. According to Article XXV. of the Established Church of England, 'Sacraments ordained of Christ be not only *signs* or *tokens of Christian* men's profession; but rather they be certain sure witnesses and effectual signs of grace, and God's will towards us, by the which He doth work invisibly in us, and doth not only quicken, but also strengthen and confirm our faith in Him.'

The same article asserts that 'there are two Sacraments ordained of Christ our Lord in the Gospel, that is to say, Baptism and the Supper of the Lord,' and refuses the title of *Sacraments of the Gospel* to the five ordinances of Confirmation, Penance, Orders, Matrimony, and Extreme Unction, which, with those of Baptism and the Eucharist, make up the seven sacraments of the church of Rome.

Sacred War. The most remarkable war known by this name in classical history is that which commenced with the seizure of Delphi by the Phocians, B.C. 357, and was ended by the conquest of the Phocians by Philip of Macedon, B.C. 346, according to the chronology of Clinton. (*Fasti Hellenici.*)

Sacrifice (Lat. sacrificium). Generally, an offering made to the Deity, whether in token of gratitude, or as a means for obtaining His favour, or averting His wrath, or arresting His vengeance. The sacrifices of all heathen nations fall into two classes, the bloody and the unbloody.

It was the opinion of later Greek writers, such as Plato and Pausanias, that bloody sacrifices were of comparatively late introduction, and that the practice of offering human victims had been preceded by a system which prescribed the presentation of fruits, cakes, and libations. The earlier Greek literature fails to bear out this assertion; and a comparison of their traditions with those of other nations tends to show that the system of human sacrifice was at one time universal, and that the practice had some connection with cannibalism. Achilleus

makes a vow that he will solemnly offer up twelve Trojan youths (*Il.* xviii.) in expiation of the slaughter of Patrocles, and Zeus tells Hera (*Il.* iv. 35) that his wrath would be satiated if she would eat Priam and his children raw. The human sacrifices to Zeus Lycæus in Arcadia seem to have been offered down to the time of the Roman emperors. At Athens two victims were sacrificed, one on behalf of the men, the other on the behalf of the women, at the festival called Thargelia. According to Strabo, a man was thrown every year into the sea from a rock in Leucas in honour of Apollo. The offering of human figures made of rushes in the Lemuralia attests the practice of genuine human sacrifices among the earlier Latins, even if other evidence were wanting in the traditions or the history of later times. The idea that the value and efficacy of the offering was to be measured by the preciousness of the victim was soon developed, and, like Balak in the words of Micah (vi. 7), the parent imagined that he might atone for the sin of his soul by offering up the fruit of his body. The working of this idea is seen in the narrative of the offering of Isaac by Abraham (Stanley, *Lectures on the Jewish Church*), and in the frightful sacrifices of the valley of Hinnom. The inveterate addiction of the Jews to the custom of making their first-born pass through the fire, i. e. of burning them alive in honour of Moloch, is abundantly proved by the constant protests and remonstrances of their prophets. Among the Phœnician tribes the custom prevailed if possible in more horrible excess. During the invasion of Agathocles, the statue of Moloch at Carthage was fed certainly with 200, probably with 500, living children. (Grote, *History of Greece*, part ii. ch. xcvii.)

But in times of which we have historical knowledge, the bloody sacrifices of the Greeks and Romans were generally confined to the slaughter of brute animals. In the earlier times these seem to have been burnt whole [HOLOCAUST]; but in the Homeric ages the legs enclosed in fat, with certain parts of the entrails, were set apart for the gods, while the rest of the carcase furnished a banquet for the worshippers. This change is indicated in the legends of Epimetheus and PROMETHEUS. The gods were supposed to delight especially in the smoke of the sacrifice; hence the potency of the offering was proportioned to the number of the victims, and thus was developed the practice of offering a hundred oxen [HECATOMB], or of a larger number. Whatever may have been their effect on the gods, these sacrifices were undoubtedly acceptable to men as furnishing the means for lavish feastings. The sacrifices of Solomon at the dedication of the temple are said to have furnished the Jews with magnificent banquets for many days. (2 Chron. vii.)

The most common sacrifice of animals among the Romans was the suovetaurilia [LUSTRATION], answering to the Greek τριττύα.

The unbloody sacrifices comprised (1) libations, which especially accompanied the sacrifices offered on the completion of treaties, hence termed σπονδαί; (2) incense; (3) fruit and cakes, the former of these being offered chiefly as first-fruits or tithes of harvest, the latter being peculiar to the worship of certain gods, as of Apollo. These cakes were frequently made in the form of animals, and were then offered as a substitute for the sacrifice of the real animals.

Sacrilege (Lat. sacrilegium). In Roman Law, this crime was defined to be the stealing of sacred things (*sacrarum rerum furtum*), i.e. from a temple. In English Law, the offence of sacrilege is constituted by breaking and entering any church, chapel, meeting-house, or other place of divine worship, and committing any felony therein, or by committing any felony in any such place and then breaking out of the same; and is punishable in the same manner as burglary (stat. 24 & 25 Vict. c. 96).

Sacristan (Low Lat. sacrista). The person to whose charge the vestments used in divine service are committed. The name is now corrupted to *sexton*. In most of the old cathedrals the sacrist was the treasurer's deputy and a vicar choral. (Hook, *Church Dictionary*, s.v.)

Sacristy (Lat. sacer, *sacred*). In Architecture, an apartment attached to a church, in which the consecrated vessels of the church, and the garments in which the clergy officiate, &c., are deposited.

Sacrum (Lat.). In Anatomy, the sacrum is that vertebra, or series of vertebræ, usually anchylosed, which gives attachment to the modified hæmal arch called *pelvic*.

SACRUM. In Anthropotomy, the posterior bone of the pelvis, articulated to the last lumbar vertebra, and firmly united by synchondrosis on each side to the hip bones; below, the os coccygis is attached to it. In young subjects it is composed of five vertebræ united by cartilages, but in more advanced age it becomes one bone.

Sacti. In Hindu Mythology, the female power of the universe, as distinguished from Siva. (Muir, *Sanskrit Texts*, part iv. ch. iii. § vi.) This power is represented in the mysteries of Kali or Durga, the spouse of Siva, by a woman, who receives this title, and is purified for the office in a manner which exhibits the closest resemblance to the rites of initiation in the Eleusinian mysteries. The word is the same as SUTTEE.

Sadder. A work in the modern Persian tongue, comprising a summary of various parts of the ZENDAVESTA, or sacred books of the ancient Persians. The authority and character of the Sadder are supposed to be very small: some attribute it to the Parsees, and give it an antiquity of several centuries; others consider it a more modern forgery. (*Mém. de l'Acad. des Inscr.* vol. xxxviii.)

Saddle (Ger. sattle, Lat. sedile, Fr. selle). In Sea language, a lump of wood acting as a seat or rest to the heel of a boom, and shaped accordingly. It is principally employed in steadying the studding-sail-booms, and the jib-boom.

Sadducees. A sect of religionists among the Jews. It is remarked that during the time of the great Hebrew prophets there is no account of the existence of any sects among them. The most ancient sect was that of the Sadducees, whose founder, Sadok, lived about 250 years B.C. He appears to have restricted the providence of God to the distribution of the temporal rewards and punishments which form the main feature of the old dispensation; and his later followers entirely rejected the doctrine of a resurrection. [SOUL.] They were assimilated also to the Epicureans in maintaining the perfect freedom of human actions; and like those pagan philosophers were few in number, and only of the highest and most literary classes. They were distinguished also from the Pharisees by the rejection of tradition, and by strict adherence to the written law alone. (Milman's *History of Christianity.*)

Safe-conduct (the name as well as usage said to have originated in Italy: *salva condotta*). A license, or passport, from the proper authority, insuring to those who hold it personal safety while passing and repassing from one place to another, over ground occupied by enemies, in time of war. The prerogative of granting it belongs to the sovereign, or the officer in command to whom the sovereign has delegated it. Unless the language be expressly extended, it protects only one person and his *reasonable* baggage. If it be limited as to time, the holder is nevertheless entitled to equitable protection if he has been prevented from returning by some cause over which he has no control. (Phillimore's *International Law*, part ix. chap. viii.)

Safety Lamp. A lamp invented by Sir H. Davy, so constructed as to burn without danger in the explosive atmosphere of coal mines infested with fire damp. Flame may be considered as vapour or aëriform matter in a state of intense ignition; the temperature, therefore, of flame is always very high. Whenever flames emit much light, they derive that property from the presence of finely divided matter diffused through them. Thus, the intense brilliancy of the flame of phosphorus appears to depend upon the particles of incombustible phosphoric acid diffused through it: and the bright light emitted by a gas flame depends upon finely divided charcoal, which is ignited by the gas and at the same time burnt. The correctness of this *theory of flame* is shown by the circumstance of its being extinguished by cooling; and this is best effected by causing it to pass through a piece of fine wire gauze, which, when held horizontally in the midst of the flame, extinguishes its upper part, provided the flame is not projected under pressure, in which case if the pressure be great the flame will pass through. That the wire gauze acts merely by its cooling power, is shown by the flame passing through it when it acquires a white heat, or when its meshes are not fine enough to exert a due cooling power. It is also found that very hot flames, such as that of hydrogen, will pass through tissues impervious to flames of a lower temperature, such as that of a common candle or a gas flame. [FLAME.] The application of these principles to the construction of the safety lamp is as follows: The flame of a small oil lamp C is surrounded by a cylinder of wire gauze A B (doubled at A, where likely to become hottest, and protected by the stout wire frame D), and burns within it, the air having free ingress and egress through the gauze. When it is immersed in an explosive atmosphere, such as that of a coal mine infested by fire damp, the inflammable gas enters from without and burns *in* the cage; but, in consequence of the cooling power of the wire gauze, no flame can pass *outwards* so as to ignite the surrounding atmosphere: the miner, therefore, is warned of his danger by the appearance of the lamp. As long as the external atmosphere is safe, the lamp burns as usual; but upon the approach of the fire damp the flame is more or less enlarged; and in the most explosive condition of the surrounding air the cylinder appears filled with a blue lambent flame, which flickers within it, the wick of the lamp appearing for the time extinguished. It is, however, rekindled as the air becomes more pure; or should the fire damp greatly predominate, it may be entirely extinguished. Before this happens, however, the miner is duly apprised of his danger, and has time to retreat. (Davy *On the Safety Lamp.*)

Attempts have been made to light mines by the electrical light, which not being maintained by combustion may be kept up in an air-tight glass globe. The introduction of effectual means of ventilation into mines has of late received more attention than formerly, by which means accumulation of inflammable gas is prevented; and more attention is also paid to the state of the barometer, the evolution of gas from the coal being found to be in a great degree proportionate to the amount of barometric pressure.

Safety Valve. [STEAM ENGINE.]

Safflower. The *Carthamus tinctorius*, or Bastard Saffron, the dried flowers of which are used as a dye stuff, and in the preparation of the pigment called *rouge*.

Saffron (Welsh safrwn, Ger. and Dutch saffran). The prepared stigmas of the purple-flowered *Crocus sativus*. The stigmas of this species of crocus are of a deep orange colour, and have a peculiar and very characteristic odour; they are used in medicine, chiefly as a rich yellow or orange colouring matter. Saffron is principally imported from the South of Europe, especially Spain; formerly it was largely cultivated in this country in the vicinity of Saffron Walden in Essex. Saffron is often adulterated to a considerable extent with the

petals of other plants, especially with those of the marigold.

Saga (a Teutonic and Scandinavian word, connected with the verb sagen, *to say*). The general name of those ancient compositions which comprise at once the history and mythology of the northern European races. Their language is different from the modern Danish, Swedish, and Norwegian, and is more powerful and expressive than either of these later dialects. Of the mythological sagas the most famous are the saga of Ragnar Lodbrog, the Hervarar saga, the Voluspa saga, and the Wilkina saga. The historical sagas are very numerous; the Jomsvikingia saga and the Kaflinga saga comprehend much of the early annals of Norway and Denmark; the Eyrbiggia saga is the chief historical document of ancient Iceland. Many of them are collected in the great work of Snorre Sturleson called *Heimskringla*. [EPIC; MYTHOLOGY; NIBELUNGEN LIED; SIGURDR.]

Sagapenum. A fetid gum-resin brought from Persia and Alexandria, probably the produce of a species of *Ferula*. It is occasionally used in medicine as a nervine and stimulating expectorant. Its odour somewhat resembles that of assafœtida, but it is much weaker.

Sage. [SALVIA.]

Sageretia (after M. Sageret, a French vegetable physiologist). A genus of *Rhamnaceæ*, of which one species is *S. theezans*, the Tia of the Chinese. It is a native of Penang and the Philippine Islands, as well as of Southern China; and the poorer classes of the Chinese are said to employ its tea-like leaves as a substitute for true tea.

Sagger. A clay used in making the pots in which earthenware is baked, and which are called *saggers* or *seggers*.

Sagging to Leeward. A Nautical term, denoting the movement by which a ship makes considerable lee-way. It is the antithesis to *holding a good wind*, i. e. bearing up well to windward.

Sagitta (Lat. *arrow* or *dart*). One of Ptolemy's forty-eight constellations in the northern hemisphere. [CONSTELLATION.]

SAGITTA. A term used by the older writers on Trigonometry to denote the *versed sine* of an arc; from its resemblance to an arrow standing on the chord of the double arc.

Sagittarius (Lat. *the Archer*). One of the twelve constellations of the Zodiac. It is represented on celestial globes and charts by the figure of a centaur in the act of shooting an arrow from his bow.

Sagittate (Lat. sagittatus, from sagitta, *an arrow*). In Zoology, a part of an animal is so called when it is triangular and hollowed out at the base with posterior angles.

Sago (Malay, sagu, *bread*). A granulated form of starch obtained from various species of Palms and Cycads. The Sago of commerce is prepared from the soft inner portion of the trunks of *Sagus lævis* and *S. Rumphii*, which are sociable palms, growing together in large masses, principally in swampy places. It is obtained by cutting the trunks into pieces about two feet long, the pieces being then split in half, and the soft substance scooped out and pounded in water till the starchy matter separates, when it is drained off with the water, allowed to settle, and afterwards purified by washing. It is then in the form of sago-meal, but before being sent to this country it is made into what is termed ***pearl-sago***. In this process, the rough meal is first repeatedly washed and strained, then spread out to dry, and afterwards broken into small pieces, which, when sufficiently hard, are pounded and sifted until they are of regular size. Small quantities are then placed in a large cloth or bag suspended from the ceiling, and shaken backwards and forwards for about ten minutes, when the particles become granulated or pearled. They are then thoroughly dried and packed for exportation.

Other kinds of Sago are obtained from the stems of *Phœnix farinifera, Corypha Gebanja*, and *Caryota urens*, as well as other Palms and Cycads. What is called Portland Sago is obtained from the corm of *Arum maculatum*, collected in the island of Portland.

Sagum (Lat.). The cloak worn by the inferior officers and the soldiers of the Roman legion, in contradistinction to the PALUDAMENTUM of the generals. It was the dress of war, as the toga was the dress of peace, and was put on by all citizens when there was war in Italy. It was worn open in front, and generally fastened across the shoulder by a strap. This name was also given to the dress of several barbarous nations. Thus Tacitus says of the Germans, *tegumen omnibus sagum*; and Varro and Diodorus Siculus represent it as the costume of the Gauls.

Sagus (Malay sagu, *bread*). The name of the Sago Palm. The word *Sagus* is derived from *Sago* or *Sagu*, which in the language of the Papuan race signifies bread, and is given by them to the two palms from which the well-known Sago of the shops is obtained. [SAGO.] The former of these, *S. lævis* (alias *Metroxylon læve*), from which the greatest part of the sago exported to Europe is derived, grows from twenty-five to fifty feet high, and has a rather thick trunk marked with the scars left by fallen leaves, and usually invested towards the summit with the withered remains of leafstalks; above these the large pinnate smooth-stalked rather erect leaves form a graceful crown, from out of the centre of which the alternately-branched pyramidal flower-spikes arise, their bases being enveloped by smooth sheaths. The latter, *S. Rumphii* (alias *Metroxylon Rumphii*), resembles *S. lævis* in general appearance, but is usually a much smaller tree, and has its leafstalks and the sheaths enveloping the lower part of the flower-spikes armed with sharp spines from half an inch to about an inch long. These trees produce their flower-spikes when about fifteen years old, and the fruit is nearly

three years in ripening, after which they die. In order to procure the greatest quantity of sago, the trees must be cut down immediately the flower-spike make its appearance.

Sahara. The name given to the great desert of the north of Africa, extending from the Nile to the Atlantic coast and from the Atlas mountains to within 10° of the equator. Throughout this vast tract, which is an undulating and for the most part barren district, there are intervals of cultivated land, called Oases. The rest is an ancient sea-bottom, hard, smooth, and level, sometimes covered with sand, and often encrusted with salt. A considerable native traffic is carried on in various directions through the Sahara, and it is thinly peopled throughout with African tribes. With great difficulty and danger, European travellers have at various times succeeded in penetrating to the great central African city of Timbuctu, entering Africa from the north, north-east, south, and west. There is no natural drainage, by river, of any part of the Sahara, and but little rain seems to fall; water is occasionally found in springs and pools, but not during the whole year. The estimated area of the Sahara is two and a half millions of square miles, and the same condition of the surface extends out into the Atlantic, far beyond the African coast. The eastern extremity of the great Sahara, abutting upon Egypt, is covered with a vast accumulation of loose sand drifting eastwards, owing to the prevalence of winds from the west.

Sahlite. In Mineralogy, a greenish-grey variety of Pyroxene or Augite, resembling Diopside, found in the silver mine of Sahla, and in many other parts of Sweden.

Sail (Ger. segel, Dutch zeil). A surface obtained by canvas, mat, or other material, by the action of the wind on which, when extended, the vessel is moved. A sail extended by a yard hung (*slung*) by the middle and balanced, is called a *square sail*: a sail set upon a gaff or a stay, is called a *fore-and-aft sail*; which terms refer to the position of the yard, gaff, or stay, when the sail is not set. The upper part of every sail is the *head*, the lower part the *foot*; the sides in general are called *leeches*; but the weather or side edge of any but a square sail is called the *luff*, and the other edge the *after leech*. The two upper corners are *earings*, but that of a jib is the *head*; the two lower corners are in general *clews*; the weather clew of a fore-and-aft sail, or of a course while set, is the *tack*. The edges of a sail are strengthened by a rope called the *bolt rope*. The ropes at the upper and lower edges are the head and foot ropes of the sail. The canvas or sail-cloth is made in *bolts*; and the qualities are numbered from No. 1, which is the strongest and is used for storm sails, to No. 8, which is used for the smallest sails, as small studding sails, &c., which the seamen commonly call *flying kites*. The cloths in a square sail are seamed vertically; in a fore-and-aft sail they are parallel to the after leech. In this way the strain of the sheet diffuses itself over the canvas both along and across the cloths. Discussions have, however, arisen as to the best mode of seaming. When a seam opens, the sail often splits. Captain Cowan took out a patent for *horizontal* seaming; he remarks (*Essay on the Construction of Sails, &c.*), that such sails when they split remain full, and are less liable to blow away, and that they also were found to last much longer. The plan, however, has not been approved. *Diagonal* seaming, which has also had its advocates, is defective in principle; for it must bring the strain of a sheet either on a single cloth, or entirely across the stitches.

Sails take their names from the mast, yard, or stay upon which they are stretched. Thus, the principal sail extended upon the main mast is called the *main-sail*; the next above, which stands upon the main top-mast, is the *main-top-sail*; above which is the *main top-gallant-sail*; and above all, the *main royal*. In like manner, there are the *foresail*, the *fore top-sail*, the *fore top-gallant-sail*, and the *fore royal*, although the square foresail is very rarely used, from the circumstance that it would take the wind out of all the jibs; and similar appellations are given to the sails supported by the *mizzen* or after mast. The *main stay-sail*, *main-top-mast stay-sail*, &c., are between the main and fore masts; and the *mizzen stay-sail*, *mizzen-top-mast stay-sail*, &c., are between the main and mizzen masts. These are, however, employed only in dead calms and under exceptional circumstances. Between the foremast and bowsprit are the *fore stay-sail* (commonly called the *fore-sail*), the *jib*, and sometimes a *flying jib* and *middle jib*; and the *studding sails* are those which are extended upon booms run out beyond the arms of the different yards of the main mast and fore mast.

To *make* sail, is to set sail. To *shorten* sail, is to take in some sail by furling or reefing. To *loose* sails, is to spread or hang out the sails that had been furled, either to air them, or for the purpose of setting afterwards. To *strike* sail, is to lower the yard or gaff of a sail when set, in token of salute. Furling and reefing sails are performed either by men going along the yard to which the sail's head is attached, and so drawing the sail up and binding it to that yard, or by Cunningham's Patent, described below, under which these operations can be performed from the deck.

The common theory of sails which assumes the impact of columns of air is radically defective; for it is a fact familiar to sailors that the reef points, or any light stuff by accident in the same situation, hang vertically in the hollow of the sail, as in a calm, thereby proving that the sail is filled with a mass of air, quiescent or nearly so, and maintained in a state of statical pressure; whereas if the common theory were true, the points would lie flat to the canvas, as weeds are pressed against the bank of a stream. Hence

it follows that there is a certain extent of hollow or *belly* which increases the effect of the sail. It of course adds to the effect of sails to wet them, by swelling the threads and closing the pores: this practice is often resorted to in calm weather. In recent years several systems have been attempted for furling and taking in sails without the necessity for sending men aloft—a dangerous duty in foul weather. The invention of Mr. Cunningham, R.N., has attained most celebrity. In this, the yard to which the sail is bent is made to revolve in its slings by means of ropes upon the deck, and to wind or unwind the sail upon it. The plan involves a vertical division in the centre of the sail, and, moreover, makes it necessary to lessen the number while increasing the length of the sails on each mast. The practical experience of this system has not yet been sufficient to allow of any decisive opinion on its merits; but, while it is certain to encounter much prejudice from naval men, who cling with singular tenacity to old customs, it is incontrovertible that it saves hands, and therefore diminishes the cost of practical navigation.

Sailing. In Navigation, the art of directing a ship on a given line laid down in a chart. It is called *plane sailing* when the chart is constructed on the supposition that the earth's surface (or rather the surface of the ocean) is an extended plane; and *globular sailing*, when the chart is a globular chart, or constructed on the supposition that the earth is a sphere, the ship being then supposed to be sailing on the arc of a great circle. [GREAT CIRCLE SAILING; NAVIGATION.]

Sailing Order or **Order of Sailing.** Any determinate order preserved by a squadron of ships. It usually implied, in the days of sailing fleets, one, two, or three parallel columns; but it is at the disposition of the admiral.

Sailor. On Shipboard, one who is making a long sea voyage other than his first; and who is qualified to go aloft and tend the sails. A sailor is not necessarily a seaman.

Sainfoin or **Saintfoin** (Fr.). The *Onobrychis sativa*, a plant of the family *Leguminosæ*, and cultivated as a very wholesome fodder. It will not thrive well except when the soil or subsoil is calcareous, and consequently it is rarely met with, except on the Cotswold Hills, and on the chalk soils of Dorset, Hants, Wilts, Sussex, Kent, &c. It generally remains for eight or ten years, a much longer period than it does in France. The first growth is made into hay, the after crop being eaten by cattle; it is also well adapted for *soiling*.

Saint George's Ensign or **The White Ensign.** The distinguishing badge of ships of the Royal Navy. It consists of a red cross on a white field with a union jack in the upper quarter next the mast. The St. George's flag is the admiral's sign of presence and command. An admiral carries it at the main, a vice-admiral at the fore, and a rear-admiral at the mizzen. It resembles the ensign, but is much smaller, and the union jack is wanting.

Saint John of Jerusalem, Knights of. A military order of religious persons. They derived their name from a church and monastery dedicated to St. John the Baptist, founded at Jerusalem about 1048 by merchants from Amalfi, the brotherhood of its members being devoted to the duty of taking care of poor and sick pilgrims. The order was instituted as a military brotherhood by Raymond du Puy, its principal, early in the twelfth century. It was divided into three ranks—knights, chaplains, and servitors; and in its military capacity it was bound to defend the church against the infidels. It held various possessions and settlements in different parts of the East. In the thirteenth century, being driven from Palestine, the knights of this order fixed their principal seat first in Cyprus, and afterwards at Rhodes, where they remained from 1309 to 1522, when the island was captured by Solyman II. After several changes of settlement, they were fixed in 1530 by Charles V. at Malta and its dependent islands; whence they took the name of Knights of Malta. Here they maintained themselves until 1798, when the island was taken by Napoleon. The order, however, continued to subsist, notwithstanding the loss of its sovereign possessions both in Malta and in Tuscany. Before the French revolution the number of knights was estimated at 3,000. The temporal powers of the order were chiefly concentrated in the hands of the grand master; but he was, in fact, controlled by the governors of the eight languages. These were, of Provence, Auvergne, France, Italy, Aragon, Germany, Castile, and England. The lands were divided into priories, commanderies, and bailliages. The spiritual power was exercised by the chapter, consisting of eight ballivi conventuales. The knights were under the rules of the order of St. Augustine; but Protestants were not bound to celibacy. They were required to be necessarily of good descent; but those whose proofs of noble ancestry were unquestionable were termed *cavalieri di giustizia*, while others who could not show such proofs might be admitted on account of their merits as *cavalieri di grazia*. [HOSPITALLERS.]

Saint Simonians. In Political Philosophy, the name given to the followers of Claude Henri, count de St. Simon. [SOCIALISM.]

Saints (Lat. sancti, *holy persons*). Pious men, who, according to a custom early prevalent among Christians, were commemorated with honour after their death in the services and ceremonies of the church. This distinction was originally applied to the apostles and eminent martyrs and confessors, whose places of burial were regarded with pious affection by the faithful in the neighbourhood, and memorials or relics of whom were carefully cherished. The observance of particular days in honour of the saints was also a very early custom, and from this practice the cultus of the saints was

developed. Their intercession was supposed to have power with God, and individuals put themselves under the especial patronage of one or more amongst the number, which in later times was vastly augmented. The assertion that miracles were performed at their tombs and by their relics, led not unfrequently to the greatest rivalry and contention between the votaries of the shrines of different saints, and sometimes those of the same. For the hierarchy of the saints, see Milman, *Latin Christianity*, book xiv. ch. ii. [CANONISATION.]

Saker (for the derivation of this word, see MUSKET). A cannon of the sixteenth century. Tartaglia, who dedicated a work on gunnery to Henry VIII., gives a table of ordnance including 6½-pounder and 8-pounder sakers. Fosbroke (*Encyclopædia of Antiquities*) gives a table of Ordnance of Queen Elizabeth's time, including the saker, throwing a 5¼ lb. ball, and of 3¼ inches calibre. On a gun 7 feet 9 inches long, of 3·75 inches calibre, in the Museum of Artillery at Woolwich, occurs this inscription, 'IHON and Robert Owyn, bretheryn, made thys sacar, weying IZIZ. Anno Dni. 1538.'

Sal Alembroth. The hydrargo-chloride of ammonium. A compound of sal ammoniac and corrosive sublimate.

Sal Ammoniac. Muriate of ammonia; hydro-chlorate of ammonia; chloride of ammonium. A compound of ammonia and hydrochloric acid. Its name is derived from the temple of Jupiter Ammon, in Egypt, where it was originally made by burning camels' dung: it is now largely manufactured in this country. [AMMONIA.]

Sal de Duobus (Lat.). An ancient chemical name applied to sulphate of potash.

Sal Gem. Common salt.

Sal Mirabile (Lat.). Glauber's salt. Sulphate of soda.

Sal Perlatum (Lat.). A term applied by old chemical writers to the rhombic phosphate of soda.

Sal Prunella. Nitrate of potash fused into cakes or balls. The latter were sometimes coloured blue.

Sal Seignette. Tartrate of potash and soda. [ROCHELLE SALT.]

Sal Volatile (Lat.). Carbonate of ammonia. The term is often applied to a spirituous solution of carbonate of ammonia flavoured with aromatics, as in the *compound spirit of ammonia* in the *Pharmacopœia*.

Salade (Fr.) or **Sallet.** A piece of armour for the head, in use in the fifteenth century.

Salamander (Gr. σαλάμανδρα). The name of a genus of Batrachian reptiles, now limited to the terrestrial species of long-tailed Caducibranchiates, or those which lose their gills before arriving at maturity, but retain their tails. This appendage is changed in the progress of growth in the true salamander from a compressed to a rounded form. The female brings forth the young alive, which are hatched in the oviduct; and the sexes frequent the water at the season of reproduction. [BATRACHIA; TRITON.]

Salamstein or **Salamstone.** The name given by Werner to the blue or Oriental Sapphire from Ceylon.

Salep (Arab. Sahleb). The prepared roots of the *Orchis mascula*, *latifolia*, and *Morio*, as well as of other tuber-bearing species of the Orchid family. These roots consist principally of bassorin, with a small quantity of starch, and are dried and preserved for use as an article of food.

Salic Law. The law of that community of the nation of Franks which inhabited the country between the Meuse and the Rhine—the law of the Ripuarian Franks governing those who dwelt between the Rhine and the Loire. The origin of the name Salian, given to this portion of the Franks and their law, is uncertain; some derive it from the river Saale, in Saxony, on the banks of which the Salii are supposed to have been settled before the period of their migration westward. The body of law in question was republished and reformed by Charlemagne in 798, and is still preserved, both in the earlier and in the remodelled shape. The most celebrated portion of it is contained in the title 62. *De Alode*, where it is declared that 'no portion of the inheritance in Salic land (terra salica) can fall to females; but that the whole must pass to the males.' What those lands were which are intended by the term Salic, has afforded room for infinite discussion among French antiquaries. It is supposed by Ducange that they were those lands which were acquired by Franks at the period of the conquest, and held by military service only. But it is argued by some that the exclusion of females was only to take place where males were to be found in the same degree of kindred to the ancestor. However this may be, the fundamental law which excluded females from succession to the crown of France received, in very early times, the appellation of the Salic law, and was supposed by her lawyers to be derived from the provisions of this ancient code. This custom prevailed from the earliest times, as we learn from Tacitus, among the Germanic tribes. The first occasion on which it was publicly canvassed in France was in 1316, when Jeanne, the daughter of Louis Hutin, was excluded from the crown in favour of Philip V. her uncle. In 1328 it was contested by Edward III., who claimed by a title prior to that of Philip of Valois, if females were admissible; Edward being the son of Isabella, sister of Louis Hutin. From this pretension arose the wars between England and France, which occupied the whole of the following century. In 1593 the famous arrêt of the parliament of Paris was pronounced, by which all treaties made to transfer the crown to a foreign dynasty were declared null, as contrary to the *Salic* and other fundamental laws. The same law has been recognised in all countries of which the crown has devolved upon the royal house of France, and formed the foundation of those pretensions of the Infant Don Carlos (Bourbon) to the throne of Spain which caused the

great Spanish civil wars of this century. It was also considered as established in those great fiefs of the crown of France which had been granted to princes of the blood by way of apanage; and by this means, on the death of Charles duke of Burgundy, leaving a daughter only, the dukedom of Burgundy proper reverted to Louis XI. as a male fief. (*Mém. de l'Acad. des Inscr.* vol. xx.; Meyer's *Origines Judiciaires*; Hallam's *Middle Ages*.)

Salicaceæ (*Salix*, the principal genus). A natural order of Achlamydeous Exogens, distinguished by a two-valved capsule, and numerous seeds tufted with long hairs. The genus *Salix* comprehends the plants called Osiers, Sallows, and Willows, and is of great economical value, not only for the purposes of the basket-maker, but because several species have a bark which has been found by Davy to contain as much tannin as the oak. A crystallisable principle called *salicin* has been obtained from *Salix Helix* and others, which, according to Magendie, arrests the progress of fever as efficiently as the sulphate of quinine. The Poplars, Aspens, and Abele trees also form a part of this order.

Salicin (Lat. salix, *a willow*). ($C_{26}H_{18}O_{14}$.) A crystalline substance extracted from the bark of the willow. Its solutions have a bitter taste: they are lævogyrate with reference to polarised light. Salicin is characterised by the deep red colour which is produced when the crystals are moistened with strong sulphuric acid. When salicin is boiled with dilute sulphuric acid, glucose and saligenin are produced. When distilled with bichromate of potash and dilute sulphuric acid, salicylous acid or hydride of salicyl ($C_{14}H_5O_4$, H) is obtained in the distillate. This is identical with the essential oil of Meadow-sweet (*Spiræa Ulmaria*). When fused below redness with three parts of hydrate of potash, a salicylate of the alkali is obtained, from a solution of which salicylic acid is precipitated by the addition of hydrochloric acid. A solution of a *salicylate* is characterised by its striking a *violet*-blue colour with a persalt of iron. Certain insects which feed upon willow bark, oxidise salicin in their bodies; and if placed on paper impregnated with a persalt of iron, and irritated, they eject a liquid which produces a blue spot on the paper. The oil or essence of winter-green (*Gaultheria procumbens*) is a salicylate of the oxide of methyl (C_2H_3O $C_{14}H_5O_5$). It has a strong agreeable odour, and acquires a violet colour on the addition of a persalt of iron.

Salicoques. The French term for the family of Macrourans or long-tailed Crustacea of which the shrimp (*Crangon vulgaris*) is the type.

Salicylic Acid. An acid obtained by the action of fused potassa on salicin. [SALICIN.]

Salient (Lat. salio, *I leap*). In Heraldry, a term used to describe a beast when represented as leaping or springing.

Salient Angle. In Fortification, an angle of which the angular point projects outwards from the work. It is the reverse of a RE-ENTERING ANGLE.

Salient Angle of a Polygon. An angle which projects *outwards*. If an angle of a polygon be defined as the quantity of turning required in order to cause one side to coincide with the next after *sweeping across the polygon itself*, then any angle of a polygon will be *salient* which is less than two right angles; an angle greater than two right angles would then be termed a RE-ENTERING ANGLE.

Salient Places of Arms. In Fortification, enlarged spaces left by the rounding of the counterscarp opposite the salients. They are intended for the assembly of troops for sorties or defence.

Salientia (Lat. part. of salio, *I leap*). The third order in the Mammalogical system of Illiger, including the Marsupial genera *Hypsiprymnus* and *Halmaturus*, or the potoroos and kangaroos, whose progression is by successive leaps.

Saliferous Rocks. Rocks of the Triassic series containing deposits of common salt in England were formerly thus designated. The name is now not generally used, as many of the salt-bearing rocks are Tertiary.

Salifiable Base. This term, which is of frequent occurrence in chemistry, is applied chiefly to those metallic oxides which combine in definite proportions with the acids, so as to form distinct acids. Ammonia and the vegeto-alkalis are also, upon the same principle, salifiable bases.

Salii. The Roman flamens, or peculiar priests of Mars. They were twelve in number, and guarded the ANCILE, or sacred shield of Mars.

Salinometer. An instrument for measuring the quantity of salt that may be in solution in the water of a steam boiler, which is indicated by the specific gravity of the water. Common sea water contains $\frac{1}{33}$ of salt, and the water in the boiler should never be suffered to attain a degree of saturation above that represented by $\frac{2}{33}$ of salt, or *two salt waters* as it is called.

Saliva (Lat.). The fluid secreted into the mouth by the salivary glands; its principal use is to lubricate the parts, and to assist in rendering the food of a proper consistency to be swallowed.

Salivation. The excessive flow of saliva produced by the continuous use of mercury and of some other remedies. Cases of spontaneous salivation have occasionally been noticed, in which the discharge and fœtor have led to the mistaken conclusion that mercury had been used freely.

Salix (Lat. *a willow*). A genus of plants consisting of numerous species, all either trees or bushes, occurring abundantly in the cooler parts of the northern hemisphere. Some, like *S. alba*, acquire the dimensions of the largest forest trees; others are lost among the grass with which they grow, as *S. herbacea*. They are the last kind of ligneous plants that dis-

appear before the rigours of an arctic climate, the only tree found on Melville Island, nine inches high, having been a willow (*Salix arctica*). Few extend into warm regions, the *Salix babylonica*, or Weeping Willow, being the best known instance. Their timber, when they form any, is light, tough, soft, and unfit for purposes of construction; it is chiefly used for turnery, and for coarse in-door purposes. Many species have long flexible shoots, and are called *Osiers*, under which name they are extensively employed by the workers in wicker; others are not flexible, but form small trees or rough bushes, named Sallows. The latter, called *Saules marceaux* by the French, yield the best kind of charcoal for military purposes; they are all, however, burnt for the preparation of this substance. The bark of *S. Helix*, *fragilis*, *pentandra*, and others, has been found useful in intermittent fevers, which are most common in the low marshy places where salices abound. The species intermix very freely, forming mules and hybrids, which have led botanists to create a prodigious number of false species.

Sallow. [SALIX.]

Sally Port. In Fortification, an opening cut in the glacis, through which a passage leads by a ramp from the terreplein of the covered way to the exterior.

SALLY PORT. In Naval language, a landing place in a harbour at which the boats of men-of-war, but no other boats, are allowed to land. It is also the name for the opening in the quarter of a fire-ship by which the crew escape after setting her on fire.

Salmon (Lat. salmo). The excellent and highly valuable fish so called in England is the *Salmo salar* of Linnæus, the *Salmo nobilis* of Pallas. Specimens of this species have been examined, compared, and determined, from French, Danish, Dutch, as well as British rivers, by Dr. Günther, of the British Museum.

The normal locality of the salmon is at the mouth or estuary of the larger rivers, which, in the season of sexual excitement, they ascend, sooner or later in the year, according as circumstances may influence their coming into breeding condition. At first they ascend only so far as the tide wave reaches, and retire with the ebb; but as the quantity of roe and milt increases, the instinct which teaches the fit locality for oviposition becomes more imperative, and there are few natural obstacles which the salmon fails to overcome in its endeavour to reach it.

The great value of the fish renders an accurate knowledge of it, under the disguise of its immature form and markings, of the highest importance; but the difficulties which attend the observation of the migratory inhabitants of the water have only very lately been overcome in the present instance. The proof that the small salmonoid fish, called the *parr*, is, as many naturalists had suspected, the young of the salmon, has been elicited by the careful and repeated observations and experiments of Mr. Shaw of Drumlanrig, of which the following condensed account is taken from the *Transactions of the Royal Society of Edinburgh*.

In the river Nith, Dumfries, the salmon oviposits in the month of January. On January 10, Mr. Shaw observed a female salmon of about 16 lbs. weight, and two males of at least 25 lbs., engaged in depositing their spawn. The spot which they had selected for that purpose was a little apart from some other salmon which were engaged in the same process, and rather nearer the side of the stream, although still in pretty deep water. The two males kept up an incessant conflict during the whole of the day for possession of the female, and in their struggle frequently drove each other almost ashore, and were repeatedly on the surface, displaying their dorsal fins and lashing the water with their tails.—The female throws herself at intervals of a few minutes upon her side; and while in that position, by the rapid action of her tail she digs a receptacle in the gravel for her ova, a portion of which she deposits, and again turning upon her side she covers it up by the renewed action of the tail; thus alternately digging, depositing, and covering the ova, until the process is completed by the laying of the whole mass, an operation which generally occupies three or four days. The embryo fish, conspicuous by the two dark eye-specks and the vascular vitelline sac, presented some appearance of animation in the ovum on February 26, i. e. forty-eight days after having been deposited; and on April 8, or ninety days after impregnation of the ova, the young were excluded. The head is large in proportion to the body, which measures five-eighths of an inch in length; the vitellicle is two-eighths of an inch in length, and resembles a light red currant; the tail is margined like that of the tadpole, with a continuous fin running from the dorsal above to the anal beneath. The vitelline sac and its contents are absorbed by May 30, or in about fifty days, until which time the young fish does not leave the gravel. The terminal fringe-like fin now begins to divide itself into the dorsal, adipose, caudal, and anal fins; and the transverse bars on the sides of the body make their appearance. At this period the young salmon measures an inch in length, and is very active, and continues in the shallows of its native stream till the following spring, when it has attained the length of from three to four inches, and is called the *May parr*: they now descend into deeper parts of the river, where the weaker fish remain over the second winter. In April, the caudal, pectoral, and dorsal fins assume a dusky margin; the lateral bars begin to be concealed by a silvery pigment; and the migratory dress, characteristic of the salmon fry or smolt, is assumed. The fish now begin to congregate in shoals, and to migrate seaward. They return in autumn of a size proportionate to the length of their stay in the estuary. A smolt may not exceed two ounces weight when it goes to sea; after a few months it may have grown to a *grilse* of eight or ten pounds weight. At two

years and eight months old, it becomes a *salmon* of from twelve to fifteen pounds weight.

The full-grown salmon averages a weight of between 25 lbs. and 35 lbs.; but instances are recorded of their attaining to 55 lbs., 60 lbs., 70 lbs., 74 lbs., and 83 lbs. The last-cited weight was that of a female salmon, which came into the possession of Mr. Groves, fishmonger, in Bond Street, about the season of 1821; it was a short fish for the weight, but of very unusual thickness and depth. When cut up, the flesh was fine in colour, and proved of excellent quality. [FISHERIES.]

Salmonoids. A family of soft-finned Abdominal fishes, of which the salmon is the type, having their upper jaw formed in the middle by the intermaxillary, and at the sides by the maxillary bones, both of which support teeth; they are also characterised by a posterior small adipose dorsal fin, and the body is covered with regular cycloid scales. They pass, by almost imperceptible gradations, into the Clupeoid or herring family, with which they have been united by M. Agassiz, to form a common group termed *Halecoids*. Those species of Salmonoids which, like the Clupeoids, inhabit the sea, not only approach the land, but ascend the rivers nearly to their source, in order to deposit their ova.

Saloon (Ital. salone). In Architecture, a large state apartment; or a great hall, usually running up through two stories of a house. The term *salon* is also applied to the réunions of the French capital.

Saloop. [SASSAFRAS.]

Salop. [SALEP.]

Salp (Lat. salpa, *a stock-fish*). A name applied to a genus of soft-shelled or tunicated Acephalous Molluscs, which float in the sea, protected by a transparent gelatinous coat, perforated for the passage of water at both extremities.

Salpinx (Gr. σάλπιγξ, *a trumpet*). The Eustachian tube, or channel of communication between the mouth and ear.

Salsafy. The *Tragopogon porrifolius* of botanists, the fleshy roots of which form a wholesome and nutritious esculent. The plant is a biennial, indigenous to Britain and the continent of Europe, and has a long fusiform root, full of milky juice, on which its salutary qualities depend. In colour it resembles the parsnip, of which it has also nearly the flavour, but is more agreeable. It ranks as one of the most salubrious of culinary vegetables, being antibilious, cooling, deobstruent, and slightly aperient; but although it is deservedly esteemed as excellent, it is nevertheless inferior to *Scorzonera* in these properties.

Salsola (Lat. salsus, *salt*). A genus of *Chenopodiaceæ*, the species of which are distinguished by the name of Saltworts. They are found only on the sea-coast or in salt marshes, and are of weedy character; but the ashes of some of them, e.g. *S. Kali* and *S. Soda*, yield an impure carbonate of soda known under the Spanish name *Barilla*, which was formerly an article of considerable commercial importance. Large quantities of it were at one time annually imported into the United Kingdom from the Canary Islands, Spain, and other parts of the South of Europe, and employed in soap and glass-making; but since the introduction of soda manufactured from common salt as a commercial article, the imports have greatly decreased, though about a thousand tons of barilla and other alkalies are still annually imported, mostly from the Canary Islands and the Two Sicilies. For the preparation of barilla these plants are dried in heaps like hay, and afterwards burnt upon a rude grating constructed over a large hole, into which the semifluid alkaline matter flows, and is there left to cool and solidify. *Kali* is the Arabic name for the ashes of these soda-plants, and the term *alkali*, applied by chemists to soda, potassa, and similar substances, appears to be derived either from *Kali*, with the Arabic article *al* prefixed or from a corruption of *sal* (salt) and *Kali*.

Salt (Lat. sal, Ger. salz, Gr. ἅλς). This term, though in ordinary language limited to common salt, or sea-salt, is applied in chemistry to all combinations of acids with alkaline or salifiable bases. The term has also been extended to certain binary combinations of chlorine, iodine, bromine, and fluorine with the metals; and these have been called *haloid salts*, inasmuch as modern chemistry has taught us that sea-salt belongs to this class. Certain definite combinations of the sulphides with each other have been called *sulphur salts*; but the appellation of *double sulphides* is more commonly applied to such compounds.

Sea-salt is a compound of one equivalent of sodium = 23, and 1 of chlorine = 35·5; its equivalent, therefore, is (23 + 35·5) = 58·5: and it is a chloride of sodium. The circumstances which gave rise to the notion of its containing muriatic acid and soda, and being therefore a muriate (hydrochlorate) of soda, will be apparent by reference to the article MURIATIC ACID.

Salt is a necessary of life, and one of the most important British minerals. It is procured in immense quantities, both from fossil beds and brine springs, in Cheshire and Worcestershire. Before the discovery of the fossil beds during the sixteenth century, and subsequently, a good deal of salt continued to be made by the evaporation of sea-water in salt-pans, at Lymington and many other places; but the works at these places are now all but abandoned; while not only has the quality of salt become greatly improved, but, instead of being imported as formerly, it is now largely exported. The consumption of Great Britain alone, exclusive of Ireland, amounts to about 180,000 tons; the foreign exports amount to about 300,000 tons per year, of which the United States, Canada, the Low Countries, Russia, Prussia, and Denmark are the chief consumers. Down to the year 1823, a tax of 15*s*. per bushel, or about thirty times the original cost price of the article, was imposed on salt; but in that year it was reduced to

2s., and two years subsequently was totally repealed. During the existence of the duty, the retail price of salt was 4½d., it is now ½d. per lb.

In ancient Rome, salt was subjected to a duty, *vectigal salinarium*; and it has been heavily taxed in modern states. The GABELLE, or code of salt laws formerly established in France, was most oppressive. From 4,000 to 5,000 persons were calculated to have been sent annually to prison and the galleys, for offences connected with these laws, the severity of which had no inconsiderable share in bringing about the revolution.

Salt Deposits, Salt Springs. Very large accumulations of salt occur in certain rocks without reference to geological age. They are, for the most part, distributed in very limited areas. The principal salt deposits in England are in Cheshire and adjoining counties, in beds of the new red sandstone series. In the Tyrol there are large deposits, of similar geological age. At Cardona, in Spain, in the lower tertiary rocks, is a magnificent developement of rock-salt, and in Poland and Hungary there are enormous masses, of middle tertiary age. Salt springs are common in carboniferous rocks, both in England and America. In other places, as in the Dead Sea, there is salt now in course of deposit.

Salt is usually associated with marls, sandstones, and gypsum, and appears to have been generally accumulated by the evaporation of sea-water, which contains a quantity of materials left behind under such circumstances. The salts collect, and in course of time many of them enter into new combinations; that which is most valuable to man, the chloride of sodium, forming into beds and rocky masses.

Afterwards, if water obtain access to such beds, they are partially dissolved, and the water may come to the surface as brine springs, which are not unfrequent where rock-salt is not known.

Salt Gardens (Fr. salins). A name applied to the evaporating surfaces employed on the south and west coasts of France for the preparation of common salt from sea-water. They are also called *salterns*. The salt gardens are usually erected close to salt marshes, which are kept filled by the sea. The marshes act as a reservoir for the salt gardens, and also possess the advantage of concentrating the saline water by spontaneous evaporation. During the summer months the water from the marshes is allowed to flow very slowly, and in layers not more than five or six centimètres deep, over a number of square basins. The current of water is so regulated that when it arrives at the last of these basins it is on the point of crystallising; it is then run into smaller basins, where the chloride of sodium is deposited. After the chloride of sodium has been separated, the mother liquors are employed for the preparation of chloride of potassium, chloride of magnesium, sulphate of magnesia, and sulphate of soda. Salterns were formerly common along the south coast of England, where a few may still be seen in operation.

Salt Lakes. In the article on the DEAD SEA an account is given of the very remarkable depressed salt lake system of Palestine. It is not, however, necessary that a lake should be depressed below the sea level to be thus loaded with salt. The lake of Oroomiah, in the north-west of Persia, eighty miles long and thirty miles broad in some places, is nearly 4,000 feet above the level of the Black Sea. This is also a salt lake, but nearly the whole saline contents are common salt, and there remain in the water both sulphate of lime and sulphate of magnesia. In this case, however, the salt is derived from the soil, and not deposited upon it; the whole surrounding neighbourhood, which is flat, abounding everywhere with rock-salt. These deposits of rock-salt, perhaps originally produced like those of the Dead Sea, are now being redissolved by fresh water poured over them periodically and draining into this lake, from whose surface a large and constant evaporation takes place.

The Elton lake, connected with a group of very important brine pools in the lowest part of the great depression of the Aralo-Caspian plains, is another example of the formation of rock-salt, closely resembling the Dead Sea. This lake measures thirteen miles by eleven, or thereabouts, and is nineteen feet below the sea level; but it is part of a very wide tract of country, nearly flat, in which are a vast multitude of smaller lakes, also loaded with salt. Its waters vary much in contents in different parts of the year, especially in the proportion of common salt, but there is always from 10 to nearly 20 per cent. of chloride of magnesium. This is therefore a concentrating mother liquor depositing salt regularly every summer, and receiving other additions in other parts of the year. Here, as in the Dead Sea, a regular deposit is going on, which is not, however, so calculated to produce continuous and thick beds of rock-salt, although in course of time, when the proportion of the chloride of magnesium is larger (and it is constantly increasing), the result will be a much more rapid deposit of common salt, and the accumulation in the mother liquor of similar mineral ingredients.

There is no need to give the history of other depressed or elevated salt lakes, in order to show that the production of salt beds in the one case, or their consumption in the other, is the consequence of laws which, acting from time immemorial, have added continually to the mineral wealth of many parts of the world.

Salt of Lemons. Binoxalate of potassa is usually sold under this name, and is used for the removal of iron-moulds and other stains from linen.

Salt Mines. The deposits of rock-salt in the county of Cheshire in England, and in various parts of the continent of Europe

and elsewhere, are often capable of extraction by simple modifications of the ordinary processes of mining. Salt is also largely obtained from brine springs whose source is in deposits of similar kind. The methods of mining vary naturally according to the circumstances of the deposit.

The salt mines of Cheshire are intended to remove the salt from two irregular masses, whose thickness is in some places as much as a hundred feet. These masses are parts of a large group of saliferous marls and sandstones, whose area is not less than 150 square miles, but the thick deposits are very much smaller. These deposits are in the Triassic series. Others of the same nature occur at Cardona, near Barcelona in Spain, others in the Tyrol, others in Poland, and all these are in similar marls and sandstones. The method of working closely resembles that adopted in removing thick coal. [MINING.] In the Tyrol, large cavities in the salt-bearing rocks are filled with water, which is allowed to become saturated, and is then pumped off and evaporated.

Salt of Sorrel. A name frequently applied to the binoxalate of potash. [OXALIC ACID.]

Salt, Spirit of. [MURIATIC ACID.]

Salts. The term *salt*, as a noun, originally belonged to common sea-salt only. Domestically it does so still. In Chemistry, it is now conventionally applied to any well-defined solid substance containing two or more radicals. The radicals may be simple or compound, inorganic or organic. *Haloid salts* contain two simple inorganic radicals, as in chloride of sodium and iodide of potassium. *Oxysalts* consist of two compound organic or inorganic radicals which contain oxygen, as in sulphate of quinine or nitrate of potash. *Sulphur salts* are oxysalts in which oxygen is replaced by sulphur, as the sulpharsenite or sulphide of sodium. *Supersalts* are those containing excess of negative constituent, as superphosphate of lime.

Saltatory (Lat. saltatorius, from salto, *I leap*). In Zoology, the extremities of an animal which by their form and proportions are adapted for leaping, are called *pedes saltatorii*; as the hind legs of the kangaroo, cricket, &c.

Salterus. [SALT GARDENS.]

Saltigrades (Lat. saltus, *a leap*, and gradior, *I walk*). The name of a tribe of spiders which seize their prey by leaping upon it from a distance.

Saltire (Fr. sautoir). In Heraldry, an ordinary in the form of a cross of Saint Andrew: formed by two bends, dexter and sinister, crossing each other. Charges having length (swords, bâtons, &c.) placed in the direction of the saltire, are said to be borne *saltire-wise*.

Saltpetre. [NITRE.]

Salute (Lat. saluto, *I greet*). In the Military and Naval services, a mark of respect performed in different ways, according to circumstances. Salutes are fired from cannon according to instructions laid down in the Queen's regulations. The number of guns marks the rank of the personage saluted. A royal salute consists of twenty-one guns. Ambassadors are saluted with nineteen guns; and so the number decreases, to the salute for consuls, captains of the navy, &c., which is of seven guns. A foreigner's salute is returned gun for gun.

Troops under arms salute with their rifles or swords; staff officers not drawing their swords salute with the hand, as do soldiers when unarmed. The theory of the salute is founded probably on the temporary disarmament of the person saluting. Thus, in the naval salute, the discharge of the guns renders the ship for the time helpless; and in the military salute each of the various movements disqualifies the performer both for attack and defence.

Salvadoraceæ (Salvadora, one of the genera). A small natural order of Perigynous Exogens, of the Echial alliance in Lindley's arrangement. The few known species are found in India, Syria, and North Africa; and the group is specially known by its regular symmetrical flowers, its naked stigma, and its solitary fruit. The most interesting plant of the order is *Salvadora persica*, which according to the researches of Dr. Royle is the Mustard-tree of the New Testament. This view, however, is not universally adopted, some distinguished botanists of the present day regarding it as more probable that our common black mustard, which attains considerable size in Palestine, is the plant referred to in the Gospels.

Salvage (Fr. from Lat. salvus, *safe*). In Mercantile Law, salvage is defined to be a compensation to be made by the shipowner or merchant to other persons by whose assistance the ship or lading may be saved from impending peril, or recovered after actual loss. Salvage may become due: 1. On rescue from the perils of the sea. In this case, the salvor, or rescuer, has a lien on the goods preserved until a recompense is made him. The amount of this recompense may be fixed by a jury; but if the salvage happen at sea, or between high and low water mark, the court of admiralty has also jurisdiction to fix the amount on suit brought; and by statute, summary powers for the same purpose are given to inferior officers in certain cases. 2. On rescue from the hands of enemies. In this case, the old law was, that if a ship was retaken from enemies before it was taken home or condemned by the captor, the original owner could recover her on payment of salvage to the recaptor; but if retaken at a later period, she became lawful prize to the recaptors. But by 13 Geo. II. c. 4, s. 18, and other statutes, the right of the original owner has been extended to all cases of recapture. See now 17 & 18 Vict. c. 104, and 18 & 19 Vict. c. 91.

Salvatella (Lat. salvus, *safe*). A vein of the arm terminating in the fingers. It was

formerly regarded as having peculiar influence on the health when opened.

Salvia. A genus of useful as well as ornamental plants, belonging to the Labiate order. Many of the species, as *S. splendens, cardinalis, gesnerifolia, patens,* and others, are extremely showy greenhouse plants; and some, as *S. hians, candelabrum, pratensis,* &c., are gay, hardy perennials. *S. officinalis* is the well-known garden herb, called Sage, cultivated everywhere for its bitter and aromatic properties.

Sama Veda. [Veda.]

Samanæans. A sect of Indian philosophers. The name is probably Oriental; the word schamman, in India, signifying a philosopher. The Samanæans are particularly distinguished, by those who mention them, from the Brahmans. Saint Jerome and Clement of Alexandria represent them as priests of Buddha; and the same name appears in the *Cha-Men* of the Chinese, and *Sammono-Codom* of Siam. [Buddhists.] There is a memoir on the subject by M. de Guignes. (*Mém. de l'Acad. des Inscr.* vol. xxvi.; *Hist. de l'Acad. des Inscr.* vol. xxxi.; and *Mém.* vol. xl.)

Samara (Lat. *an elm-seed*). In Botany, an indehiscent superior fruit, being a few-seeded, dry nut, elongated into wing-like expansions; as in the fruit or *key* of the ash-tree, &c. From this root is formed the word *samaroid*, expressing a resemblance to a samara.

Samaritans. The inhabitants of the city and district of Samaria to the north of Judea. This city, built by King Omri, was the capital of the kings of the ten tribes of Israel. After these had been carried into captivity, it is believed by some that a new population became gradually settled in Samaria, composed partly of a remnant of the old, partly of strangers; by others, that the country was entirely desolated, and that Esarhaddon settled it anew with strangers, especially Cuthites, thought to be of Scythian origin, who afterwards learned the Jewish religion. The Samaritans thus formed a kind of mixed nation, adopting to a great extent Jewish belief and practices. They professed belief in the Pentateuch, but they maintained that Abraham and Jacob had erected an altar on Mount Gerizim in their country, and commanded sacrifice to be made there. Nevertheless, no idolatrous practices are imputed to them; and it was probably their spurious origin which excited against them the jealousy and affected contempt of the Jews, to which many passages of the New Testament so pointedly refer.

Samarskite. A rare mineral composed of a mixture of niobic acid, and small quantities of tungstic acid and various bases, chiefly peroxide of uranium, yttria, zirconia, and protoxide of iron. To these last Thorina has lately been added by the analyses of Finkener and Stephens. It is found in flattened and somewhat polygonal grains which are externally dull iron-black and opaque, in the Ilmen mountains near Miask, in the Ural embedded in reddish-brown Felspar. Named after M. von Samarski.

Sambuca (Lat.; Gr. σαμβύκη). An ancient instrument, resembling a harp, the invention of which was attributed to the Syrians and Phœnicians.

From the likeness to this instrument, the name was also applied to a military engine used in scaling the walls of besieged cities.

Sambucus (Gr. σαμβύκη, *an ancient musical instrument*). A genus of *Caprifoliaceæ*, well represented by the Common Elder, *S. nigra*, a tree of rapid growth when young and remarkable for the stoutness of its shoots, which contain an unusual proportion of pith. This being easily removed, the branches may readily be formed into tubes, and on this account the elder was formerly called the Bore-tree. The wood is white and of a close grain, tough, fissile, and easily cut—hence it is used for making skewers and shoemakers' pegs. The leaves have an unpleasant odour when bruised, which is supposed to be offensive to most insects, and a decoction of them is sometimes employed by gardeners to keep off caterpillars from delicate plants. By village herbalists they are employed in making a kind of ointment, and the flowers serve for fomentations, or are made into a medicinal tea; while the berries are the principal ingredient in *elderberry wine*. *S. Ebulus*, or Danewort, is a herb with a nauseous smell and drastic properties.

Samian Earth and Stone. A species of Bole or marl from the island of Samos.

Samp. A preparation of Indian Corn, largely used in the United States.

Samphire (said to be a corruption of Fr. Saint Pierre). The *Crithmum maritimum* of our coasts, the aromatic fleshy saline leaves of which are collected and made into pickle.

Samson's Post. A strong pillar resting on the keelson, and supporting a beam of the deck over the hold, thus helping to keep the cargo in its place. Also a temporary or movable pillar carrying a leading block for various purposes.

Samuel, Books of. Two canonical books of the Old Testament. The first twenty-four chapters of the first book contain all that relates to the prophet Samuel himself, beginning with the government of Eli. The second book, together with the remainder of the first, carries on the history of the Jews to the death of David. It is traditionally said that the prophet Samuel composed the first part, and the prophets Gad and Nathan the remainder. In early times, these two, and the two following books of the Old Testament, were comprehended under the general name of the Four Books of Kings.

Samydaceæ (Samyda, one of the genera). A small order of Hypogynous Exogens, placed by Lindley in the Violal alliance. It possesses slightly astringent properties, and the species of *Casearia* are used medicinally in South America. The plants have dotted leaves, and apetalous hermaphrodite flowers.

Sanchuniathon (Gr. Σαγχουνιάθων). A writer stated by Philon Byblius to have been

born in Berytus and to have lived in the time of SEMIRAMIS; but as Semiramis herself is mythical, this statement does not furnish much evidence for the existence of Sanchuniathon, in which few now will be found to believe. For the motives which probably moved Philon to forge the fragments which go by the name of Sanchuniathon, see Smith's *Dictionary of Greek and Roman Biography*, s.v.

Sanctification (Lat. sanctificatio). In Theology, this word is employed to denote the state of those Christians who, having lost the inclination to vice, have become pure and holy. This state is produced by the special operation of the Holy Ghost, and ensues upon JUSTIFICATION.

Sanctuary (Lat. sanctuarium, from sanctus, *holy*). The innermost chamber of the tabernacle, or temple, among the Jews, in which was kept the ark of the covenant, and which was regarded as the especial residence of the Most High. It is also called the *holy of holies*, and was never entered except once a year, and then only by the high priest on the day of the great expiation of the sins of the people. For the mystical signification of this act, see Heb. ix. 24.

In Christian churches, the part immediately round the altar is called the *sanctuary*, which is supposed in many respects to bear an analogy to that of the Jews.

From the time of Constantine downwards, certain churches have been set apart in many countries to be an asylum for fugitives from the hands of justice. This seems to have been originally intended only to prevent sudden violence, and to give time for the regular administration of the law, and perhaps, in the case of certain delinquencies, for the intercession of the church. But in England, particularly down to the Reformation, any person who had taken refuge in a sanctuary was secured against punishment, if within the space of forty days he gave signs of repentance and subjected himself to banishment. [ASYLUM.]

Sand (A.-Sax. and Ger.; Dutch zand). Finely divided silicious matter constitutes common river and sea-sand. Particles of other substances are often blended with it, and sometimes it becomes calcareous from the prevalence of carbonate of lime. Silicious sand, selected for the manufacture of mortar and other cements, should be freed from all saline matters, not too fine-grained, and somewhat sharp or angular. In the manufacture of glass and of porcelain it should be free from oxide of iron, and other tinging oxides. The fine white sand resulting from the disintegration of soft and pure sandstone is much used, under the name of *silver*-sand.

Sand Pipes. Deep hollows of cylindrical form and very narrow are frequently found penetrating the surface of chalk, and filled with sand and gravel. They are called in Norfolk, where they are most common, sand pipes or sand galls. In France they are known as *puits naturels*. They have been found near Norwich penetrating upwards of sixty feet into the chalk, the larger ones being twelve feet in diameter. They all taper downward and end in a point, and even when close together, and in soft chalk, the walls are not broken through. Generally the sides and bottom are lined with clay, and the central part of each pipe is full of sand and gravel.

It is not easy always to see how such pipes or funnels can have been found. Some may have commenced by the rotatory motion of stones drilling holes in the chalk, but they have probably been continued by the slow action of water containing carbonic acid penetrating into holes made in this or some other accidental way, and perhaps deepened in modern times by the action of humic acid derived from the roots of trees penetrating down and afterwards decaying.

It is not unfrequently the case that the course of a sand pipe can be traced through the gravel and sand overlying it by its effect on the vegetable soil.

Sand Shot. In Artillery, small cast-iron balls; so called because they have always been cast in sand, while the larger shot used to be cast in iron moulds. They are used for grape and case, or are fired loose from a mortar.

Sandal Wood. The name of various odoriferous woods obtained from the genus *Santalum*. These woods formerly bore the name of Sanders Wood. White or Indian Sandal Wood comes from *S. album*; Yellow or Sandwich Island, from *S. Freycinetianum* and *S. paniculatum*; while Western Australia furnishes another kind in the wood of *S. latifolium*. What is called Red Sandal Wood is another thing, and is produced by *Pterocarpus santalinus*.

Sandals (Gr. σάνδαλον). A species of slippers worn by the ancient Jews, Greeks, and Romans. They consisted of a sole with a hollow part at one end, to embrace the ankle and leave the upper part of the foot bare. Originally sandals were made of leather; but they afterwards became articles of great luxury, being made of gold, silver, or other precious stuff, and beautifully ornamented.

Sandarach (Gr. σανδαράκη, *realgar*). A white brittle resin obtained from *Callitris quadrivalvis*. The powder of this resin is sometimes used, under the name of *pounce*, to prevent ink from sinking into paper. [CALLITRIS; JUNIPER.]

Sandbags. In Military operations, bags of coarse canvas filled with sand, much used in cases where cover for troops is required to be speedily obtained, as a temporary revetment for parapets, &c.

Sandbox-tree. The West Indian name for *Hura crepitans*.

Sandemanians. In Ecclesiastical History, a name given in England to a small body of Christians, who are termed Glasites in Scotland. In 1727, John Glas, a minister of the church of Scotland, published *The Testimony of the King of Martyrs concerning His Kingdom*

(John xviii. 36), in which he opposed national establishments, and described the Christian church with its doctrines, practices, officers, and discipline, as set forth in the New Testament. Having been deposed in 1728, he formed his followers into churches after the primitive models. In 1755, the publication of a series *of letters* by his son-in-law, Robert Sandeman, led to the formation of similar churches in London, and other places in England, and also in America, several of which still exist. The Sandemanians do not recognise the name given to them, and profess to hold no doctrines or observe any precepts but what are clearly enforced in the New Testament.

Sanderling. The name of a small wading bird, a species of *Tringa* (*Tr. arenaria*, Ill.), which frequents many of our shores, but not in great numbers.

Sanders Wood. [SANDAL WOOD.]

Sandiver. The impurities which collect upon glass during its fusion in the furnace are so called.

Sandpiper. A name applied to different species of the genus *Tringa*, but properly restricted to the *Tringa hypoleucus* of Linnæus, which is the type of the subgenus *Totanus*.

Sandstone. One of the three great divisions of the sedimentary rock masses, limestone and clay being the others. In Geology, sandstones belong to all geological periods, and exhibit almost infinite variety of detail, although with a degree of general resemblance not easily mistaken. They are mixed in all proportions with calcareous and argillaceous matter, thus passing into marls and loams, and forming vegetable soils. They sometimes contain so much oxide of iron as to pass into ironstones. Existing sometimes, quite uncemented, as loose sand, they also exhibit all degrees of cementation till in quartz rock or quartzite they are perfectly compact and have lost all granular texture.

Sandstones are presented in no regular order. Large tracts of country consist almost exclusively of such rock, and are very barren, but more usually other rocks alternate with them, and the mixture makes vegetable soil.

Sandstones are rarely fossiliferous. They are, however, remarkable as a group containing a peculiar kind of fossil, namely the imprint of animals that have walked over certain beds while the mass was being accumulated and before the sea-sand had passed into the state of stone. Such footmarks have been detected chiefly in the older secondary sandstones, especially the new red sandstone; as in the neighbourhood of Liverpool and in Warwickshire in England, in some parts of Scotland, in Connecticut and other northern states of America. They have been found much more sparingly in the Palæozoic sandstones. In all these cases the conditions under which the footmark has been left were probably similar. [FOOTPRINTS, FOSSIL.] In this kind of rock not only the deep footprints of large animals, but very small scratchings of crabs and worms, and probably other creatures, the marks of rain recently fallen, and the forms of seaweed have also been found accurately recorded.

Sandstones are valuable for building purposes. Some, especially those of which the cementing medium is silica, are extremely durable; others, cemented only by carbonate of lime or oxide of iron, are so rotten as not to be worth the expense of moving from the quarry. There are many intermediate qualities.

Many of the fine grits from the coal measures, with a little mica distributed through them and coloured with carbon of a faint grey, are both durable and easily worked. [BUILDING MATERIALS.]

Sandstones of which the particles are coarse, are called GRIT, and when made up of pebbles cemented together they are termed CONGLOMERATE or PUDDING STONE.

Sandwort. The common name for the weedy native genus of plants called *Arenaria*.

Sandyx (Gr. σάνδυξ). An old Alchemical term applied to red lead prepared by calcining carbonate of lead.

Sangiac. A Turkish officer, governor of a sangiacate, or district forming part of a pashalic. There were 290 such districts in the Turkish empire before the losses of territory on the side of Greece and the Caucasus. [PASHA.]

Sangreal or **Saint Graal** (the Holy Cup or vessel, said to be from Mod. Lat. gradale, *a cup*; but supposed by some to be a corruption of the Old French, le Sang Real, i.e. *the true blood* of Christ). This sacred relic, preserved in an emerald cup, is said in legendary history to have been brought to England by Joseph of Arimathæa. According to the romantic story of King Arthur, it could only be discovered by one possessed of perfect virtue; and the 'quest of the St. Graal' by the Knights of the Round Table, of whom the perfect champion, Sir Galahad (in other legends Perceval), was favoured by its discovery, is narrated therein at great length. [ROUND TABLE.]

Sanguinaria (Lat. Sanguinarius, from sanguis, *blood*). A genus of *Papaveraceæ* of some medicinal repute, common in the United States, and consisting of one species, *S. canadensis*, which bears the popular names of Puccoon and Blood-root, from the coloured juice present in the roots.

Sanguisorbeæ (Sanguisorba, one of the genera). An order or sub-order of herbaceous or undershrubby Exogens, usually combined with *Rosaceæ*, but sometimes regarded as distinct, on account of the constantly apetalous flowers, indurated calyx, and solitary or almost solitary carpels. Their general character is that of astringency. The *Sanguisorba officinalis*, or Burnet, is sometimes grown as a pasture plant.

Sanguisuges (Lat. sanguis, *blood*; sugo, *I suck*). The name of a family of Hemipterous insects, including those which suck the blood of animals: also applied to a family of Abranchiate Annelides, of which the leech (*Sanguisuga medicinalis*, Sav.) is the type.

Sanhedrim. The highest judicial tribunal among the Jews, consisting of seventy-one members, including the high priest. Its origin is referred by some writers to the institution by Moses of a council of seventy persons on the occasion of a rebellion of the Israelites in the wilderness. (Milman's *Hist. of Christianity*, i. 339, &c.)

Sanidine (Gr. *σανίς, a board*). A name given to Glassy Felspar, on account of the tabular form of its crystals. It is a transparent or translucent variety of Potash Felspar, white or of a greyish colour, with a very bright vitreous lustre, and occurs only in volcanic rocks.

Sanies (Lat.). A thin unhealthy discharge from wounds or sores.

Sans-culottes (Fr. *breecheslesss*). A name first given in ridicule to the Jacobins and other extravagant patriots in the French Revolution, and afterwards assumed by them as a title of honour; like the old nickname of *gueux* (*beggars*), in which the revolters of the Netherlands prided themselves. Camille Desmoulins appears to have been one of the first who rendered it popular, his blasphemous application of it at his trial is well known. It acquired great celebrity after the *journée* of the 20th June, 1792, when one of the principal standards borne by the insurgents was a pair of black breeches, with the inscription, 'Tremblez, tyrans! voici les Sans-Culottes.' Subsequently the French nation adopted it with the utmost gravity in the original Republican calendar. The five supernumerary days (the twelve months containing thirty a piece) were named Sansculottides; and were festivals dedicated to 'Genius,' 'Labour,' 'Actions,' 'Rewards,' 'Opinion.' In Leap years there was to be a sixth Sansculottide, the festival of the Revolution.

Sanscrit. The learned language of Hindustan, which had ceased to be a spoken language at least 300 B.C. The literal meaning of the word Sanscrita is *polished*, and it is used by grammarians in the sense of 'regularly inflected or formed.' (Colebrooke's *Remains*, vol. ii. p. 2.) It constitutes the most ancient literature of the Hindus, and is radically connected with the various dialects of Hindustan, so that they may be regarded as more or less deflected from it. In the Hindu drama, the gods and saints are made to speak in Sanscrit; while women, benevolent genii, &c., speak another dialect, and the lower personages a third. (H. H. Wilson, *Hindoo Theatre*, Introduction.) The attention of European enquirers was directed to the Sanscrit and its cognate language by Sir William Jones. Since his time the study has made great progress in England, where it has been especially furthered by the labours of Houghton, Wilkins, and Wilson; and more in Germany, where Frederic Schlegel (*Sprache, &c. der Indier*, 1808) was the first to excite the spirit of investigation. He was followed by his brother, A. W. Schlegel (who edited the *Bhagavat Gita*, translated into English by Mr. Wilkins) and many others. Among more recent German philologists, Bopp deserves the highest name for his researches in this direction. For the history of the language, and its relation to the other languages of the Aryan family, see Max Müller's *Lectures on the Science of Language*, p. 139, &c. [LANGUAGE; PRAKRIT.]

Sanseviera (after Sansevier, a Swedish botanist). A tropical genus of Liliaceous plants, remarkable for the toughness of the fibre embedded in their fleshy leaves, whence the plants obtain the name of Bowstring Hemps, the fibres of their leaves being used for bowstrings by the natives of the countries where they are indigenous. The genus is very closely allied to *Dracæna*. *S. guineensis* is the African Bowstring Hemp; *S. Roxburghiana* is the Moorva or Marool of the Indian peninsula. The fibre of the Moorva is very strong and of fine quality, and is suitable for the manufacture of fine string and cordage.

Santalaceæ (Santalum, one of the genera). A natural order of Epigynous Exogens, of the Asaral alliance, distinguished by the one-celled ovary, and the definite ovules having a coated nucleus. The species are sometimes herbs, sometimes shrubs and trees, and often grow parasitically on the roots of other plants. The typical genus is *Santalum*, which yields SANDAL WOOD.

Santalin. The colouring principle of red Sandal or Saunders wood, from which it is separated by digesting the rasped wood in alcohol, and then, on adding water to the tincture, it falls in the form of a bright red precipitate, soluble in alcohol and in alkaline solutions. A colourless crystalline substance has been separated from red sandal wood, and is described by Preisser under the name of *Santoline*, which by oxidisement and by the action of several chemical reagents acquires a red colour and is converted into what he terms *Santoléine*. But the existence of these colourless bases or sources of the above and other colouring matters requires further confirmation.

Santonin. A proximate vegetable principle, obtained from the flower-heads of *Artemisia santonica* and other species, known in pharmacy as *wormseed*. It is white, crystallisable, bitterish, and very little soluble in water, but more so in alcohol. It is occasionally used as a vermifuge in doses of from 10 to 30 grains, followed by a brisk purge. The so-called *wormseed* of the druggists, kept in the shops under the name of *semen cinæ*, and *semen contra* appears to be derived from several species of *Artemisia* and to be a mixture of broken peduncles, calyces, and flower-buds. The formula $C_{10}H_6O_2$ has been assigned to Santonin.

Saouari or Souari Wood. A valuable ship-building timber obtained from *Caryocar nuciferum* and *tomentosum*, trees which also yield the delicious souari nuts.

Sap (Fr. saper, Ital. zappare). In the attack of a fortress, the excavation of a trench under the

musketry fire of the besieged. When a sapper carries two gabions, and excavates the earth behind them, it is called a *flying sap*. When a squad of sappers works behind a *sap roller*, it is called a *single sap*. When the approach cannot be made by zigzags, and two single saps are carried on side by side directly towards the front, with a parapet on the outer side of each, it is called a *double sap*.

Sap (Lat. sapa, Gr. ὀπός). The fluid absorbed from the earth by the roots of plants, then sent upwards into the stem, and afterwards conveyed from the leaves, where it is assimilated and altered, to the bark. In its crude state it consists of little except water holding earthy and gaseous matter in solution, especially carbonic acid; but as it rises through the tissue of the stem it dissolves the secretions which it meets with in its course, and thus acquires new properties, so that by the time it reaches the leaves it is entirely different from its state when it first enters the root. The course taken by the sap in its passage through the stem is by the whole of the tissue included within the bark, provided it is all permeable; but as, in many plants, the central part of the stem becomes choked up with solid matter deposited in the tissue, it usually happens, especially in trees, that the course of the sap is confined to the outer part of the wood, hence called Sapwood. It is not certainly known through what kind of tissue the upward motion of the sap takes place, but it is probable that it is carried onwards through all the tubes and vessels of the wood and their intercellular passages. The dotted vessels of the wood seem more especially destined to fulfil this office when the sap is in rapid motion; but as they afterwards become empty, while the ascent of the sap continues, there can be no doubt that the woody tubes or pleurenchyma offer the most constant means by which the sap is conveyed.

Sap Ball. A local name for those *Polypori* which grow on trees, but applied more especially to *P. squamosus*, the stem of which when large, after the juice has been squeezed out, is sometimes used by boys as the foundation for tennis-balls. The same species is sometimes used, when properly dried and shaped, to form razor-strops.

Sap Fork. An instrument like a boat hook, used to push on a sap roller in sapping. [Sap.]

Sap Green. The inspissated juice of the berries of the buckthorn (*Rhamnus catharticus*). It is used by water-colour painters as a green pigment. It is the *vert de vessie* of the French. A colouring matter extracted from the excrement of the silkworm is also termed sap green.

Sap Roller. A large gabion, six feet long, and four in diameter, rendered bullet-proof by fixing another gabion six feet long by two and a half in diameter inside it, and filling up the space between with stout wooden pickets. [Sap.]

Sapan Wood. A dye wood produced by certain species of *Cæsalpina*—*C. Sappan*, *coriaria*, &c. It has long been used in India, and resembles Brazil-wood in its colour and properties.

Saphena (Gr. σαφής, *distinct*). The large vein of the leg which ascends over the external ankle.

Sapindaceæ (Sapindus, one of the genera). A natural order of Thalamifloral Exogens, consisting of exotic trees and shrubs, the larger part of which occur in South America. They usually have compound leaves and inconspicuous flowers, resembling those of European maples; and many of them are climbing plants. The order is poisonous in various degrees; nevertheless, the arillus of *Blighia sapida* is an esteemed fruit in Africa and the West Indies, where it is called the *Akee*. The most singular property observed in the order is that of having an astringent quality, and forming a lather when agitated in water, whence the name of the typical genus—from sapo, *soap*.

Sapodilla. The name of the *Sapota Achras*. Its timber, called Sapodilla Wood, is a fancy West Indian furniture wood.

Saponification (Lat. sapo, saponis, *soap*, and facio, *I make*). The formation of soap. It consists in the decomposition of fats, which consist of acids and glycerin, by alkalies which are chemically stronger than glycerin, and therefore displace it. Mere ebullition of the alkaline solution with the fat is usually sufficient to effect saponification. On adding salt to the resulting liquid, the soap is precipitated.

Saponin (Lat. sapo). A peculiar substance contained in the root of the *Saponaria officinalis*, and the fruit of *Sapindus Saponaria* and other species. It is the cause of the lather which the root and seeds of these plants form with water. A similar principle is found in Senega, Pimpernel, the Horse-chestnut, and in several varieties of *Lychnis*. An infusion of soapwort is sometimes used instead of soap for cleansing the finer varieties of wool.

Saponite. [Soapstone.]

Sapotaceæ (Sapota, one of the genera). A small natural order of Thalamifloral Exogenous trees inhabiting the West Indies and other tropical countries. In some cases they produce eatable fruits, known by the colonial names of Sapodilla, Marmalade Apple, Star Apple, Surinam Medlar, &c. The juice is white like milk; and, unlike the secretions of most lactescent families of plants, may be used for alimentary purposes. The fruit of some yields a greasy substance; whence one of them, *Bassia*, has gained the name of *Shea*, or Butter-tree, in Africa.

Sappare. A name which was given to Kyanite, by De Saussure, owing to a mistake in reading a label on which it had been incorrectly called Sapphire. Transparent blue Kyanite is sometimes polished and substituted for Sapphire, but is easily distinguished by its very inferior hardness.

Sappers and Miners. The name given to the non-commissioned officers and privates of the corps of Royal Engineers. Their duties

consist in building fortifications, in executing field works, &c., under the direction of their superior officers. [ENGINEERS, ROYAL.]

Sapphic. The name given to a species of verse; from Sappho, the famous Greek poetess, by whom it was said to be invented. It consists of eleven syllables of five feet, of which the following is a plan:—

–⏑ | –– | –⏑⏑ | –⏑ | –⏑ |.

This measure was afterwards introduced into Latin, and received great improvements in the hands of Horace and Catullus. The rules for the composition of Greek are much less strict than those for the composition of Latin sapphics. The sapphic strophe consists of three sapphic verses, followed by a *versus Adonicus*, or Adonian verse. [ADONIC.]

Sapphire (Gr. σάπφειρος). The name given to brightly coloured varieties of Corundum. The *blue* are generally called Sapphire; the *red*, Oriental Ruby. Sapphire consists essentially of crystallised alumina and is inferior in hardness only to the diamond. It occurs in variously terminated six-sided prisms and in rolled masses; and is found in the beds of rivers and associated with crystalline rocks, chiefly in Ceylon and Pegu; but it is also met with in Bohemia; near Expailly, in Auvergne; and in New South Wales. Sapphires have been used not only as ornamental stones but for the lenses of microscopes, for jewelling watches, and, when bored, for drawing very fine gold and silver wire. [CORUNDUM; STAR-STONE.]

Saprophagans (Gr. σαπρός, *putrid*, and φαγεῖν, *to eat*). The name of a tribe of Coleopterous insects, comprising those which feed on animal and vegetable substances in a state of decomposition.

Sapucaia Nuts. The seeds of *Lecythis Zabucajo*, imported from Pará, and commonly sold in the fruit shops. They somewhat resemble Brazil nuts, but are superior in flavour and more digestible.

Sapwood. The external part of the wood of Exogens, which, from being the latest formed, is not filled up with solid matter, or with the colouring principles which are deposited in wood after a certain time. For these reasons, sapwood is that through which the ascending fluids of plants move most freely; and not being solidified by the earthy and other substances eventually incorporated with wood, is quickly decomposed when exposed to the action of air and moisture. Hence for all building purposes the sapwood is, or ought to be, removed from timber. The sapwood or unsolidified wood of all trees is much the same in its power of resisting decomposition, that of the oak and lignum vitæ perishing as quickly as poplar and other valueless timber; and chemists have ascertained that if the hardest heartwood is reduced to its original condition of sapwood by the abstraction of the matter of solidification, all those properties which give heartwood its value are destroyed.

Sarabaites. Oriental monks or cœnobites, described by Cassian in his *Institutions*; and supposed to be the same with those called Remoboth by St. Jerome (*Epist.* xviii.).

Saraband (Span. zarabanda, Ital. sarabanda). In Music, a composition in triple time very similar to a minuet. When denoting music for the dance, it is to the same measure which usually terminates when the beating hand rises; being thus distinguished from the *courant*, which ends when the hand falls.

Saracenic Art. A style allied to the Byzantine, being developed by Byzantine Greeks for the Arabs. The details are composed of conventional flowers and tracery, with ingenious variations of the early Christian symbolism disguised. Its great feature is the exclusion of all imitation of nature. (Owen Jones's *Alhambra*; Wornum's *Analysis of Ornament, &c.*) [DECORATION; ORNAMENT.]

Saranyû. [ERINYS.]

Sarcocarp (Gr. σάρξ, *flesh*, and καρπός, *fruit*). In Botany, the fleshy part of a pericarp, lying between the epicarp and endocarp.

Sarcocele (Gr. σαρκοκήλη, from σάρξ, and κήλη, *a tumour*). A tumefaction of the testicle.

Sarcocol (Gr. σαρκοκόλλα, *a Persian gum*). A gum resin, said to be the produce of *Pœnea Sarcocolla*, a plant growing in the northern parts of Africa. This Sarcocol somewhat resembles gum arabic; but is soluble in alcohol, and its aqueous solution is precipitated by tannin.

Sarcocollin. A gummy matter contained in commercial *sarcocolla*, the dried juice of the *Pœnea mucronata*.

Sarcode (Gr. σαρκώδης, *flesh-like*). The organised substance of which the soft parts of Protozoa (Sponges, Infusories, Foraminifers) are composed.

Sarcoderm (Gr. σάρξ, and δέρμα, *skin*). In Botany, an intermediate fleshy layer found in the testa of some seeds.

Sarcolite (Gr. σάρξ, and λίθος, *stone*). A pale, flesh-coloured Zeolite, found in small semi-transparent crystals at Monte Somma; with Wollastonite, Hornblende, &c. It is a silicate of alumina, lime, and soda.

Sarcology (Gr. σάρξ, and λόγος, *a discourse*). The history or doctrine of the fleshy parts of the body.

Sarcophagus (Gr. σαρκοφάγος, from σάρξ, and φαγεῖν, *to eat*). In Antiquities, a stone receptacle for a dead body. The name originates in the use of the lapis Assius, stone of Assos (in Asia Minor), said to have been prepared for this purpose, on account of its supposed property of corroding dead bodies, so as to consume them entirely in forty days; which, together with other incredible qualities, is ascribed to it by Theophrastus and Pliny. One of the most celebrated specimens of this object of art is the great sarcophagus taken by the British in Egypt in 1801, commonly called that of Alexander: it is deposited in the British Museum. Dr. Clarke, the traveller, wrote an essay to prove that the Macedonian conqueror

had really been entombed in it; but this opinion seems unfounded.

Sarcosine (Gr. σάρξ). A basic substance obtained by boiling kreatin with hydrate of baryta. Its formula is $C_6 H_7 O_4 N$.

Sardines. Small fishes of the Herring family (*Clupea sardina*, Cuv.), taken in vast numbers off the coast of Sardinia, and in other parts of the Mediterranean, where the herring is unknown. They form an important article of commerce, their flavour being highly esteemed.

Sardonic Laugh. [Risus Sardonicus.]

Sardonyx (Gr. σαρδόνυξ). Onyx consisting of alternate layers of Sard and nearly opaque-white Chalcedony. It is the most beautiful and the rarest variety of Onyx, and that which was held in the greatest esteem by the ancients for engraving into cameos. The Sardonyx is found in Perthshire.
